With multipin technology, peptides are synthesized in parallel on plastic "pins" (Fig. 18.2.2) to give sets of peptides suitable not only for B and T cell epitope scanning but also for other bioassays. Peptides can be either permanently bound to the surface of the plastic for direct binding assays, or they can be released into solution. There is a choice of N- and C-terminal peptide endings. For solution-phase peptides, the synthesis scale can be 1 or 5 μmol (for a 10-mer, ~1 mg or 5 mg, respectively). The preferred coupling/deprotection chemistry used is the milder 9-fluorenylmethyloxycarbonyl (Fmoc) protection scheme rather than the older *t*-butyloxycarbonyl (*t*-Boc) protection scheme (see *UNIT 18.1*), thus reducing the level of chemical safety risk arising from synthetic peptide chemistry.

This unit covers the strategy of the multiple peptide approach to biological scanning, the synthetic protocols, and the handling of peptides after synthesis—cleavage, preliminary purification, storage, and analysis (see Basic Protocol). It is specific for the multipin technique using equipment obtained from Chiron Technologies, although some of the approaches are applicable to other multiple synthesis techniques. Procedures for multipin equipment obtained from other suppliers may differ from the procedures described here, and the manufacturer's literature should be consulted. This unit also includes protocols for preparing Fmoc–amino acid solutions (see Support Protocol 1) and for acetylating (see Support Protocol 2) or biotinylating (see Support Protocol 3) synthesized peptides.

STRATEGIC PLANNING

For a protein whose primary structure is known, the conceptually simplest method of locating all the bioactive linear peptide sequences is to make all possible peptide subsets of the protein sequence and test them. If only selected parts of the sequence are synthesized, or only the predicted active parts, bioactive sequences could be missed. The use of a set of highly overlapping peptides likewise reduces the possibility that the most bioactive sequences might be missed because they are absent from the set. A set of all overlapping 20-mers offset along the sequence by one residue at a time should capture the entire set of, for example, helper T cell epitopes, and this is a much more reliable approach than trying to predict motifs. In reality, a synthetic peptide scan through a protein is a compromise between the cost and effort in making and screening all peptides and the

BOWLING GREEN STATE UNIVERSITY LIBRARY

need for completeness. Thus, one worker may choose to make all overlapping 8-mers to find the linear (continuous) B cell epitopes, and another may make 12-mers offset along the sequence by five residues for the same purpose. In each case, all sequences of eight residues from the protein are present in at least one peptide, but the latter approach requires only one-fifth the number of peptides.

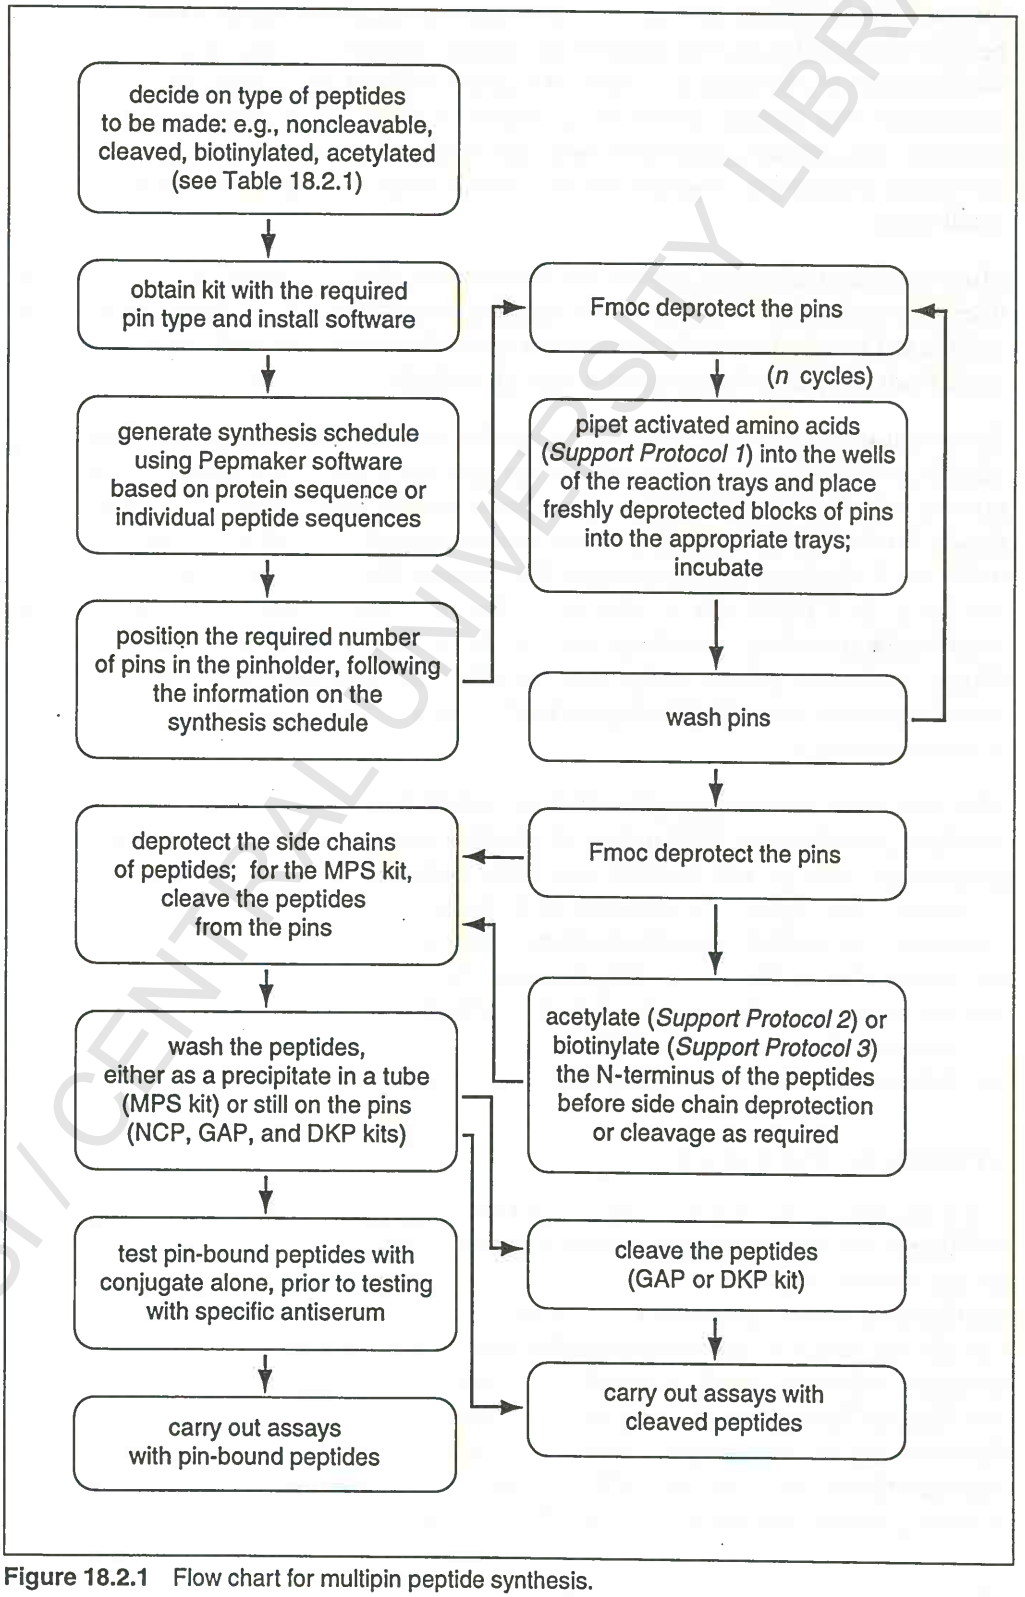

Figure 18.2.1 Flow chart for multipin peptide synthesis.

PCU IASI / CENTRAL UNIVERSITY LIBRARY

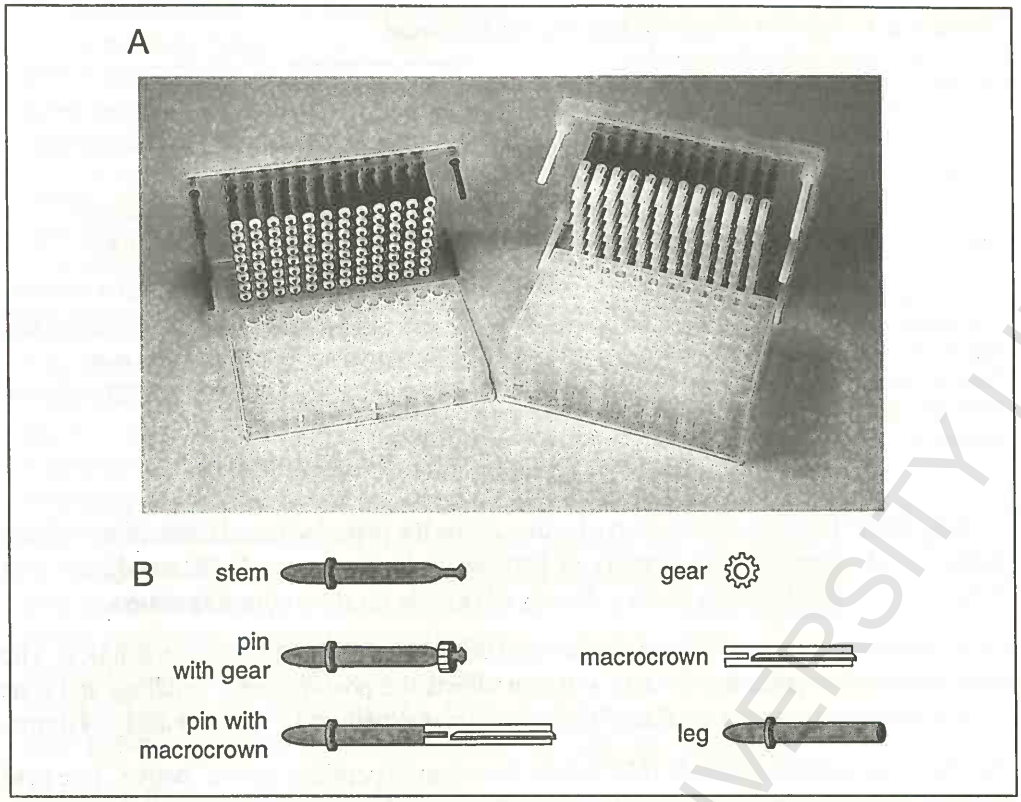

Figure 18.2.2 Apparatus for multipin peptide synthesis. (**A**) Assembled synthesis block with 96 gears (left) or 96 macrocrowns (right). (**B**) Components of the pin assembly. Components are either push-fitted together (e.g., legs or stems into the pin holder) or clipped on (gears or macrocrowns onto stems). All components are solvent-resistant plastic, either polyethylene, polypropylene, or copolymers of these two monomer types.

Planning the Synthesis

Synthetic peptides are assembled by solid-phase synthesis one amino acid at a time, commencing with the C-terminal end of the peptide on the solid phase (see *UNIT 18.1*).

The assembly process, or coupling, requires activation of the α-carboxyl group of each incoming amino acid to make it reactive with the α-amino group of the growing peptide chain. To prevent unwanted polymerization or side reaction, reactive groups in each amino acid must be temporarily protected, and the protecting group removed before further reaction can be carried out. The protecting group on the α-amino function of the most recently added amino acid must be removed before another amino acid can be coupled to it, so the α-amino protection must be labile under conditions that do not remove side-chain protection. Later, the side-chain-protecting groups must be removable under conditions that do not attack the peptide bonds. The two common protecting group "schemes" are known as *t*-butoxycarbonyl (*t*-Boc) or 9-fluorenylmethyloxycarbonyl (Fmoc). The protecting group scheme currently recommended for multipin peptide synthesis is the milder Fmoc scheme, which is the only scheme described in this chapter.

Before beginning to plan the actual synthesis in detail, a choice needs to be made regarding how the peptides will eventually be presented in the bioassay. The options available to investigators are listed in Table 18.2.1.

For noncleavable peptide (NCP) kits, peptides are permanently bound on the solid phase (pin surface) and can be used for direct binding assays but not for interaction with living cells or other complex (e.g., multicomponent) systems. In this case, the peptides must be

BOSTON CENTRAL UNIVERSITY LIBRARY

Table 18.2.1 Types of Pins for Multipin Peptide Synthesis[a]

Name	Linker[b]	Physical format[c]	Loading	Final form of peptide
NCP	Noncleavable	Gear	50 nmol	(N-capping)-PEPTIDE-linker-pin
MPS	AA ester	Macrocrown	5 μmol	(N-capping)-PEPTIDE-acid
MPS	Rink amide	Macrocrown	5 μmol	(N-capping)-PEPTIDE-amide
DKP	DKP-forming	Gear	1 μmol	(N-capping)-PEPTIDE-DKP
GAP	Glycine ester	Gear	1 μmol	(N-capping)-PEPTIDE-glycine-acid

[a]Abbreviations: DKP, diketopiperazine; GAP, glycine acid peptide; MPS, multiple peptide synthesis; NCP, noncleavable peptide; (N-capping), a free amine, acetyl group, or biotin; PEPTIDE, the sequence of the peptide being made.

[b]Nature of linker between peptide and graft polymer on the pin: noncleavable linker, β-alanine-hexamethylenediamine; DKP, diketopiperazine; AA ester, amino acid ester; Rink amide, Rink amide–forming linker.

[c]See Figure 18.2.2B.

"regenerated" between repeat assays by disrupting the peptide-ligand interaction without damaging the peptide. The quantity of peptide made is very small (50 nmol), but it is sufficient to provide a high surface density of peptide for direct binding assays.

In the other options, peptides are synthesized on pins and then released into solution. The mechanism of peptide release into solution affects the postsynthesis handling and thus the suitability of peptides produced by each cleavage method for various assay systems.

For multiple peptide synthesis (MPS) kits, the released peptides have a "native" free acid or an amide carboxy terminus. To make free acid C-termini, it is necessary to use macrocrowns that already have the first (C-terminal) amino acid on them because the chemistry of forming the first (ester) link is too difficult for the inexperienced user. In contrast, the Rink amide linker allows formation of a peptide with a C-terminal amide of any amino acid by adding the C-terminal amino acid to the Rink handle macrocrown using the standard amino acid coupling protocol. A Rink amide linker is a linker that can accept an amino acid but then can be cleaved in trifluoroacetic acid (TFA) to release the amide form of that amino acid (Rink, 1987). Although acid or amine endings are often the most desirable peptide format to have, they are also the most complex to produce because the cleavage of the peptides from the pin is into neat TFA plus scavengers which needs to be evaporated to recover the peptide. The scale of peptide synthesis for MPS kits is 5 μmol (~5 mg of a decamer).

For glycine acid peptide (GAP) kits, peptides with a glycine at the carboxy terminus are cleaved as the free acid, so that the C-terminal residue is a natural amino acid (glycine) and is not blocked. The peptides are also relatively simple to release from the pin and require little postsynthesis handling. However, the presence of glycine at the C-terminus may be undesirable where the C-terminus plays an important role in peptide bioactivity. The scale of synthesis for GAP kits is 1 μmol (~1 mg of a decamer).

In diketopiperazine (DKP) kits, peptides are synthesized with a DKP group at the C terminus. The DKP group is a cyclic dipeptide formed from C-terminal lysine and proline residues during the facile cleavage of the peptide under the mildest possible conditions: neutral aqueous buffer. In applications where the presence of the DKP group is acceptable, this type of peptide can make the downstream processing of synthetic peptides very simple and fast. The peptides can be placed into a bioassay system immediately after completing the cleavage. The scale of synthesis for DKP kits is 1 μmol (~1 mg of a decamer).

For these five kit options, it is also possible to choose a variety of N-terminal endings on the peptides. For example, it may be desirable to acetylate pin-bound peptides (see Support Protocol 2) to eliminate the positive charge that would otherwise be present on

RCU IAS / CENTRAL UNIVERSITY LIBRARY

the α-amino group of the N-terminal residue, or to enhance the activity of a peptide in a T helper assay (Mutch et al., 1991). A handy option for cleaved peptides is to place a biotin group on the N-terminus (see Support Protocol 3) so the peptide can be captured using avidin or streptavidin. These additions must be made prior to side-chain deprotection of the peptides.

There are other configurations for multiple peptide synthesis—e.g., the SPOTS or "peptides on paper" system (Zeneca/CRB), the RaMPS system (DuPont), and multi-synthesizer machines (e.g., Advanced ChemTech).

Assessing Peptide Sequences

Peptides differ so much in properties that it is important to assess the likely properties of the peptides before attempting to synthesize them. Peptide length and hydrophobicity are the two main attributes affecting successful synthesis. The longer the peptide, the lower will be the purity of the product, as each amino acid coupling cycle is never 100% efficient. Synthesis of peptides longer than 20 residues should be avoided unless special attention can be given to each sequence. Hydrophobic peptides may be difficult to synthesize, but more significantly they may be poorly soluble in aqueous buffers, restricting their ultimate usefulness in bioassays. Prior to beginning synthesis of a set of peptides, it is sensible to assess them all for hydrophobicity (Fauchere and Pliska, 1983; *UNIT* 2.2) and decide if all should be attempted as they stand. In many cases, it is possible to choose slightly different peptides (longer, shorter, or using a different starting and finishing point in the homologous protein sequence) that will have more user-friendly properties.

As well as these general factors affecting peptides, particular peptide sequences may have characteristics that make them difficult to synthesize, or they may be problematic after synthesis. It is not feasible to discuss all the common problems here. To help assessment of peptide sequences, a software application called Pinsoft is available free from Chiron Technologies. This allows any sequence to be typed in, and an assessment is automatically reported.

Generating Peptide Sequences

Computer software (Pepmaker) supplied with synthesis kits allows sets of overlapping peptide sequences to be generated from a protein sequence computer file using the single-letter amino acid code. Alternatively, sequences can be created using a word processor and the resulting computer text file can then be used by Pepmaker to guide synthesis. The use of this software simplifies the otherwise complex and tedious task of adding the right amino acids to each reaction plate on each synthesis cycle.

MULTIPIN SYNTHESIS OF PEPTIDES

BASIC PROTOCOL

Derivatized pins with macrocrowns or gears are attached to a pin holder. Each peptide is built up on the reactive surface of one pin by successive cycles of amino acid coupling, followed by washing and removal of the 9-fluorenylmethyloxycarbonyl (Fmoc) amino-protecting group to prepare for the next amino acid coupling cycle. A critical step is properly dispensing activated amino acid solutions into the appropriate wells of each reaction tray. A list of the well locations for dispensing of each amino acid is generated by the Pepmaker software for this purpose. When the peptides are complete, trifluoroacetic acid (TFA) that contains scavengers is used to remove the side-chain-protecting groups, and for MPS kits, to cleave the peptides from the pins. The manual provided with each type of kit (see Table 18.2.1) includes instructions and hints for kit-specific procedures.

NOTE: All reagents should be of the highest grade possible, preferably peptide synthesis or analytical reagent grade.

BOSTON UNIVERSITY LIBRARY

Materials

20% (v/v) piperidine/dimethylformamide (DMF; see recipe)
DMF, analytical reagent grade
Methanol, analytical reagent grade
100 mM activated 9-fluorenylmethyloxycarbonyl (Fmoc)–protected amino acid solutions (see Support Protocol 1)
Side chain deprotecting (SCD) solution (see recipe)
Acidified methanol: 0.5% (v/v) glacial acetic acid/methanol
1:2:0.003 (v/v/v) ether/petroleum ether/2-mercaptoethanol (2-ME)
1:2 (v/v) ether/petroleum ether
0.1 M NaOH
0.1 M acetic acid
0.1 M sodium phosphate buffer, pH 8.0 (*APPENDIX 2E*)
Sonication buffer (see recipe)

Peptide Synthesis Starter Kit (e.g., Chiron Technologies) of the desired type, containing:
  Pepmaker computer program and ELISA reading and plotting programs
  Manual
  Pins with gears or macrocrowns
Storage boxes or sealable bags, polyethylene or polypropylene (ICN Biomedicals)
Pipettor tips, polyethylene or polypropylene (ICN Biomedicals)
0.3- or 1.5-ml reaction trays, polyethylene or polypropylene (Chiron Technologies, Nunc, or Beckman)
Sonicator with power output of ~500 W
Dry nitrogen
Rack containing 96 1-ml polypropylene tubes (Bio-Rad)
10-ml capped conical polypropylene centrifuge tubes

Additional reagents and equipment for N-terminal acetylation (see Support Protocol 2; optional) or biotinylation (see Support Protocol 3; optional)

CAUTION: Perform all chemistry steps in a well-functioning chemical fume hood. Wear solvent-resistant gloves, safety glasses, and protective clothing. The reagents can be flammable, toxic, and/or carcinogenic. Avoid sources of contamination which may affect the pins, including direct contact with the bench surface or exposure to vapors. The reagents for multipin synthesis can be handled in unsealed systems, but the amount of time that these reagents are left exposed to the open air should be minimized by using capped containers for liquids or polyethylene bags for pins wherever practical. Local regulations for safe disposal of solvents and used reagents must be followed.

Prepare synthesis schedule and equipment

1. Use the Pepmaker computer program according to the instructions to generate the required set of peptide sequences (Fig. 18.2.3). Generate the printouts, which show for each coupling cycle how much of each amino acid solution, catalyst, and activating agent needs to be prepared (see Fig. 18.2.4) and where each amino acid solution is to be added to the reaction tray (see Fig. 18.2.5).

   The standard microtiter plate layout is an 8 × 12 matrix, in which the eight rows are identified as A through H and the twelve columns are identified as 1 through 12. However, the Pepmaker software uses a designation in which the column number is given first followed by a number designation for the row, beginning with row H, given in parentheses—i.e., 1(1) for well H1, 1(2) for well G1, 2(1) for well H2, and 12(8) for well A12 (see Fig. 18.2.6).

ECU IASI CENTRAL UNIVERSITY LIBRARY

2. Label each pin holder block indelibly on the top (e.g., Synthesis #1, Block A, Synthesis #1, Block B, and so forth), preferably by scratching into the plastic with a sharp tool. Place the label where it will help orient the block so that the pins are not accidentally placed into amino acid solutions in an inverted orientation. For example, keep pin H1 and well H1 at the lower left corner of the block (Fig. 18.2.6).

Ink labels will run or disappear with exposure to solvents.

The multipin system is based on the standard microtiter plate layout. The ***block*** *is the complete unit and consists of the* ***pin holder****, which is the support that holds 96* ***pins*** *(in an 8 × 12 array with standard ELISA microtiter plate spacing), and five* ***legs*** *to support the device and correctly position the active surfaces. A pin consists of an inert* ***stem*** *that supports either a* ***gear*** *or a* ***macrocrown****, both of which have an active surface on which the peptide is synthesized (see Figure 18.2.2). A gear is a detachable gear-shaped unit that fits on the thin end of a stem. A macrocrown is a detachable, vaned tip that fits on the thin end of a stem. It is made of high-density polyethylene and the surface is derivatized to give a solvent-compatible polymer matrix. Macrocrowns are provided in two forms: one has a linker that cleaves to give peptides with an amide at the carboxy terminus; the other has a linker that cleaves to give the free acid at the carboxy terminus and is supplied with an amino acid already attached to the linker. The* ***reaction tray*** *used for the synthesis is a polyethylene or polypropylene tray consisting of 96 wells in the standard microtiter plate 8 × 12 matrix. Shallow reaction trays (0.3-ml) are used with gears and deep trays (1.5-ml) are used with macrocrowns.*

3. Remove any pins that are not required for the first cycle of amino acid coupling and store them dry in a plastic bag in the refrigerator until needed.

Some pins need to be removed when the peptides in the synthesis are of various lengths because the software is designed to arrange all peptides to complete their synthesis on the same (final) coupling cycle. This approach eliminates unnecessary Fmoc–deprotection cycles for pins that are designated to carry the shorter peptides. The synthesis printout from the Pepmaker software shows which pins need to be added for each cycle of amino acid addition (Fig. 18.2.5). Pins (stems) can be pushed out from the top side of the pin holder. In the case of the MPS kit, where the first amino acid is already on the macrocrown as supplied, choose and mount the correct macrocrown for each position on the block.

Deprotect α-amino groups

4. Add 20% piperidine/DMF to a bath and place the pins in the bath so that the tips (macrocrowns or gears) are covered. Cover and let stand for 20 min at room temperature.

CAUTION: Piperidine is flammable.

The volume of reagent needed for all the bath steps depends on the shape of the bath, the critical factor being that all surfaces of the pins (i.e., the gears or macrocrowns) bearing the peptide need to be totally covered. A small bath suitable for gears is the upturned polypropylene lid of a pipettor tip box. For macrocrowns, deeper baths or deep-well polypropylene trays as supplied with the kit can be used.

5. Remove the block from the bath, shake off the excess liquid, and then wash the pins in a DMF bath for 2 min at room temperature.

Again, the DMF must fully cover the tips.

6. Shake off the excess DMF and immerse the block completely in a deep bath of methanol for 2 min so that all surfaces of the block are washed.

CAUTION: Methanol is flammable and toxic.

In a shallower bath the block can be turned over so that the pin holder part is washed as well.

Figure 18.2.3 *(above and at right)* A portion of the synthesis schedule worksheets generated by Pepmaker software for Schedule no. 1 for synthesis of a set of all possible overlapping octamers of sperm whale myoglobin. **(A)** This page of the synthesis schedule is a summary of the features of the protein including its sequence. **(B)** This page of the synthesis schedule shows the sequences of the first 96 peptides that will be synthesized, the first two of which are the controls, PLAQGGGG and GLAQGGGG. Peptide sequences are shown in the conventional amino-to-carboxy-terminal direction (from left to right), with a "<" sign indicating the end attached to the solid phase during synthesis. Because amino acid couplings are carried out in the carboxy-to-amino direction, the first amino acids coupled are at the right-hand end of each sequence, adjacent to the "<".

7. Place the block in a second methanol bath to fully cover the tips. Wash for 2 min. Repeat this washing step again with a fresh methanol bath for a total of three methanol washes.

8. Remove the block and allow it to air dry in an acid-free fume hood for a minimum of 30 min.

   Avoid exposure to acidic fumes as this could prevent efficient coupling in the next step.

   The block can be conveniently left to dry while the amino acid solutions are being dispensed.

Dispense activated amino acid solutions

9. Dispense the required volume of each activated amino acid solution (see Support Protocol 1; 150 µl for gears or 450 µl for macrocrowns) into the appropriate wells of the reaction tray as specified by the synthesis schedule for the coupling cycle (e.g., Fig. 18.2.5).

Perform the amino acid coupling

10. Place the pins in the activated amino acid solutions in the reaction tray, ensuring that the block is correctly oriented before actually lowering the pins into the solution. Incubate ≥2 hr at 20° to 25°C in a polyethylene box with a lid or in a sealable polyethylene bag.

    Coupling begins immediately and is irreversible.

Wash the pins

11. Remove the block of pins from the amino acid solutions and, if the next cycle is to start immediately, place the block in a methanol bath in which the pins are immersed to half their height (tips are fully immersed). Wash with agitation for 5 min. Flick off excess methanol and allow to air dry for 2 min.

12. Place the block in a DMF bath in which the pins are immersed to half their height (tips are fully immersed). Wash with agitation for 5 min.

    If extra pins are to be added as synthesis progresses (if the peptides being made differ in length), add the pins to the appropriate spaces (see Fig. 18.2.5).

13. Repeat steps 4 through 12 for each cycle of amino acid addition. Follow the synthesis schedule for preparing Fmoc–protected amino acid solutions and for depositing

Figure 18.2.4 This page of the synthesis schedule is used for the preparation of activated amino acid solutions. It shows the amounts of each amino acid (represented by the single letter code, A through Y, along the left-hand margin), activator (diisopropylcarbodiimide [DIC] in dimethylformamide [DMF]), and catalyst (additive; 1-hydroxybenzotriazole [HOBt] in DMF) needed for the first amino acid coupling cycle. (In this example the amounts are calculated for a 250-µl reaction volume.) The amino acid powder is dissolved in the HOBt/DMF solution (right-hand column) before activation with DIC/DMF solution.

Figure 18.2.5 This page of the synthesis schedule identifies which wells of the reaction tray receive which activated amino acid solution. Each amino acid solution is identified along the left-hand margin using the single-letter amino acid code. Individual reaction trays and pin holders (A or B in this case) are identified by letters of the alphabet, and the paired numbers—e.g., 10(1) for well 10H—identify individual wells within reaction trays according to the numbering system illustrated in Figure 18.2.6.

BIASI/CENTRAL UNIVERSITY LIBRARY

aliquots of the activated amino acids to the appropriate wells of the reaction tray for each cycle.

Two coupling cycles can be carried out during a normal working day, and a third coupling can be carried out overnight, so a total of three amino acids can be added to each pin during a 24-hr period.

14. Deprotect the final Fmoc amino acid by repeating steps 4 through 8. Then proceed with step 15 or step 16.

15. *Optional:* For B cell epitope scanning or for T helper cell epitope scanning, the N-terminus of the peptide can be capped by acetylation (see Support Protocol 2). To allow later recapture onto avidin, the N-terminus of the peptide can be capped with biotin or long-chain biotin (see Support Protocol 3).

Deprotect the side chains

16. Dispense the required volume of SCD solution into a bath or tubes (1.5 ml/tube) and fully immerse the peptide-bearing portion of the pins. Cover bath or cap tubes and incubate 2.5 hr at 20° to 25°C.

CAUTION: SCD solution is a toxic, corrosive liquid.

For blocks where the peptide is to remain attached to the pin during side chain deprotection (i.e., NCP, GAP, and DKP kits), side chain deprotection is carried out in a bath of reagent. For pins where the peptide is simultaneously side chain deprotected and cleaved from the pin (MPS kits), the process is carried out in individual 10-ml capped conical polypropylene centrifuge tubes that become the containers for the recovered peptide.

17a. *For NCP, GAP, or DKP kits:* Wash the pins 3 times in acidified methanol to remove the SCD solution prior to further treatment.

17b. *For MPS kit:* In a good chemical fume hood, reduce the volume of SCD solution containing cleaved peptide to ~0.1 ml either with a gentle stream of dry nitrogen gas or in a centrifugal vacuum drier (e.g., Speedvac) equipped to handle corrosive fumes. Precipitate the peptide in the remaining solution with 8 ml of 1:2:0.003 ether/petroleum ether/2-ME. Decant and discard the supernatant, and wash the

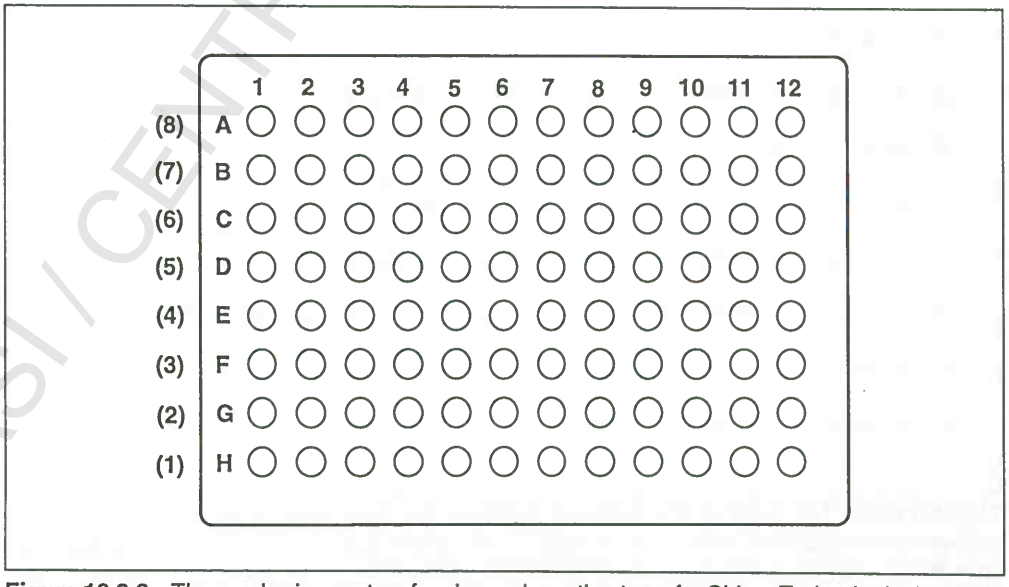

Figure 18.2.6 The numbering system for pins and reaction trays for Chiron Technologies' multipin synthesis system. Each well is identified by a pair of numbers rather than a number and a letter, e.g, 1(1). The first number identifies the column number; the second (in parentheses) identifies the lettered row, beginning with H as (1) and ending with A as (8).

ECU IAST / CENTRAL UNIVERSITY LIBRARY

precipitated peptide with 4 ml of 1:2 ether/petroleum ether. Dry the precipitate with a gentle stream of dry nitrogen.

CAUTION: Ether/petroleum ether/2-ME and ether/petroleum ether solutions are highly flammable.

These dry peptides can now be redissolved for assay purposes or may be further purified, e.g., by HPLC (see UNIT 11.6).

Prepare the peptides

18a. *For GAP kits:* Add 0.7 ml of 0.1 M NaOH to each tube of a rack of 96 1-ml polypropylene tubes. Place the pins into the solution and incubate ~1.5 hr to cleave the peptides from the pins. Immediately after cleavage, neutralize with one equivalent of 0.1 M acetic acid.

Alternatively, the 0.1 M NaOH solution can contain 40% (v/v) acetonitrile to facilitate solubilization of the more hydrophobic peptides.

The incubation time can be shorter if the tubes are sonicated during cleavage.

18b. *For DKP kits:* Cleave the peptide from the pin in a suitable, reasonably well-buffered solution with a pH >7 overnight (16 hr).

The solution for cleavage—e.g., 0.1 M sodium phosphate, pH 8, or 0.1 M HEPES, pH 8—can be chosen to be compatible with the assay for which the peptides will be used; the solution should have a buffering capacity of ~0.05 M.

Again, an organic modifier such as acetonitrile can be added to the cleavage solution to facilitate solubilization of the more hydrophobic peptides.

18c. *For NCP kits:* Prepare the pins for binding assays by floating the block, pin-side down, in sonication buffer and sonicating 10 min at ~60°C. Rinse the pins first in water, then in 20° to 45°C methanol for immediate use in an assay or air dry the pins for storage until they are used in an assay.

PREPARING ACTIVATED Fmoc–PROTECTED AMINO ACID SOLUTIONS

SUPPORT PROTOCOL 1

Activated 9-fluorenylmethyloxycarbonyl (Fmoc)–protected amino acid solutions are prepared in two steps. First, the protected amino acid is dissolved in a solution of the catalyst, 1-hydroxybenzotriazole (HOBt) in dimethylformamide (DMF). Then, just before dispensing, the amino acid is activated by adding an activating agent. The following procedure illustrates the use of diisopropylcarbodiimide (DIC) as the activating reagent. DIC is a liquid and can be measured by volume.

***Additional Materials** (also see Basic Protocol)*

9-fluorenylmethyloxycarbonyl (Fmoc)–protected amino acids with side-chain-protecting groups (Sigma, Bachem, Novachem, or Chiron Technologies), stored at 4°C
Catalyst: 1-hydroxybenzotriazole (HOBt)
Activating agent: diisopropylcarbodiimide (DIC)
Dimethylformamide (DMF), amine-free
Ethanol, analytical reagent grade
5- or 10-ml glass, polyethylene, or polypropylene bottles with inert (e.g., polythylene, Teflon) lids and liners

1. Remove the Fmoc–protected amino acids from the refrigerator and allow them to come to room temperature before weighing them out.

Warming the containers to room temperature avoids the possibility of uptake of moisture from the air onto the cold solids.

BCU MSC GENERAL UNIVERSITY LIBRARY

The side chains of the amino acids must also be protected during peptide synthesis: t-butyl ether is used for serine, threonine, and tyrosine; t-butyl ester is used for aspartic acid and glutamic acid; t-butoxycarbonyl (t-Boc) is used for lysine, histidine, and tryptophan; 2,2,5,7,8-pentamethylchroman-6-sulfonyl (Pmc) is used for arginine; and trityl (Trt) is used for cysteine. If benzotriazolyl-N-oxytris(dimethylamino)phosphonium hexafluorophosphate (BOP) or benzotriazol-1-yl-oxytripyrrolidinophosphonium hexafluorophosphate (PyBOP) activation is to be used, trityl protection should be used for asparagine and glutamine. BOP and PyBOP require greater care in handling and different protection should be used for some amino acids.

2. Weigh individual amino acids and HOBt using the quantities specified for the current synthesis cycle (e.g., see Fig. 18.2.4) into separate appropriately sized clean and dry glass, polyethylene, or polypropylene bottles. Rinse the spatula with ethanol and dry it after weighing each reagent.

   The bottle caps and inserts must be inert to any of the reagents or solvents used in making up the activated solutions (they must be Teflon, not rubber).

   Care should be taken to avoid cross-contamination of amino acids by rinsing the spatula in ethanol between weighings (the spatula must be dry before each use) and by making sure that all lids, as well as the containers, are labeled so they can be replaced on the correct bottles after weighing has been completed.

3. Measure the appropriate amount of DIC (see "Activator" as in Fig. 18.2.4).

   DIC is a liquid so it is more convenient to measure it by volume rather than by weight. Multiply the indicated weight by 1.23 (based on the density of DIC, 0.815 g/ml) as a conversion factor from the calculated weight to get the required volume of DIC in microliters.

4. Prepare HOBt and DIC solutions, by pipetting the appropriate volumes of purified (amine-free) DMF as shown on the synthesis schedule (e.g., see Fig. 18.2.4).

   Both reagents should be fully dissolved in the DMF before using them to prepare the activated amino acid solutions.

5. Add the specified volume of HOBt/DMF solution (e.g., Fig. 18.2.4, column headed "HOBt") to the individual amino acids.

   Make sure the amino acids are completely dissolved before adding the activator solution.

   Unactivated amino acid solutions may be stored a few days at 4°C.

6. Activate the individual amino acid solutions by adding the specified volume of DIC/DMF solution to each amino acid solution (e.g., Fig. 18.2.4, column headed "DIC"). Mix thoroughly and use immediately for peptide synthesis.

   Activated amino acids should be prepared immediately before use and any excess should be discarded.

SUPPORT PROTOCOL 2

N-TERMINAL ACETYLATION OF PEPTIDES

N-terminal capping of the peptides is carried out after a final 9-fluorenylmethyloxycarbonyl (Fmoc)–deprotection cycle and prior to side chain deprotection. The process is similar to coupling of amino acids, except that in the case of acetylation the active reagent can be acetic anhydride rather than acetic acid. Acetic anhydride does not require activation. If acetic anhydride is not available, simply use acetic acid as if it were an amino acid (see Support Protocol 3).

Additional Materials (also see Basic Protocol)

Acetylation solution (see recipe), prepared just before use
Pins with completed peptides (see Basic Protocol)

BCU IASI CENTRAL UNIVERSITY LIBRARY

1. Add freshly prepared acetylation solution to appropriate bath container.
2. Immerse the pins with completed peptides in acetylation solution and incubate 90 min at room temperature.
3. Wash the pins in a methanol bath and air dry.

The pins can now be used for side chain deprotection (Basic Protocol, step 16).

N-TERMINAL BIOTINYLATION OF PEPTIDES

SUPPORT PROTOCOL 3

Biotin can also be coupled to the N-terminus of peptides after N-terminal deprotection and before side chain deprotection. The reagent is used as if it were an amino acid, using the same solvent, activating agent, and catalyst.

***Additional Materials** (also see Basic Protocol)*

Biotin or long-chain biotin
Dimethylformamide (DMF), amine-free
Diisopropylcarbodiimide (DIC)
Pins with completed peptides (see Basic Protocol)

1. Dissolve biotin in amine-free DMF to a concentration of 125 mM.
2. Prepare a 10× solution of DIC (activating agent) by dissolving 158 mg DIC in 1 ml DMF and prepare a 10× solution of HOBt (catalyst) by dissolving 192 mg HOBt in 1 ml DMF.
3. Activate the biotin with the 10× concentrate solutions of activation agent and catalyst (80:10:10 [v/v/v]).
4. Dispense 150 µl/well (for gears) or 450 µl/well (for macrocrowns) into reaction trays.
5. Immerse the pins with completed peptides in the reaction tray and incubate ≥2 hr.
6. Wash the pins in methanol.

The pins can now be used for side chain deprotection (see Basic Protocol, step 16).

REAGENTS AND SOLUTIONS

*Use Milli-Q water in all recipes and protocol steps. For common stock solutions, see **APPENDIX 2E**; for suppliers, see **SUPPLIERS APPENDIX**.*

Acetylation solution

For 200 ml:
193 ml dimethylformamide (DMF)
6 ml acetic anhydride
1 ml *N*-ethyldiisopropylamine
Prepare immediately before use and discard after use

DO NOT expose pins to acetic anhydride at any other time except during acetylation. Also, do not store acetic anhydride anywhere near where peptide synthesis is performed.

The DMF does not need to be amine-free.

20% piperidine/DMF

Prepare a 20% (v/v) solution of the best quality piperidine available in analytical reagent–grade dimethylformamide (DMF). Prepare a fresh solution for each synthesis (solution can be reused several times within a synthesis). Store at room temperature in an amber bottle containing activated molecular sieves to remove moisture.

CAUTION: This solution is highly flammable and toxic.

continued

BOWMAN CENTRAL UNIVERSITY LIBRARY

If high-quality piperidine is not available, it may have to be treated with solid sodium hydroxide and redistilled.

DMF need not be amine-free.

Side chain deprotecting (SCD) solution

33 parts (v/v) trifluoroacetic acid
1 part (v/v) ethanedithiol
2 parts (v/v) anisole
2 parts (v/v) thioanisole
2 parts (v/v) H_2O
Prepare immediately before use and do not store or reuse

CAUTION: This solution is corrosive and extremely malodorous. Contamination of the laboratory, especially with ethanedithiol, should be avoided. Wipe the outside of ethanedithiol-contaminated equipment or containers with dilute, 0.1% aqueous hydrogen peroxide to oxidize ethanedithiol to a nonodorous compound before removing the container from the fume hood. DO NOT allow hydrogen peroxide to contact other readily oxidizable materials or reagents.

Sonication buffer

1% (w/v) SDS
0.1 M sodium phosphate buffer, pH 7.2 (*APPENDIX 2E*)
0.1% (v/v) 2-mercaptoethanol (2-ME)
Store at room temperature up to 1 week

CAUTION: Before discarding sonication buffer, destroy remaining 2-ME by adding 2 ml 30% hydrogen peroxide per liter of buffer.

COMMENTARY

Background Information

The multipin method was developed by Dr. H.M. Geysen and coworkers (Geysen et al., 1984, 1987) as a scanning method for linear antibody-defined epitopes. Eventually in the late 1980s, the method was adapted to parallel synthesis of cleaved (soluble) peptides (Maeji et al., 1990), opening the way for systematic scanning of T helper (Reece et al., 1993) and cytotoxic epitopes (Burrows et al., 1994). Initially only suitable for synthesis of short peptides (up to 10 amino acid residues), the method can now routinely produce peptides of up to 20 residues of acceptable quality for initial screening experiments (Valerio et al., 1993).

Critical Parameters

Successful peptide synthesis requires reagents of a quality appropriate to the particular step, and the careful application of those reagents. For example, the protected amino acids need to be free of reactive counterions such as dicyclohexylamine (DCHA), contaminating unprotected amino acid, isomers such as the D-amino acid, and water. Check carefully that the amino acid as supplied is EXACTLY the same as specified in the manual or on the software. Apart from quality testing each amino acid, the best assurance of quality is to buy only from reputable suppliers.

Dimethylformamide (DMF) is the primary solvent for carrying out reactions (couplings) on pins. Its low volatility and moderate polarity make it suitable for dissolving the amino acids and solvating the graft polymer/growing peptide on the pin surface. Purity is not critical for some (washing) steps, but is critical for the DMF used just before and during amino acid coupling. Presence of excessive amine in the DMF results in loss of activated amino acid because the amino acid couples to the amine rather than to the peptide on the pin. Fortunately, the pin system allows use of substantial molar excesses of incoming amino acid (typically 6- to 1000-fold), so loss of some amino acid is not disastrous. Fresh DMF of the best available grade should be used for the coupling, and it is recommended that the amine level be tested using the FDNB test (Stewart and Young, 1984).

Liberal use is made of methanol as a washing solvent. Analytical reagent grade methanol is readily available at low cost in large containers (20 or 200 liters) and is relatively easy to dispose of. It is possible to reduce the use of methanol by reusing it for washes: the last wash

BCU IASL CENTRAL UNIVERSITY LIBRARY

bath in any series should be in fresh (pure) methanol. In the next round of washes, the former last bath is then reassigned as the second-to-last wash, the previously second-to-last bath becomes the third-to-last, and so on. For each synthesis cycle, the first wash bath in the series is the one which is discarded. The presence of methanol is undesirable during reactions on the pins, but as it evaporates readily it can be easily removed by standing the block in a moving stream of air, such as the opening of an operating chemical fume hood. Methanol will dry more rapidly and the methanol-washed pins will take up less moisture from the air if the methanol is warm (e.g., prewarmed to 45°C in a closed bottle in a water bath).

Other solvents (e.g., ether, petroleum ether, acetonitrile) should be the best available grade.

Carrying out the correct synthesis of the peptides requires that all steps are performed with a very high level of attention to detail. All cyclically repeated steps (washes and deprotections) must be performed, and the activation and dispensing of the amino acids for each coupling cycle must be carried out exactly, or the peptides made may have the incorrect sequence, may be missing an amino acid, or may be truncated. Computerized equipment is available for assisting with the accurate dispensing of amino acids to the wells in a reaction tray (e.g., "Pin-Aid," Chiron Technologies; Carter et al., 1992). The growing peptides must not be subjected to conditions that would prematurely block or deprotect the side chains (for example, from premature exposure to acetic anhydride or trifluoroacetic acid, which should be stored well away from where peptide synthesis is being performed).

As a spot test for correct completion of all the steps of synthesis, it is wise to synthesize controls on each block of 96 pins. For noncleavable peptides, these controls can be peptide sequences that can be probed with an antibody known to react with the peptide. In this case, one of the two peptides should be a negative control, such as a randomized sequence. For cleavable peptides, the quantity and quality of the controls can be monitored by the usual techniques of HPLC (*UNIT 11.6*), amino acid analysis (*UNIT 11.9*), and mass spectrometry (Chapter 16). Ultimately, proof that an assay result is a function of the particular peptide made has to rely on a confirmatory experiment carried out with more highly-characterized peptide or on analysis of a sample of the particular peptide used in the experiment.

Once peptides have been made, they need to be handled and stored carefully to prevent degradation. Noncleavable peptides (pins) should be stored dry in a refrigerator after removal of any bound protein. If stored with desiccant they should be stable for months to years. Cleaved peptides can be stored frozen or as dry powder. After a long period of storage, it is wise to reassay controls or confirm the quality of the stored peptide by analysis.

Another parameter critical to data from large numbers of peptides is to ensure that the identity of each peptide is properly tracked and that activity is not ascribed to the wrong peptide. Consistent use of the 8 × 12 microtiter plate format for synthesis, storage, assay, and use of computerized records for tracking all three processes can help avoid mistakes. Tracking and control is particularly easy if the assay data is read directly from a microtiter plate reader to a computer that is programmed with the peptide information because this method avoids manual data transcription.

Anticipated Results

For a noncleavable pin-peptide synthesis, two control peptides, one of which is reactive with a monoclonal antibody in ELISA and the other serving as a nonbinding peptide control, should show the specific binding expected based on past data. For cleaved peptides, the yield of control peptide should be in the range expected from the stated pin loading (substitution level), e.g., 1 µmol for GAP and DKP kits or 5 µmol for the MPS kit. Purity of the cleaved controls should be consistent with the results of previous batches and should be of an acceptable standard.

Testing of a systematic set of peptides in a bioassay can give data that is interpretable without recourse to additional controls, because a systematic set of peptides through a protein includes many sequences that are unlikely to be reactive sequences, i.e., they act as internal negative controls. Figure 18.2.7 shows one set of ELISA data from scanning noncleaved peptides with a monoclonal antibody. In screening for T helper cell responsiveness it is critical to include many control cultures, not only controls with no peptide added but also controls with nonstimulatory peptide. Systematic sets of peptides automatically include such controls (Reece et al., 1994).

BOSTON CENTRAL UNIVERSITY LIBRARY

Time Considerations

If amino acid coupling is carried out at 3 cycles/day, which can fit into a conventional working day, then it will take up to 2 weeks to make a set of 15-mers, as there is extra time required for side chain deprotection and drying down (depending on the peptide format). Although this may seem slow, the fact that hundreds or thousands of peptides can be made simultaneously means that a project requiring large numbers of peptides is completed in a very short time. Indeed, the rate-limiting step may be the time it takes to carry out the assays on the large number of peptides when they become available.

From this perspective, biotinylated peptides produced on glycine acid peptide (GAP), diketopiperazine (DKP), or multiple peptide syn-

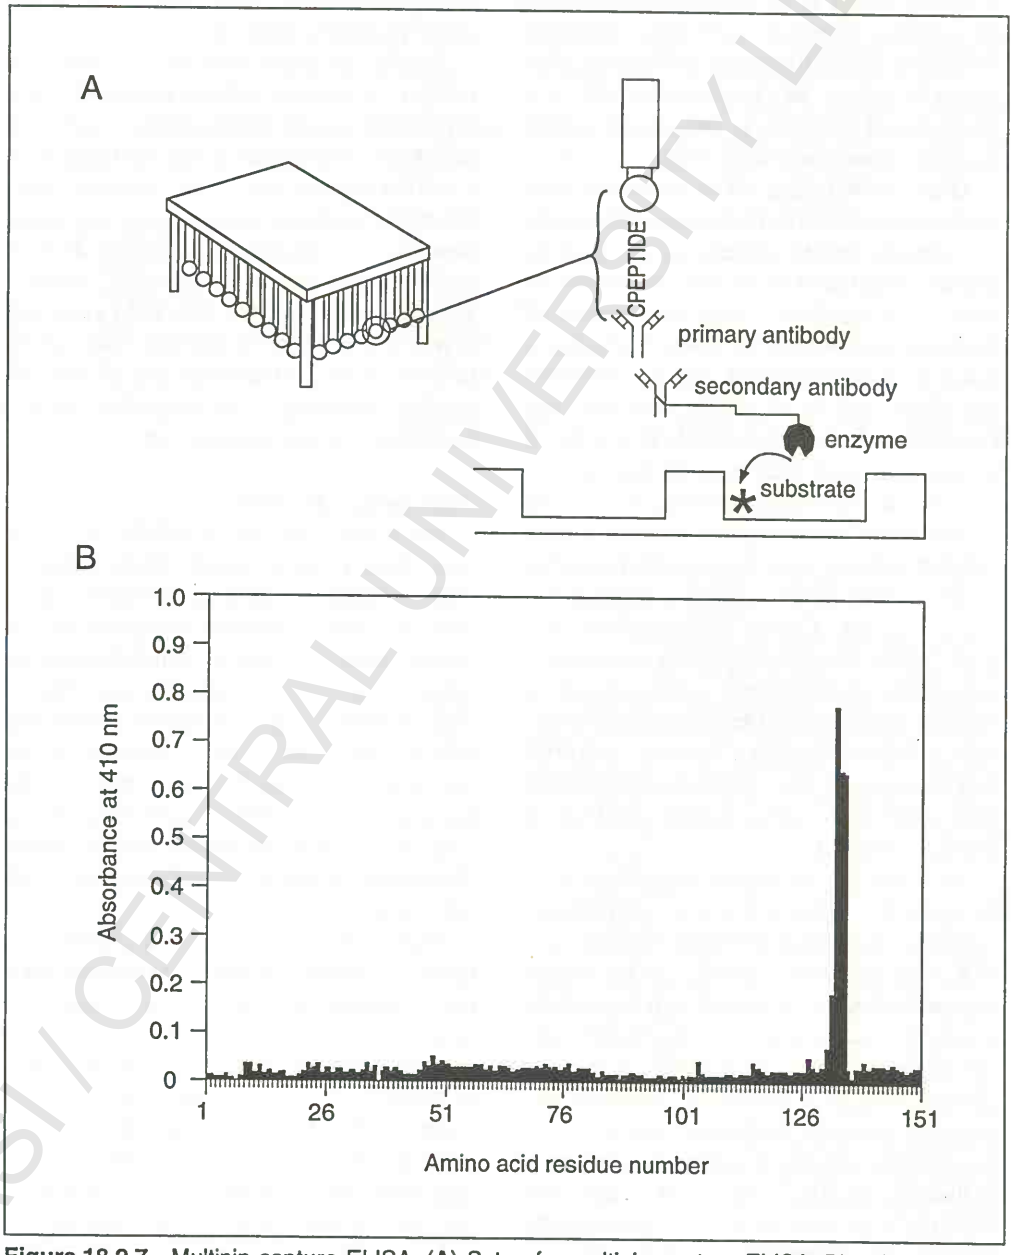

Figure 18.2.7 Multipin capture ELISA. (**A**) Setup for multipin capture ELISA. Pins (gears) with peptides covalently attached are incubated in primary antibody, secondary antibody, and substrate developer in ELISA plates. The absorbance is measured and the resulting absorbance values are graphed versus peptide number, corresponding to the N-terminal residue number of the peptide in the protein sequence. (**B**) Peptide pin capture ELISA results with a monoclonal antibody against pins bearing octamer peptides of gonococcal pilin protein. All the peptides that show high readings contain a significant portion of the epitope. (Diagram courtesy of Dr. Fred Cassels, Walter Reed Army Institute of Research, Washington, D.C.)

PCU IAST / CENTRAL UNIVERSITY LIBRARY

thesis (MPS) pins have a great advantage over the noncleavable peptide (NCP) pin-bound peptides, as the latter can only be assayed once a day, whereas hundreds of parallel assays can be carried out on all biotinylated peptides at once. Reading data directly into a computer enables the massive amounts of data to be stored efficiently for later analysis.

Dispensing amino acids can be carried out efficiently by two people, one reading out the position into which the amino acid is to be dispensed and the other doing the actual dispensing. The passive partner (reader) can also act as a cross-checker to ensure no mistakes are made. If a computer-controlled pointing device is used, accuracy is improved and dispensing becomes a one-person operation. For large syntheses (>200 peptides), it is important that the dispensing be fast and accurate so that three couplings can be carried out per day.

Synthetic Peptides for Production of Antibodies that Recognize Intact Proteins

Antibodies that recognize intact proteins can be produced through the use of synthetic peptides based on short stretches of the protein sequence, without first having to isolate the protein. The procedure for selecting stretches of protein sequence likely to be antigenic is relatively straightforward. However, no procedure will identify a single sequence guaranteed to be effective, nor will it usually identify the best single sequence to use. Rather, several sequences will be identified that have a higher-than-average probability of producing an effective antigen.

The steps to produce an effective antibody include: (1) designing the peptide sequence based on the sequence of the protein; (2) synthesizing the peptide; (3) preparing the immunogen either by coupling the synthetic peptide to a carrier protein or through the use of a multiple antigenic peptide (MAP); (4) immunizing the host animal; (5) assaying antibody titer in the host animal's serum; and (6) obtaining the antiserum and/or isolating the antibody. This unit covers steps 1 and 3; step 2 requires a laboratory with expertise in peptide synthesis. Peptide synthesis services are widely available both academically and commercially.

The best method to select potentially effective sequences is via a computer-assisted strategy (see Basic Protocol 1). An alternative manual method is also described (see Alternate Protocol 1) but is not recommended to replace the use of algorithms if there is a choice. A small synthetic peptide is usually insufficiently immunogenic on its own, and two methods have been developed to solve this problem. The first (see Basic Protocol 2) involves chemically coupling the synthetic peptide to a carrier protein to boost the immune response. The second method (see Alternate Protocol 2) entails direct synthesis of a MAP covalent multimer of the simple peptide sequence. Both methods have proven effective and it is a matter of personal preference which to use. Coupling to a carrier protein requires additional chemical manipulations after synthesis of the peptide, while the MAP is complete and ready for immunization at the conclusion of the synthetic protocol. Disadvantages of MAPs are that they are more difficult to produce homogeneously and to analyze postsynthetically. They also may be more prone to insolubility problems.

A carrier protein is a relatively large molecule capable of stimulating an immune response independently. A synthetic peptide coupled to a carrier protein acts as a hapten and produces antibodies specific for the hapten (antibodies against the carrier protein are also produced). The most commonly used carrier proteins are keyhole limpet hemocyanin (KLH) and bovine or rabbit serum albumin (BSA or RSA). KLH is usually preferred, because it tends to elicit a stronger immune response and is evolutionarily more remote from mammalian proteins. A common problem with KLH, however, has been its solubility. Pierce Chemical Company sells a preparation of KLH purported to have better solubility properties (see below).

Alternatively, peptides can be coupled to carrier proteins through either their amino (see Alternate Protocol 3) or carboxyl groups (see Alternate Protocol 4). These two alternate protocols are not recommended as a first choice for coupling, but are included because they have been used successfully and may be advantageous for certain special applications discussed in the Commentary. Also presented are methods for assaying free sulfhydryl content and for reducing disulfide bonds in synthetic peptides (see Support Protocols 1 and 2).

BOSTON CENTRAL UNIVERSITY LIBRARY

Once the coupling procedure has been performed, it is possible to determine the approximate degree of coupling by amino acid analysis. However, in most instances this is unnecessary and the product can be used directly.

BASIC PROTOCOL 1

COMPUTER-ASSISTED SELECTION OF APPROPRIATE ANTIGENIC PEPTIDE SEQUENCES

An antibody produced in response to a simple linear peptide will most likely recognize a linear epitope in a protein. Furthermore, that epitope must be solvent-exposed to be accessible to the antibody. The general features of protein structure that correspond to these criteria are turns or loop structures, which are generally found on the protein surface connecting other elements of secondary structure, and areas of high hydrophilicity, especially those containing charged residues. As a consequence, computer algorithms that predict protein hydrophilicity and tendency to form turns are very useful. Several analytic programs or algorithms that attempt to do this have been developed. Although the choice of method may rely on availability or personal preference, there tends to be a high level of agreement among them. As stated earlier, none of the methods will identify the one single sequence guaranteed to produce an effective antibody against any given protein. Rather, the methods will offer several good candidates, one or several of which can be used.

Many of these algorithms may already be available on a local computer system. They are included in many commercial software packages such as GCG (Genetics Computer Group; see *SUPPLIERS APPENDIX*). The ExPASy Web site of the University of Geneva offers free access to a variety of different programs over the Internet at *http://expasy.hcuge.ch/www/tools.html*.

The following protocol utilizes the hydropathy index developed by Kyte and Doolittle (1982) and the secondary structure prediction method for β turns developed by Chou and Fasman (1974) found in the tool "Protscale" at the ExPASy Internet address.

1. Using the selected algorithms, compute the hydropathy index and the tendency for β-turns of the protein sequence. Use a window size of 7 or 9 and give equal weight to each amino acid. Record the results in either graphical or numerical form, or both.

   As an example, the graphical representation of these results for the protein sequence shown in Figure 18.3.1 is presented in Figure 18.3.2.

   A window size determines the number of amino acids to be used in computing a value for the amino acid at the center of the window. For example, a window size of 9 includes 4

BOU IASI / CENTRAL UNIVERSITY LIBRARY

amino acids on each side of the central amino acid. The value computed for the central amino acid is the simple average of the values for each amino acid in the window.

2. Compare the results of the two analyses and look for areas of sequence that are high in turn tendency and high in hydrophilicity (low in hydrophobicity).

   In Figure 18.3.2, these areas correspond to positive peaks in the Chou-Fasman analysis and negative peaks in the Kyte-Doolittle analysis. The three best areas in terms of amplitude and correlation are shaded. These correspond to the sequences underlined in Figure 18.3.1. (Note the alignment of these peak optima as compared to the peaks around residue 300.)

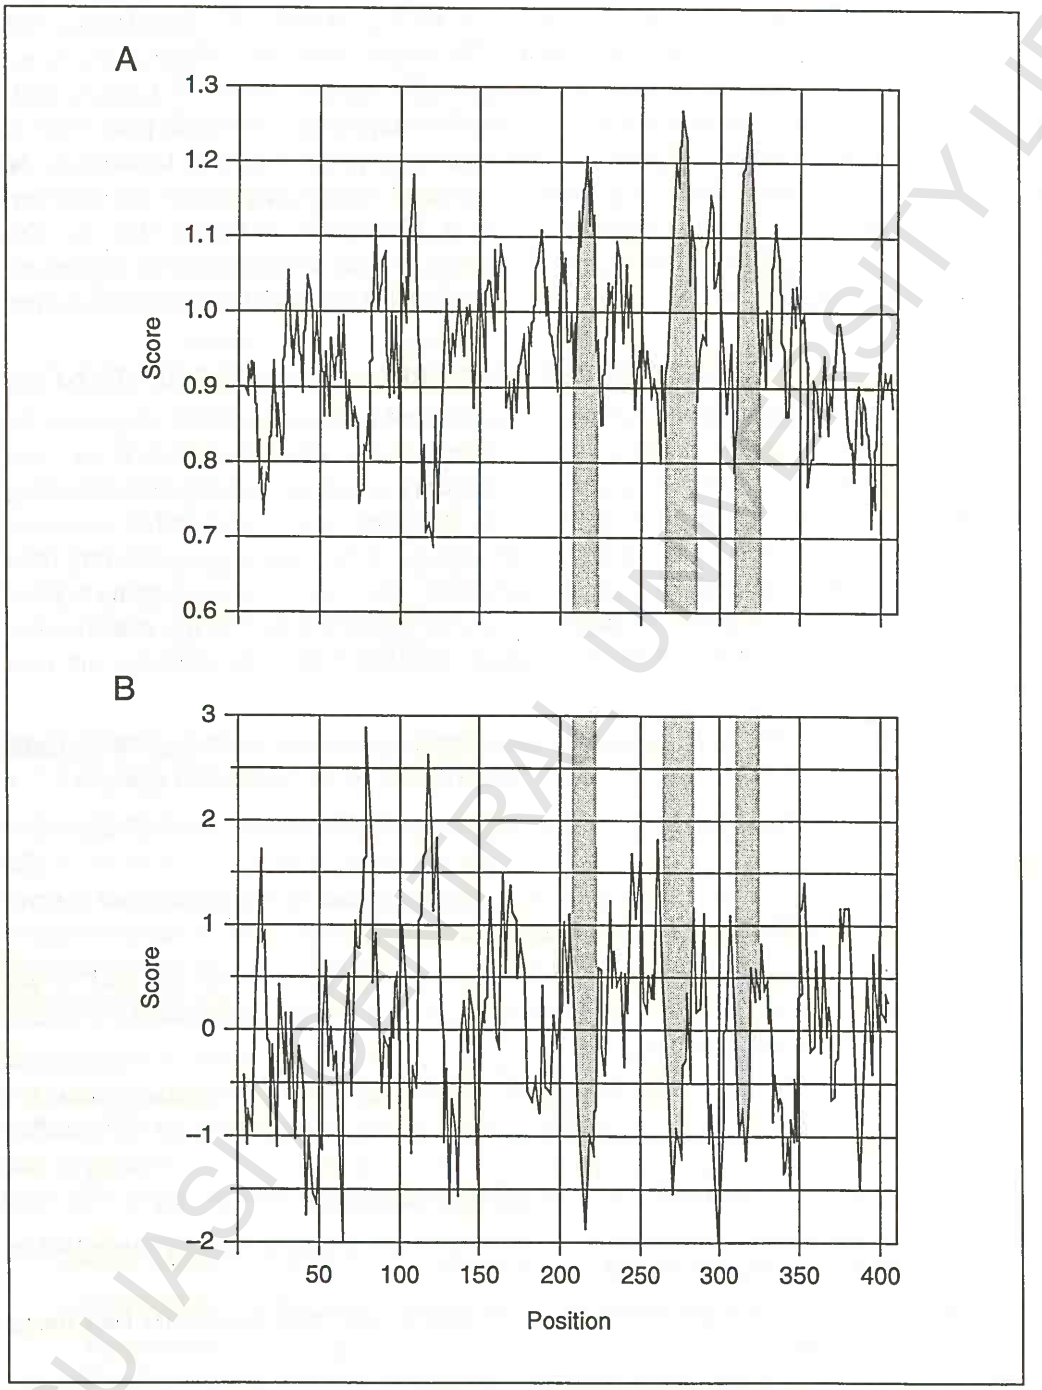

Figure 18.3.2 Graphical representation of the results generated by a computer algorithm for the sequence in Figure 18.3.1, analyzed by the method presented in Basic Protocol 1. The shaded areas represent three regions in the sequence meeting criteria for selection as potential immunogens. (**A**) Analysis for β turns (Chou and Fasman, 1974). (**B**) Analysis for hydrophobicity (Kyte and Doolittle, 1982).

RGU IASTD CENTRAL UNIVERSITY LIBRARY

3. Examine the sequences for glycosylation site motifs and discard any sequences that contain them unless it is known that the protein is not glycosylated.

   Amino acids in glycosylated regions may be shielded from presentation to an antibody by masking carbohydrates.

   Amino-linked carbohydrate chains can occur at Asn-X-Ser or Asn-X-Thr sequences. Hydroxyl-linked carbohydrate chains do not appear to have a set motif.

4. Select the best sequences resulting from this analysis to use as antigenic peptides. These are sequences where the largest positive values (peaks with positive deflection) for turn propensity correspond in position to the largest negative values (peaks with negative deflection) for hydrophobicity. The values obtained in these analyses are relative and dependent on the individual protein's composition, so it is not possible to set an arbitrary minimum value as a cutoff for rejecting a particular peak. Rather, always select the peaks of greatest magnitude in any given sequence. In addition, the immediate amino-terminal and carboxyl-terminal regions of proteins are often exposed to solvent. If these areas appear to be hydrophilic in nature, they are also acceptable candidates. Thus each analysis may provide several potential sequences. How many peptides to make (see Anticipated Results) is a matter of individual choice.

ALTERNATE PROTOCOL 1

MANUAL INSPECTION TO SELECT APPROPRIATE PEPTIDE SEQUENCES

If computer algorithms are not available, it is possible to select potential sequences by manual inspection. Although there is no evidence that a manual method is any less effective than the use of computer algorithms, there is a greater probability of overlooking potentially important areas of sequence. It is therefore recommended that computer analysis be used whenever it is available. Although it can be done, it would be very time consuming and labor intensive to manually calculate values for every overlapping peptide offset by a single amino acid in the same way that the algorithms do. For this reason, areas rich in polar residues are selected for manual calculation of hydrophilicity and turn propensity.

1. Visually inspect the protein sequence and select areas that contain at least two to three charged residues (Lys, Arg, His, Asp, Glu) within a 10- to 15-residue span.

   If this criterion cannot be met, select sequences with the greatest number of charged residues.

2. From the sequences identified in step 1, select a subset of sequences that are the highest in Ser, Thr, Asn, Gln, Pro, and Tyr content.

3. Calculate average hydrophilicity and turn propensity for each amino acid in the selected sequences using the values given in Table 18.3.1 and a window of 9 residues (see Basic Protocol 1, step 1).

   Be sure to include the residues flanking the selected sequence for calculation of values for the residues at the ends of the selected sequence. In other words, don't use different size windows.

4. Plot the values for each amino acid of a chosen sequence.

   Sequences whose optimal values for hydrophilicity and turn propensity correspond (as in Fig. 18.3.2) are considered good candidates.

5. Inspect sequences for glycosylation motifs and discard these candidates (see Basic Protocol 1, step 3).

   Amino acids of glycosylated regions may be masked in native proteins, so an antibody raised against them would be ineffective.

6. Select the best sequences (see Basic Protocol 1, step 4 for criteria), choosing a high turn-propensity-to-hydrophobicity ratio.

DESIGNING A SYNTHETIC PEPTIDE FOR COUPLING TO A CARRIER PROTEIN

BASIC PROTOCOL 2

Although there is no direct evidence to show that the state of the termini of the peptide affects its ability to produce antibodies that will react with the protein, most procedures suggest that the termini of the peptide should mimic their native state. Thus, sequences whose terminal residues normally are in peptide linkage in the protein can have their amino-terminal and carboxyl-terminal groups modified by acetylation and amidation, respectively, during synthesis.

Modification of the amino or carboxyl termini will decrease the polarity of the peptide in solution and could have a significant effect on the peptide's solubility. If the peptide lacks sufficient protonatable side chains, modification of the termini can be omitted. A general rule to predict solubility is that the total number of charges at a given pH should be at least 20% of the number of residues in the peptide.

1. Choose a sequence of 10 to 15 amino acid residues for the synthetic peptide.

   Longer peptides are more difficult and expensive to make, and they are usually unnecessary.

   Try to choose a stretch of sequence that contains some charged residues such as Arg, Lys, His, Glu, and Asp. In addition to the high likelihood of these amino acids to be located on the surface of the protein, they aid handling of the synthetic product by promoting solubility.

2a. *If the selected sequence does not contain an internal cysteine:* Place a cysteine on either the amino or carboxyl terminus for use in coupling to a carrier protein with a

BCU IAS CENTRAL UNIVERSITY LIBRARY

heterobifunctional cross-linking reagent such as MBS, *m*-maleimidobenzoyl-*N*-hydroxysuccinimide ester (see Basic Protocol 3).

Cross-linking with heterobifunctional reagents is the recommended procedure for most peptides (see Basic Protocol 3). As an alternative to using a chemical cross-linking reagent, any peptide, regardless of amino acid content, can also be photochemically linked to a carrier protein if p-benzoyl benzoic acid is added to the peptide during synthesis (see Alternate Protocol 5). Although photochemical cross-linking is effective, it is not widely used.

If the sequence includes the immediate amino or carboxyl terminal sequence of the protein, the cysteine should be placed on the end that would normally be engaged in the internal peptide bond. For sequences internal to the protein, the cysteine may be placed at either end according to the preference of the synthetic chemist. However, if amino-terminal capping (acetylation) is used after the coupling of each amino acid during synthesis, it is preferable to place the cysteine on the amino-terminal end of the peptide since then only the full-length peptide will contain the cysteine residue. In this way, if synthetic difficulties are encountered, only the full-length peptide will couple to the carrier. If placed on the carboxyl terminal end, the cysteine residue tends to racemize during synthesis unless a chlorotrityl resin is used. However, this should not have an effect on the rest of the peptide or the generation of antibodies.

2b. *If the sequence contains an internal cysteine residue:* Do not add a terminal cysteine for MBS cross-linking. Rather, use an alternative coupling procedure (see Alternate Protocols 3, 4, or 5) or synthesize a multiple antigenic peptide (MAP; see Alternate Protocol 2).

Internal cysteine sulfhydryl groups will also cross-link to the carrier protein and result in a peptide attached at multiple points. If the sulfhydryl will eventually be important for antibody recognition of the protein, the immunization may not produce effective antibodies. Furthermore, the additional constraint produced by the existence of multiple points of coupling may affect the ultimate ability of the antibody to recognize the protein.

3a. *For sequences whose terminal residues are in peptide linkage within the protein:* If the peptide is coupled using a heterobifunctional reagent such as MBS (see Basic Protocol 3), modify the amino and carboxyl ends by acetylation and amidation, respectively, during the synthetic procedure. If coupling is performed with a homobifunctional reagent that reacts with amino groups such as glutaraldehyde (see Alternate Protocol 3) or by the photochemical method (see Alternate Protocol 5), only amidate the carboxyl terminus. If coupling is performed with EDC (see Alternate Protocol 4), only acetylate the amino terminus.

3b. *For sequences that are amino or carboxyl terminal to the protein:* If the sequence is the immediate amino or carboxyl terminal sequence of the protein and the peptide will be coupled with a heterobifunctional reagent such as MBS (see Basic Protocol 3), leave the end that is not in peptide linkage (and the end that does not contain the additional cysteine residue for MBS coupling) as the free amino or carboxyl group unless it is known that they are normally blocked.

3c. *For sequences that are immediately amino terminal:* If the sequence is the immediate amino terminal sequence of the protein and the peptide will be coupled with a homobifunctional reagent that reacts with amino groups such as glutaraldehyde (see Alternate Protocol 3) or photochemically (see Alternate Protocol 5), amidate the C-terminus. If the sequence is the immediate carboxyl terminal sequence of the protein and the peptide will be coupled with glutaraldehyde (see Alternate Protocol 3) or photochemically (see Alternate Protocol 5), leave both termini free.

PDU IASI (CENTRAL UNIVERSITY) LIBRARY

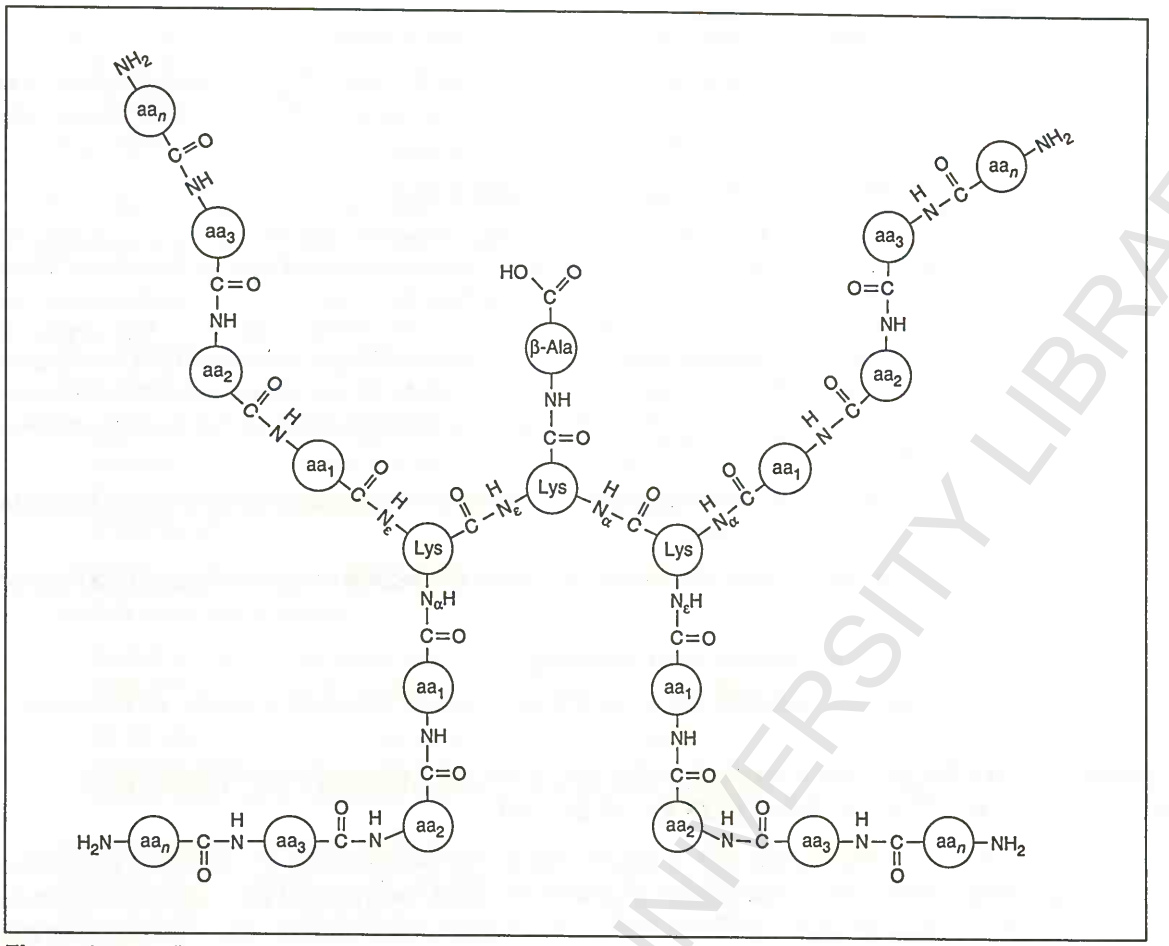

Figure 18.3.3 Representation of a four-branched multiple antigenic peptide (MAP). The MAP core is usually synthesized with a β-alanine residue attached to the solid phase support followed by a scaffold of lysine residues. The first lysine residue, attached through its α-carboxyl group to β-alanine, provides two primary amino groups (α and ε) for chain elongation. The next level of the lysine scaffold consists of two lysine residues which in turn provide four primary amino groups for chain elongation. MAPs with eight branches are formed by providing one additional layer of lysine to that depicted here.

4. If the peptide will be coupled with 1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC; see Alternate Protocol 4), block the amino terminus by acetylation.

   This should be done even if the sequence is at the immediate amino terminus of the protein, since treatment with EDC can result in the production of covalent multimers of the peptide through reaction with the N-terminal amino group. Some procedures recommend using citraconylation to temporarily protect the amino group. However, this also adds a free carboxyl group that could result in multiple site attachment of the peptide to the carrier.

DESIGNING A SYNTHETIC MULTIPLE ANTIGENIC PEPTIDE

ALTERNATE PROTOCOL 2

A multiple antigenic peptide (MAP; Posnett et al., 1988; Tam, 1988) is an effective alternative to coupling a simple linear peptide to a carrier protein. MAPs are covalent constructs consisting of a simple peptide sequence synthesized on a branched core (Fig. 18.3.3) with one copy of the peptide sequence on each of four or eight branches. One advantage of a MAP is that it is suitable for use as an immunogen at the conclusion of the synthetic process. On occasion, MAPs have produced effective protein antibodies when the conventional peptide coupled to carrier protein has not. Thus, MAPs represent an effective alternative approach for antiserum production.

BCU Main Library / CENTRAL UNIVERSITY LIBRARY

1. Select a sequence between 10 and 15 residues in length.

   Longer sequences are unnecessary and increase the probability of synthetic problems. The presence of internal cysteine residues are not a concern with MAPs, but if present, take precautions to keep them reduced.

2. Synthesize the MAPs utilizing a four-branch core.

   Synthesize the MAP core de novo, or purchase resins for solid-phase peptide synthesis with four- or eight-branched cores (available commercially from Advanced ChemTech, Novabiochem, Perkin-Elmer, AnaSpec, and Bachem Bioscience). Eight-branched cores are suitable if the peptide is no more than 12 to 14 residues and has a high degree of hydrophilicity. There are more synthetic problems with eight-branched MAPs, presumably due to the higher density of structure during synthesis: they are more difficult to characterize and probably raise a diverse antibody population against some synthetic artifacts (see Mints et al., 1997).

3. *Optional.* If the selected sequence was not the amino terminus of the protein, acetylate the new amino terminus.

   In the case of a MAP, the carboxyl terminus will remain in covalent linkage to the branched core.

4. Use the MAP directly as an immunogen.

   Coupling to a carrier protein as described in Basic Protocol 3 is usually not necessary.

BASIC PROTOCOL 3

COUPLING SYNTHETIC PEPTIDES TO A CARRIER PROTEIN USING A HETEROBIFUNCTIONAL REAGENT

If the synthetic peptide was designed with a cysteine residue at one terminus (see Basic Protocol 2, step 2a), the following procedure should be followed for coupling to keyhole limpet hemocyanin (KLH) or other carrier proteins. Care must be taken to assure that the cysteine sulfhydryl group has remained reduced. Under normal synthetic conditions, if the peptide was lyophilized and stored dry immediately after synthesis, the sulfhydryl usually remains in the reduced state. The presence of free sulfhydryl groups in the peptide can be determined with Ellman's reagent (see Support Protocol 1) just prior to use; alternatively, high-resolution mass spectrometry can be used. If reduction is needed, follow the cysteine reduction procedure (see Support Protocol 2) before starting the coupling process.

The reagent most commonly used for this purpose is *m*-maleimidobenzoyl-*N*-hydroxysuccinimide ester (MBS). However, several related reagents (all available from Pierce) offer some additional features. Sulfo-MBS (Pierce) is a water-soluble alternative to MBS. Succinimidyl 4-(*N*-maleimidomethyl)-cyclohexane-1-carboxylate (SMCC) and its sulfonated analog sulfo-SMCC provide the same chemistry with a more pH-stable maleimide (see step 1). The MBS and SMCC reagents can be used interchangeably in this protocol (the sulfo reagents can be dissolved in aqueous solution, while the others must be dissolved in an organic solvent; the concentrations listed are appropriate for all four).

Materials

Keyhole limpet hemocyanin (KLH; Pierce, Sigma, Calbiochem, or Boehringer Mannheim)
0.01 M sodium phosphate buffer, pH 7.5 (*APPENDIX 2E*)
10 mg/ml MBS in fresh *N*,*N*-dimethylformamide (DMF)
0.05 M and 0.1 M sodium phosphate buffer, pH 7.0 (*APPENDIX 2E*)
Synthetic peptide with a reduced cysteine residue at either the N- or C-terminus
6 M guanidine·HCl (see recipe)

Small glass vial with flat bottom

RGU IAS/CENTRAL UNIVERSITY LIBRARY

~0.9 × 15–cm gel filtration column with Sephadex G-25 or G-50 (Pharmacia Biotech) or Bio-Gel P2 or P4 (Bio-Rad) resin; *or* prepacked PD-10 column (Pharmacia Biotech)

Additional reagents and equipment for gel filtration chromatography (*UNIT 8.3*)

NOTE: Do not use Tris or other buffers with primary amino groups in this procedure.

CAUTION: MBS is a moisture-sensitive irritant. Read the Material Safety Data Sheet before use.

1. Dissolve 5 mg KLH in ~0.5 ml of 0.01 M sodium phosphate buffer, pH 7.5, in a small, flat-bottomed vial.

   A pH range of 7.0 to 7.5 offsets competing reactions. Although the unprotonated form of the amine reacts with the N-hydroxysuccinimide ester and would be optimal at pH >8.0, hydrolysis of the ester bond and reaction of the maleimide group with amines is enhanced at higher pH.

2. Add 100 µl of 10 mg/ml MBS/DMF solution and stir gently with a micro stir-bar 30 min at room temperature.

   A small amount of precipitate may form during this procedure and is acceptable. However, if the precipitate is large, perform the procedure again with fresh components.

   As an alternative to performing this coupling procedure from scratch, it is possible to purchase MBS-activated KLH (Pierce; Boehringer Mannheim) or kits containing MBS-activated KLH and an alternate MBS-activated protein for use in ELISA assays (Pierce).

3. Separate MBS-activated KLH from free MBS on a ~0.9 × 15–cm gel filtration column, equilibrating and eluting the column with 0.05 M sodium phosphate buffer, pH 7.0. Collect 0.5-ml fractions and read their absorbance at 280 nm (*UNIT 8.3*).

   The first peak to elute is the KLH-MBS conjugate. These fractions may appear cloudy. The second peak is uncoupled MBS.

4. Pool the KLH-MBS conjugate fractions in a separate tube.

5. Dissolve 5 mg of the synthetic peptide in 0.01 M sodium phosphate buffer, pH 7.0, immediately prior to use. If the peptide is poorly soluble, use 6 M guanidine·HCl.

   Maleimide groups react specifically with sulfhydryls at slightly acid to neutral pH.

6. Add the peptide solution to the KLH-MBS conjugate. Stir gently with a micro stir-bar 3 hr at room temperature.

   The coupling may be continued overnight.

7. Dialyze against 4 liters distilled water overnight at 4°C. Use for immunizations within 24 hr.

ASSAY OF FREE SULFHYDRYLS WITH ELLMAN'S REAGENT

SUPPORT PROTOCOL 1

Free sulfhydryl content of a peptide can be quantitatively determined with Ellman's reagent, 5,5′-dithio-bis(2-nitrobenzoic acid). The molar extinction coefficient at 412 nm of thionitrobenzoate, the colored species generated when the reagent reacts with a free thiol, is 14,150 in 0.1 M sodium phosphate buffer (see Fig. 18.3.4). The sensitivity of the reaction is in the low nmol/ml range for sulfhydryl groups, making it well suited for synthetic peptides. By dry weight most synthetic peptides are only ~60% to 75% peptide, the remainder consisting of counterions and water of hydration. Amino acid analysis (see *UNIT 11.9*) is needed to establish the actual peptide content unambiguously, but such precise measurement is not usually necessary for qualitative evaluation of the free sulfhydryl content of a peptide sample.

(**A**) Cross-linking with MBS; (**B**) cross-linking with glutaraldehyde; (**C**) cross-linking with EDC; (**D**) reaction of free sulfhydryls with Ellman's reagent to produce a colorimetric product; (**E**) reduction of disulfides with DTT. Abbreviations: KLH, keyhole limpet hemocyanin; MBS, *m*-maleimidobenzoyl-*N*-hydroxysuccinimide ester; EDC, 1-ethyl-3-(3-dimethylamino-propyl) carbodiimide; DTT, *N,N*-dithiothreitol.

EDU IASI CENTRAL UNIVERSITY LIBRARY

Materials

Cysteine standard stock solution (see recipe)
0.1 M sodium phosphate, pH 8.0 (*APPENDIX 2E*)
Peptide to be assayed
Ellman's reagent solution (see recipe)
13 × 100–mm glass test tubes

1. Prepare a cysteine standard curve by adding 25 µl, 50 µl, 100 µl, 150 µl, 200 µl, and 250 µl of cysteine standard stock solution to separate 13 × 100–mm tubes. Add ≤250 µl of each peptide to be tested to separate tubes. Bring the volume in each tube to 250 µl with 0.1 M sodium phosphate, pH 8.0. Add 250 µl of 0.1 M sodium phosphate, pH 8.0, to a blank tube.

   The cysteine content of the peptide to be assayed should fall within the range of the standard curve (37.5 to 375 nmol).

2. Add 50 µl Ellman's reagent solution and 2.5 ml of 0.1 M sodium phosphate, pH 8.0, to each tube. Mix and incubate 15 min at room temperature.
3. Measure absorbance at 412 nm (A_{412}).
4. Plot the A_{412} values of the standards after subtracting the value for the blank to produce a standard curve. Use this curve to determine the free sulfhydryl content of the peptides.

REDUCING CYSTEINE GROUPS IN PEPTIDES

SUPPORT PROTOCOL 2

When a peptide is synthesized with a terminal cysteine residue to be used for coupling with MBS (see Basic Protocol 3), the cysteine must be in the reduced state (present as free -SH rather than as a disulfide) in order to participate in the reaction with the coupling reagent. If peptides are lyophilized immediately after extraction from the resin cleavage cocktail or reversed-phase HPLC and used immediately after reconstitution, oxidation of cysteine side chains is usually not a problem. However, if oxidation to disulfides has occurred, the peptide can be reduced prior to use with the protocol presented here.

Dithiothreitol (DTT) is preferred to 2-mercaptoethanol (2-ME) as a reducing agent because its lower redox potential allows it to be effective at lower concentrations, and the reaction goes to completion because formation of the six-membered ring containing an internal disulfide is energetically favorable (see Fig. 18.3.4; also see *APPENDIX 3A*).

To determine if reduction is necessary, quantitate the level of free sulfhydryl groups with Ellman's reagent (see Support Protocol 1).

Materials

Synthetic peptide
0.1 M sodium phosphate, pH 8.0 (*APPENDIX 2E*)
1 M aqueous dithiothreitol (DTT)
1 N HCl

100- or 250-µl polypropylene tubes
Nitrogen gas source

Additional reagents and equipment for reversed-phase HPLC of peptides (see *UNIT 11.6*)

BCU IAS / CENTRAL UNIVERSITY LIBRARY

1. Dissolve 5 to 10 mg of peptide in 0.1 M sodium phosphate, pH 8.0.
2. Add 100 µl of 1 M DTT.
3. Flush nitrogen over the surface of the liquid, seal the tube, and incubate 1 hr at 37°C.
4. Acidify with 1 N HCl and desalt by reversed-phase HPLC (*UNIT 11.6*).
5. Pool peptide fractions and lyophilize. Store lyophilized at 4°C until ready to use (up to several days).

   The oxidation state of the peptide can usually be followed by analytical monitoring of its elution position on reversed-phase HPLC. Disulfide-linked dimers of peptides generally elute later than the monomeric peptide.

ALTERNATE PROTOCOL 3

COUPLING SYNTHETIC PEPTIDES TO A CARRIER PROTEIN USING A HOMOBIFUNCTIONAL REAGENT

The available homobifunctional reagents couple compounds through primary amino groups. Therefore, peptides with internal lysine residues should not be used in this procedure. The reagent most commonly used for this procedure is glutaraldehyde, but it should not be used with peptides containing internal Cys, Tyr, or His residues. Other homobifunctional cross-linking reagents that can be used in the same way as glutaraldehyde, but do not cross react with Cys, Tyr, or His residues, are also available: disuccinimidyl suberate (DSS), disuccinimidyl glutarate (DSG), and bis (sulfosuccinimidyl) suberate (BS3; all available from Pierce). However, these reagents are not widely employed for coupling peptides to proteins and are not considered the method of choice, and methods for their use have not been formalized. This is probably because coupling of the synthetic peptide to itself and aggregation of the carrier protein can occur with homobifunctional reagents such as these. Glutaraldehyde, on the other hand, although also subject to this limitation, has generally been used successfully.

Additional Materials (also see Basic Protocol 3)

50 mM sodium borate buffer, pH 8.0 (pH adjusted with HCl)
Glutaraldehyde solution (see recipe)
1 M glycine in 50 mM sodium borate buffer, pH 8.0

NOTE: Do not use Tris or other buffers with primary amino groups in this procedure.

1. Dissolve 5 mg KLH in ~1.0 ml of 50 mM sodium borate buffer, pH 8.0.
2. Add 5 mg synthetic peptide.
3. Slowly add 1 ml fresh glutaraldehyde solution with gentle mixing at room temperature. Allow to react for an additional 2 hr with gentle mixing.

   Formation of a yellowish color or milkiness is normal and does not affect the sample.

4. Add 0.25 ml of 1 M glycine to bind unreacted glutaraldehyde.

   A darker yellow to brown color may develop.

5. Dialyze the reaction mixture overnight at 4°C against 4 liters of 50 mM sodium borate buffer, pH 8.0, and then overnight against water. Use immediately.

PSU IASI / CENTRAL UNIVERSITY LIBRARY

COUPLING SYNTHETIC PEPTIDES TO A CARRIER PROTEIN USING A CARBODIIMIDE

ALTERNATE PROTOCOL 4

This procedure couples amino groups to carboxyl groups by way of activation of the carboxyl group with a water-soluble carbodiimide. Since the procedure is most easily performed in one step, peptides containing internal Asp, Glu, Lys, Tyr, or Cys residues should not be used. Also, in order to avoid making polymers of the peptide, the amino terminus should be blocked by acetylation during synthesis (see Basic Protocol 2). While this method has been used successfully, it is not considered to be the method of choice except in special situations.

Additional Materials (also see Basic Protocol 3)

1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC; Pierce), used fresh or stored desiccated and frozen
0.1 N HCl

NOTE: Buffers containing amino or carboxyl groups should not be used in this procedure. According to some reports, buffers containing phosphate groups should also be avoided. Water is the safest choice as a solvent.

1. Dissolve 5 mg synthetic peptide in 1 ml water.
2. Add 25 mg EDC and carefully adjust pH to 4.0 to 5.0 by adding small amounts of 0.1 N HCl. Allow to react for 5 to 10 min at room temperature with gentle mixing.

   pH paper suffices to monitor this adjustment.
3. Dissolve 5 mg KLH in 0.5 ml water and add to solution from step 2. React 2 hr at room temperature with gentle mixing.
4. Dialyze against 4 liters of water overnight at 4°C. Use immediately.

COUPLING SYNTHETIC PEPTIDES TO A CARRIER PROTEIN PHOTOCHEMICALLY

ALTERNATE PROTOCOL 5

Most synthetic peptides today are made with 9-fluorenylmethyloxycarbonyl (Fmoc) chemistry (see Fig. 18.1.1), and therefore the following protocol links the photoactive group to the free amino terminus of the peptide. An alternative approach if *t*-butyloxycarbonyl (Boc) chemistry is used is to link it to an ε-amino group of a terminal lysine (Gorka et al., 1989).

Additional Materials (see also Basic Protocol 3)

4-benzoyl benzoic acid (Sigma or Aldrich)
Quartz spectrophotometry cuvettes

1. Have the synthetic chemist who is making the peptide attach a benzoyl benzoic acid group to the amino terminus simply by treating the reagent as the terminal residue during normal synthesis.

   This blocks the amino terminus.
2. Dissolve 5 mg KLH in ~0.5 ml of 0.01 M sodium phosphate buffer, pH 7.5.
3. Add 2 mg of synthetic peptide containing the benzoyl benzoate adduct.
4. Place in a 1-cm quartz cuvette and irradiate with 366-nm light for 3 hr at a distance of 0.5 cm. Use immediately.

   The peptide can be used directly for immunization.

BOSTON / CENTRAL UNIVERSITY LIBRARY

REAGENTS AND SOLUTIONS

Use Milli-Q-purified water or equivalent for the preparation of all buffers. For common stock solutions, see APPENDIX 2E; for suppliers, see SUPPLIERS APPENDIX.

Cysteine standard stock solution

Dissolve 26.3 mg cysteine hydrochloride monohydrate in 100 ml of 0.1 M sodium phosphate, pH 8.0 (*APPENDIX 2E*). Prepare immediately before use.

Ellman's reagent solution

Dissolve 4 mg Ellman's reagent, 5,5′-dithio-bis-(2-nitrobenzoic acid) (Pierce), in 1 ml of 0.1 M sodium phosphate, pH 8.0. Prepare immediately before use.

Glutaraldehyde solution, 0.15%

Add 30 ml of 25% aqueous glutaraldehyde solution to 5 ml of 50 mM sodium borate buffer, pH 8.0 (pH adjusted with HCl). Prepare fresh and use immediately. If the glutaraldehyde precipitates, check the pH. It should not be above 8.0; a slightly lower pH can be used (pH 7 to 8).

CAUTION: *Glutaraldehyde is a sensitizing agent that should be handled in a hood and only according to the recommendations in the Material Safety Data Sheet. When mixing solutions or performing reactions, keep the container covered to prevent vapors from escaping into the atmosphere.*

Guanidine·HCl, 6 M

Dissolve 1 g guanidine·HCl in 1 ml of 0.05 M sodium phosphate, pH 7.0. Store up to several weeks at room temperature.

The resulting 1.8-ml solution should be ~0.025 M phosphate/6 M guanidine·HCl at pH 7.0.

COMMENTARY

Background Information

Synthetic peptides are linear arrays of amino acids that in most instances possess a random structure in solution. While it is not difficult to produce antipeptide antibodies, it does not necessarily follow that the antibodies will recognize a protein containing the same stretch of sequence found in the peptide. In order for this to occur, the amino acids in the protein must be oriented to the antibody in a way similar to that of the synthetic peptide. This generally requires three basic features of the protein: (1) that the stretch of sequence be exposed to solvent; (2) that the sequence be a continuous stretch of amino acids; and (3) that it not possess a higher-order structure that renders it unrecognizable by the antibody population.

The large number of model protein structures now available indicate that almost all of the ionized groups in water-soluble proteins are on the protein surface. Asp, Glu, Lys, and Arg residues, on the average, comprise 27% of the protein surface and only ~4% of the protein interior. The fraction of residues at least 95% buried range from 0.36 to 0.60 for nonpolar residues and 0.01 to 0.23 for polar residues. Only 1% of Arg and 3% of Lys residues fall into the 95% buried range (Creighton, 1993). Therefore, it is reasonable to expect solvent-exposed areas of proteins to display relatively high levels of polar and charged residues, particularly Arg and Lys.

Proteins display three kinds of secondary structure: α-helices, β-sheets, and turns or loops (see *UNIT 17.1*). Turns or loops generally connect elements of α-helices and β-sheets, and can either fit one of several rather strict motifs with recognizable hydrogen bonding patterns or be of a more extended, random nature. These turn or loop structures appear to be most useful for antibody production because they tend to be found on the surface of proteins connecting larger arrays of helices and sheets, and they consist of continuous stretches of amino acids. Although many amino acid residues in helices and sheets are also exposed at the surface, the regular geometry of amino acids contained within them makes them less suitable for this purpose. For instance, in β-sheet structures the side chain of each successive amino acid in the β-sheet strand points in the opposite direction to the ones immediately preceding and following it. Thus, even if the amino acid side chains are not predominantly buried in the interior of

BOU IASRI CENTRAL UNIVERSITY LIBRARY

the protein, only every other side chain is exposed on the same surface of the sheet. This can hinder recognition by an antibody produced with a linear peptide capable of assuming a more random structure. A similar situation exists for α-helices. Although the change in direction of the side chains of successive amino acids is perhaps not as abrupt as in β-sheets, only approximately every third or fourth side chain is found on the same surface of the helix. Epitopes in proteins have been identified in amphipathic helices, but unless the synthetic peptide assumes a similar helical structure in solution, recognition by the antibody may be problematic.

These considerations have led to more useful methods for predicting sequences that will produce antibodies recognizing intact proteins. A variety of different indices that predict hydrophilicity or hydrophobicity and secondary structure are available (see *UNITS 2.2 & 2.3*, respectively). In addition, predictive methods based on segmental mobility, side chain accessibility, and sequence variability (see Van Regenmortel et al., 1988) have also been proposed. All of these methods generally tend to yield similar results, but it must be noted that these procedures were developed for (and work best with) water-soluble proteins composed of a single globular structure. Additional complications can arise with multisubunit proteins, where normally exposed structures may be shielded by subunit interactions, or membrane proteins with large sections shielded from the solvent.

The method presented in this unit utilizes the correlation between the hydrophilic character of a peptide sequence (Kyte and Doolittle, 1982) and its propensity to form β-turn structures (Chou and Fasman, 1974). Free access to these and many other algorithms is provided at the ExPASy Web site of the University of Geneva at *http://expasy.hcuge.ch/www/tools.html*.

After selection of the peptide sequence, an effective immunogen is generally produced by coupling the peptide to a carrier protein or by synthesizing a multiple antigenic peptide (MAP), with four or eight identical peptides assembled simultaneously on the α and ε amines of the terminal lysines of a branched core (see Fig. 18.3.3).

Critical Parameters

Analyzing protein sequences with algorithms or tables of assigned values for amino acids is a well-established procedure, but evaluating these results and selecting the candidate sequences requires some consideration. To take full advantage of the results, choose areas of sequence that give the maximum values for the properties being evaluated and that also show the highest degree of residue-by-residue correlation. In other words, choose areas of maximum amplitude where the centers of the peaks correspond to the same sequence with a divergence of no more than two to three residues. Examples of this are given in Figure 18.3.2, which shows results from the method presented in Basic Protocol 1 for the sequence shown in Figure 18.3.1. The top panel in Figure 18.3.2 predicts β-turns as calculated by the method of Chou and Fasman (1974). The bottom panel is a prediction of hydrophobicity using the parameters of Kyte and Doolittle (1982). The data are analyzed by looking for areas of high turn propensity (maximum positive deflection in the top panel) and high hydrophilicity (maximum negative deflection in the bottom panel). The shaded areas in Figure 18.3.2 designate three segments that meet these criteria. Note that the maximum and minimum values of these three stretches of protein sequence correlate very well. Additional areas of high hydrophilicity (bottom panel) are found near residues 64, 132, 137, 149, and 345, although the β-turn values of these secondary candidates are not as high as those of the three shaded areas. Two equally hydrophilic areas at residues 49 and 299 correspond to downward deflections in the β-turn profile and are thus not good candidates based on this analysis.

Many different chemistries are available for coupling synthetic peptides to carrier proteins to produce effective immunogens (Van Regenmortel et al., 1988). In many cases, however, side reactions or incompatibilities in chemistry between the coupling agent and the residues present in the peptide can be problematic. In order to simplify the process and present the greatest probability of success in most cases, only a few coupling methods are presented in this unit. In this regard, the recommended coupling procedure is cross-linking of the peptide via cysteine residues to keyhole limpet hemocyanin (KLH) with the heterobifunctional reagent *m*-maleimidobenzoyl-*N*-hydroxysuccinimide ester (MBS; see Basic Protocol 3). This effective method has enjoyed great success and can be used for virtually any peptide. The one caveat is that it is not recommended for peptides with internal cysteine residues, since they will also link to the carrier. It is also critical, when coupling with MBS through an added terminal

BOSTON UNIVERSITY MEDICAL LIBRARY

cysteine residue, that the sulfhydryl group of the peptide be present in the free or reduced form (see Support Protocols 1 and 2).

In addition to MBS coupling, other procedures commonly used (see Alternate Protocols 3 and 4) are included as alternatives for use in special situations, but these are not recommended as a general alternative to MBS because they are more restrictive and have the potential for undesirable side reactions. Glutaraldehyde coupling (see Alternate Protocol 3) should not be used with peptides containing internal Lys, Cys, Tyr, or His residues and, since it is a homobifunctional reagent, cross-linking of the peptide to itself and the carrier to itself can occur. The latter lowers antigenicity and can result in extensive aggregation and precipitation of the carrier. 1-ethyl-3(3-dimethylaminopropyl) carbodiimide (EDC; see Alternate Protocol 4) is a water-soluble carbodiimide and should not be used with peptides containing internal Lys, Glu, Asp, Tyr, or Cys residues. Alternate Protocol 5 describes a simple photochemical coupling strategy (Gorka et al., 1989).

Another good alternative for most peptides is the production of a multiple antigenic peptide (MAP; see Alternate Protocol 2). With this method the composition of the peptide is not a concern beyond its potential solubility properties. In most cases, since hydrophilic sequences are selected, this also is not a major problem. Both four- and eight-branched MAPs have been found to be effective. However, four-branched MAPs are recommended because they are less prone to synthesis problems and are easier to characterize.

As with any synthetic peptide, the product must be well characterized before use. If the peptide is not what it was intended to be, this decreases the probability of generating antibodies that will recognize the protein. At the very least, check synthetic peptides for homogeneity by analytical HPLC and correct mass by mass spectrometry (see Chapter 16). Characterization of MAP can be more problematic due to their multibranched nature (Mints et al., 1997): HPLC and mass spectrometric analysis can be compromised by the presence of four to eight peptide chains per molecule, each of which may have only a small percentage of modification at any particular residue but which in the aggregate contribute to broad spectra. However, this feature of MAPs usually does not tend to compromise their ability to form antigens of the proper peptide since the correct sequence is usually present in high enough concentration that a significant amount of specific antibody is produced among the polyclonal population. Amino acid analysis (*UNIT 11.9*), which is less sensitive to multiple small differences, tends to give a reasonable assessment of the MAP integrity.

Anticipated Results

The methods outlined in this unit produce an effective polyclonal antiserum against an intact protein from a single peptide sequence ~50% to 70% of the time. Therefore, it is advisable to prepare two or three different peptides from a given protein to increase the probability of at least one of them being effective.

Time Considerations

Computer-assisted analysis of a protein sequence and inspection of the data to select several candidate sequences takes from 5 to 30 min. Manual analysis of a protein sequence can take several hours but can certainly be accomplished in <1 day. Selection of peptide design and manner of synthesis as well as selection of a coupling method will take <1 hr. Actual preparation of the peptide can be accomplished in 3 to 4 days, but this may vary depending on the turnaround time of the synthetic laboratory. Coupling a synthetic peptide to a carrier protein takes from 1 to 2 days. Although not covered in this unit, production of the antisera will vary with the animal and protocol used, but generally requires 2 to 3 months. It is therefore advisable to inject several animals with different peptides at one time.

Characteristics of Amino Acids

The physical properties of the amino acids determine the structure and function of the proteins in which they are found. Some useful details and relevant physical characteristics of the amino acids can be found in Table A.1A.1. Information about modified amino acids is provided in Table A.1A.2. The chemical structures of the amino acids, and an explanation of the role these structures play in enzymes, can be found in Figure A.1A.1. The three-dimensional structure of proteins is largely determined by the packing of their hydrophobic cores; the properties of amino acids that govern this packing are their relative hydrophobicities, which are discussed in *UNIT 2.2*, and their shapes and volumes, which can be assessed by referring to the space-filling models shown in Figure A.1A.2.

Post-translational modifications will change the mass of a protein or peptide; values for some common mass changes are listed in Table A.1A.3. The changes in mass resulting from modification of proteins with different carbohydrates are shown in Table A.1A.4.

Table A.1A.1 Compositions and Masses of the Twenty Commonly Occurring Amino Acid Residues[a,b]

Name	Composition	Monoisotopic mass	Average mass	pK_a of ionizing side chain[c]	Occurrence in proteins (%)
Alanine (Ala, A)	C_3H_5NO	71.03711	71.0788	—	8.3
Arginine (Arg, R)	$C_6H_{12}N_4O$	156.10111	156.1876	~11.5–12.5 (12)	5.7
Asparagine (Asn, N)	$C_4H_6N_2O_2$	114.04293	114.1039	—	4.4
Aspartic acid (Asp, D)	$C_4H_5NO_3$	115.02694	115.0886	3.9–4.5 (4)	5.3
Cysteine (Cys, C)	C_3H_5NOS	103.00919	103.1448	8.3–9.5 (9)	1.7
Glutamic acid (Glu, E)	$C_5H_7NO_3$	129.04259	129.1155	4.3–4.5 (4.5)	6.2
Glutamine (Gln, Q)	$C_5H_8N_2O_2$	128.05858	128.1308	—	4.0
Glycine (Gly, G)	C_2H_3NO	57.02146	57.0520	—	7.2
Histidine (His, H)	$C_6H_7N_3O$	137.05891	137.1412	6.0–7.0 (6.3)	2.2
Isoleucine (Ile, I)	$C_6H_{11}NO$	113.08406	113.1595	—	5.2
Leucine (Leu, L)	$C_6H_{11}NO$	113.08406	113.1595	—	9.0
Lysine (Lys, K)	$C_6H_{12}N_2O$	128.09496	128.1742	10.4–11.1 (10.4)	5.7
Methionine (Met, M)	C_5H_9NOS	131.04049	131.1986	—	2.4
Phenylalanine (Phe, F)	C_9H_9NO	147.06841	147.1766	—	3.9
Proline (Pro, P)	C_5H_7NO	97.05276	97.1167	—	5.1
Serine (Ser, S)	$C_3H_5NO_2$	87.03203	87.0782	—	6.9
Threonine (Thr, T)	$C_4H_7NO_2$	101.04768	101.1051	—	5.8
Tryptophan (Trp, W)	$C_{11}H_{10}N_2O$	186.07931	186.2133	—	1.3
Tyrosine (Tyr, Y)	$C_9H_9NO_2$	163.06333	163.1760	9.7–10.1 (10.0)	3.2
Valine (Val, V)	C_5H_9NO	99.06841	99.1326	—	6.6

[a]For corresponding structures, see Figure A.1A.1 and Figure A.1A.2.

[b]The molecular mass of a normally terminated and unmodified peptide or protein may be calculated by summing the masses of the appropriate amino acid residues and adding the masses of H and OH for the N and C termini, respectively. In cases where cysteines are linked to form disulfide bridges, the mass of two hydrogen atoms should be subtracted for each disulfide bridge in the molecule. Specifically, monoisotopic masses were calculated using the atomic masses of the most abundant isotope of the elements: C = 12.0000000, H = 1.0078250, N = 14.0030740, O = 15.9949146, and S = 31.9720718. Average masses were calculated using the atomic weights of the elements: C = 12.011, H = 1.00794, N = 14.00674, O = 15.9994, and S = 32.066.

[c]These values are included for anyone wishing to make approximate isoelectric point determinations based on protein composition. Values for the terminal residues depend on the identity of the residue: α-amino, pK_a 6.8–8.2 (8.0); α-carboxyl, pK_a 3.2–4.3 (3.6). Values in parentheses are based on those given by Matthew et al. (1978) and provide a good starting point for determinations.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Table A.1A.2 Compositions and Masses of Unusual and Modified Amino Acid Residues[a]

Name	Composition	Monoisotopic mass	Average mass
Carboxymethylcysteine (Cme)	$C_5H_7NO_3S$	161.01466	161.1815
Carboxyamidomethyl cysteine (Cam)	$C_5H_8N_2O_2S$	160.030650	160.195940
Pyridylethylcysteine (PECys)	$C_{10}H_{12}N_2OS$	208.06703	208.23239
Acrylamide-modified cysteine (AACys)	$C_6H_{10}N_2O_2S$	174.04631	174.22363
Cysteic acid [Cys(O_3H)]	$C_3H_5NO_4S$	150.99393	151.1430
Dehydroalanine (Dha)	C_3H_3NO	69.02146	69.0630
4-Carboxyglutamic acid (Gla)	C_4H_5NO	173.03242	173.1253
Homoserine (Hse)	$C_4H_7NO_2$	101.04768	101.1051
Hydroxylysine (Hyl)	$C_6H_{12}N_2O_2$	144.08988	144.1736
Hydroxyproline (Hyp)	$C_5H_7NO_2$	113.04768	113.1161
Isovaline (Iva)	C_5H_9NO	99.06841	99.1326
Norleucine (Nlc)	$C_6H_{11}NO$	113.08406	113.1595
Ornithine (Orn)	$C_5H_{10}N_2O$	114.07931	114.1473
Pyroglutamic acid (Pyr)	$C_5H_5NO_2$	111.03203	111.1002
Sarcosine (Sar)	C_3H_5NO	71.03711	71.0788

[a]Monoisotopic masses were calculated using the atomic masses of the most abundant isotope of the elements: C = 12.0000000, H = 1.0078250, N = 14.0030740, O = 15.9949146, and S = 31.9720718. Average masses were calculated using the atomic weights of the elements: C = 12.011, H = 1.00794, N = 14.00674, O = 15.9994, and S = 32.066.

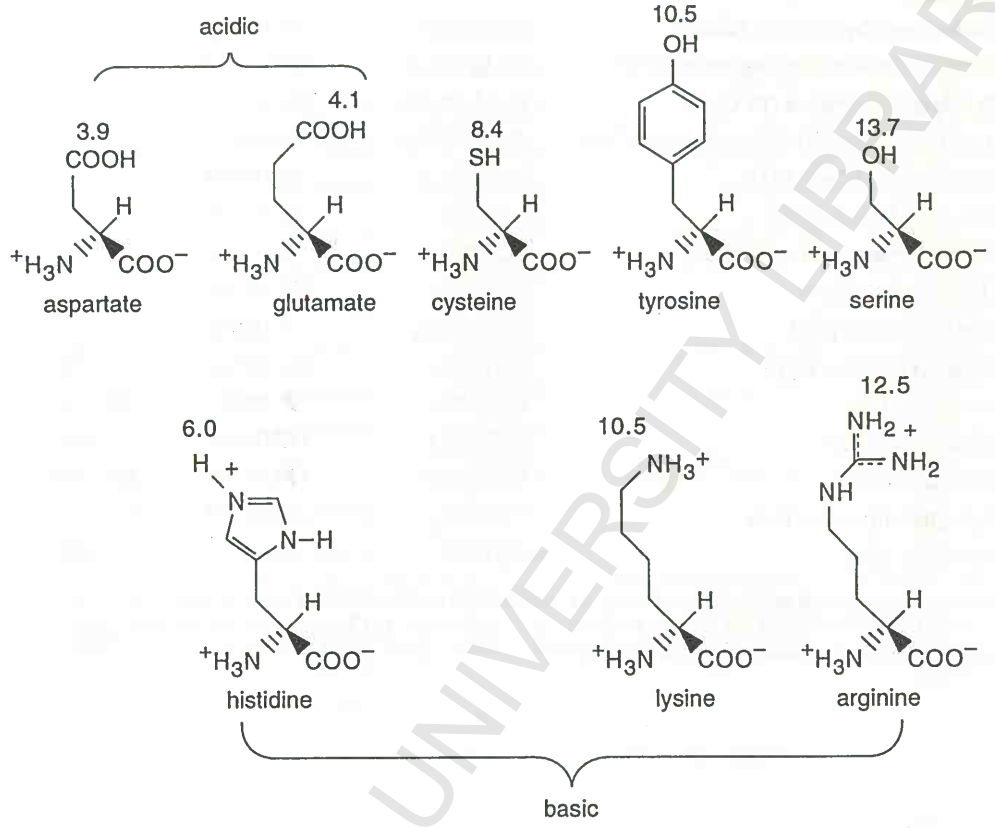
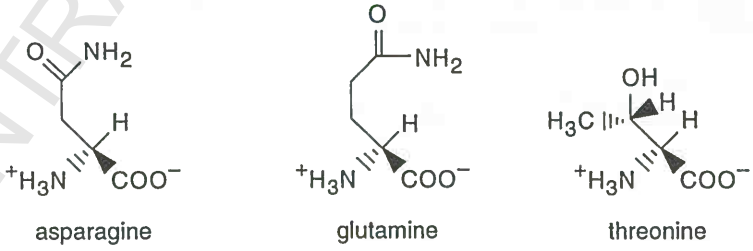
A

Amino acids with dissociable protons



Other amino acids with polar side chains



ECU IASI / CENTRAL UNIVERSITY LIBRARY

B

Nonpolar amino acids

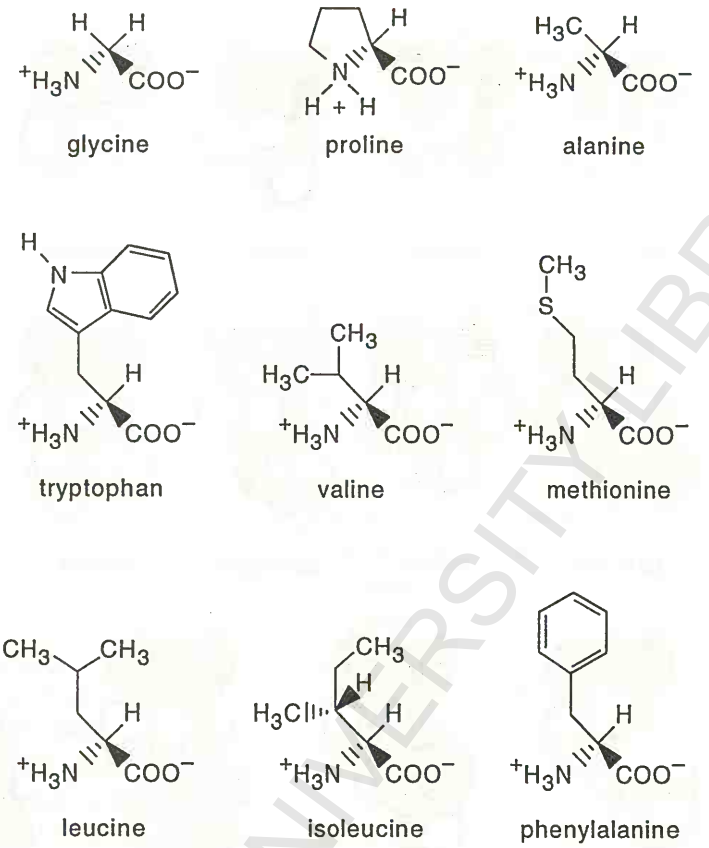


Figure A.1A.1 Line drawings of the amino acids. The amino acids are roughly divided into three groups: amino acids with dissociable protons (**A**), other amino acids with polar side chains (**A**), and nonpolar amino acids (**B**). These groupings are designed to facilitate an understanding of enzymology and the thermodynamics of protein folding.

In this representation, hydrogens are omitted except in showing ionization or stereochemistry. In the case of arginine the delocalized positive charge is indicated by dashed double bonds. At stereocenters, bold lines indicate a group is coming out of the page toward the viewer, while hashed lines indicate that the group goes into the page away from the viewer.

Amino acids with dissociable protons are generally intimately involved in the chemistry of enzymes. Acidic and basic groups can form salt bridges to substrates or to each other. They can also act as proton donors/acceptors in mechanisms that rely on acid/base catalysis. The polar side chains of some of these amino acids (notably cysteine, serine, and histidine) can act as nucleophiles. The pK_a values for the free amino acids are shown, but these values can markedly change when these groups are buried in proteins. The pK_as of the α-amino groups range from 8.7 to 10.7, while the pK_as of the α-carboxylates range from 1.8 to 2.4 (see Table A.1A.1).

Amino acids with polar side chains (**A**) can form hydrogen bonds to substrates or to each other. Cysteine, serine, and tyrosine could also be included in this group, as the ionized forms of these amino acids do not generally perform structural roles in proteins. In general, these amino acids (and the amino acids with dissociable protons) will be found on the surfaces of proteins. Cysteine is an exception, since it is slightly hydrophobic and can often be buried as a disulfide bond.

The nonpolar amino acids (**B**) are often found in the interiors of proteins or in hydrophobic substrate-binding pockets. They interact with one another like jigsaw pieces, forming tight-fitting associations that have a density similar to that of an amino acid crystal. Proline is buried less frequently than might be expected because of its predominance in turns, which are often found on the periphery of a protein.

Table A.1A.3 Mass Changes Due to Some Post-Translational Modifications of Peptides and Proteins[a]

Modification[b]	Monoisotopic mass change	Average mass change
Common modifications		
Pyroglutamic acid formation from Gln	−17.0265	−17.0306
Disulfide bond (cystine) formation	−2.0157	−2.0159
C-terminal amide formation from Gly	−0.9840	−0.9847
Deamidation of Asn and Gln	−0.9840	−0.9847
Methylation	14.0157	14.0269
Hydroxylation	15.9949	15.9994
Oxidation of Met	15.9949	15.9994
Proteolysis of a single peptide bond	18.0106	18.0153
Formylation	27.9949	28.0104
Acetylation	42.0106	42.0373
Carboxylation of Asp and Glu	43.9898	44.0098
Phosphorylation	79.9663	79.9799
Sulfation	79.9568	80.0642
Cysteinylation	119.0041	119.1442
Glycosylation with pentoses (Ara, Rib, Xyl)	132.0423	132.1161
Glycosylation with deoxyhexoses (Fuc, Rha)	146.0579	146.1430
Glycosylation with hexosamines (GalN, GlcN)	161.0688	161.1577
Glycosylation with hexoses (Fru, Gal, Glc, Man)	162.0528	162.1424
Modification with lipoic acid (amide bond to lysine)	188.0330	188.3147
Glycosylation with *N*-acetylhexosamines (GalNAc, GlcNAc)	203.0794	203.1950
Farnesylation	204.1878	204.3556
Myristoylation	210.1984	210.3598
Biotinylation (amide bond to lysine)	226.0776	226.2994
Modification with pyridoxal phosphate (Schiff base to lysine)	231.0297	231.1449
Palmitoylation	238.2297	238.4136
Stearoylation	266.2610	266.4674
Geranylgeranlylation	272.2504	272.4741
Glycosylation with *N*-acetylneuraminic acid (sialic acid, NeuAc, NANA, SA)	291.0954	291.2579
Glutathionylation	305.0682	305.3117
Glycosylation with *N*-glycolylneuraminic acid (NeuGe)	307.0903	307.2573
5′-Adenosylation	329.0525	329.2091
Modification with 4′-Phosphopantetheine	339.0780	339.3294
ADP-ribosylation (from NAD)	541.0611	541.3052
Adventitious modifications		
Acrylamide	71.0371	71.0788
Glutathione	304.0712	304.3038
2-Mercaptoethanol	75.9983	76.1192

[a]To obtain the molecular mass of a modified peptide or protein, the appropriate mass changes should be algebraically added to the molecular mass calculated for the unmodified molecule.

[b]A more extensive list of modifications is available from the Delta mass site at http://www.medstv.unimelb.edu.au/WWWDOCS/SVIMRDocs/MassSpec/deltamassV2.html.

Biantennary (1 dHex; 0 NeuAc)	1768.640	884.3	589.5	1769.643	884.8	589.9
Triantennary (1 dHex; 0 NeuAc)	2133.772	1066.9	711.3	2134.982	1067.5	711.7
Tetraantennary (1 dHex; 0 NeuAc)	2498.904	1249.5	833.0	2500.321	1250.2	833.4

[a]End-group mass (+18.011 for monoisotopic, +18.015 for chemical average) + in-chain mass = molecular mass of carbohydrate. Determined M_r of peptide (attachment site = Asn) – in-chain mass of carbohydrate.

[b]Abbreviations: dHex, deoxyhexose; Hex, hexose; HexN, hexosamine; HexNAc, *N*-acetylhexosamine; NeuAc, *N*-acetylneuraminic acid.

ECU IASI / CENTRAL UNIVERSITY LIBRARY

Commonly Used Detergents

Detergents are polar lipids that are soluble in water. The presence of both a hydrophobic and hydrophilic portion makes these compounds very useful for lysis of lipid membranes, solubilization of antigens, and washing of immune complexes.

TYPES OF DETERGENTS

A large variety of detergents are available (Helenius et al., 1979). For biochemical studies, they are usually categorized according to the type of hydrophilic group they contain—anionic, cationic, amphoteric, or nonionic. Tables A.1B.1 and A.1B.2 list commonly used members of each type. In general, nonionic and amphoteric detergents are less denaturing for proteins than ionic detergents. Sodium cholate and sodium deoxycholate are the least denaturing of the commonly used ionic detergents.

Two properties of detergents are important in their consideration for biological studies: the critical micelle concentration (CMC) and the micelle molecular weight (Table A.1B.1). The CMC is the concentration at which monomers of detergent molecules combine to form micelles; each detergent micelle has a characteristic micelle molecular weight. Detergents with a high micelle molecular weight, such as nonionic detergents, are difficult to remove from samples by dialysis. The CMC and the micelle molecular weight will vary depending on the buffer, salt concentration, pH, and temperature. In general, adding salt will lower the CMC and raise the micelle size.

Table A.1B.1 Physical Properties of Commonly Used Detergents[a,b]

Detergent	mp (°C)	Molecular weight (Da)		CMC	
		Monomer	Micelle	% (w/v)	M
Anionic

[c] Denaturing refers to disruption of secondary and tertiary protein structure.

[d]Ionic detergents are unsuitable for ion-exchange chromatography (*UNIT 8.2*).

CHOICE OF DETERGENTS

Ionic detergents are very good solubilizing agents, but they tend to denature proteins by destroying native three-dimensional structures. This denaturing ability is useful for SDS-PAGE (*UNIT 10.1*), but is detrimental where native structure is important, as when functional activities must be retained (antibody activity is usually retained in <0.1% SDS). Nonionic and mildly ionic detergents are less denaturing and can often be used to solubilize membrane proteins while retaining protein-protein interactions. The following detergent properties are detrimental in certain procedures:

1. Phenol-containing detergents (e.g., Triton X-100 and NP-40) have a high absorbance at 280 nm and hence interfere with protein monitoring during chromatography (most ionic detergents do not absorb at 280 nm; Brij- and Lubrol-series detergents are nonionic detergents that do not have substantial absorbance at 280 nm). Phenol-containing detergents also induce precipitation in the Folin protein assay (but they can be used with the Bradford protein assay; *UNIT 3.4*). Finally, they are readily iodinated and so should not be present during radioiodination.

2. Many detergents have a very high micelle molecular weight (Table A.1B.1), which makes their use in gel filtration impossible since protein sizes are insignificant relative to the micelle size. In addition, such detergents cannot be readily removed by dialysis.

3. Sodium cholate and sodium deoxycholate are insoluble below pH 7.5 or above an ionic strength of 0.1%. SDS will often crystallize below 20°C.

4. Ionic detergents interfere with nondenaturing electrophoresis (*UNIT 10.3*) and isoelectric focusing (*UNIT 10.2*).

RCU IASI IDENTITAL UNIVERSITY LIBRARY

Detergents can be removed or exchanged for other detergents by a variety of procedures (Hjelmeland, 1979; Furth et al., 1984; Harlow and Lane, 1988). Ionic and amphoteric detergents can usually be removed by dialysis *UNIT 4.4*. Pierce makes Extracti-Gel D for removing a variety of detergents from protein solutions (*Pierce Immunotechnology Catalog* and *Handbook on Protein Modification*).

Conversion Factors and Half-Life Information for Radioactivity

Discussion of radioactivity may use different terms for measurements of radioactivity and dose. Conversion factors for these terms are presented in Table A.1C.1. In addition, when investigators are working with a particular radiolabeled compound, it is necessary to calculate the amount of remaining radioactivity based on the amount of time that has elapsed from the reference date and the half life of the radioisotope (see Fig. A.1C.1). Decay factors for the commonly used shorter half life radioisotopes are presented in Table A.1C.2. For information about working with radioisotopes, see Guide for Safe Handling of Radioisotopes (*APPENDIX 2B*).

Table A.1C.1 Conversion Factors for Radioactivity

Measurement of Radioactivity

The SI unit for measurement of radioactivity is the Becquerel:

1 Becquerel (Bq) = 1 disintegration per second

The more commonly encountered unit is the Curie (Ci):

$1\ Ci = 3.7 \times 10^{10}\ Bq$

$= 2.22 \times 10^{12}$ disintegrations per minute (dpm)

1 millicurie (mCi) = 3.7×10^{7} Bq = 2.22×10^{9} dpm

1 microcurie (μCi) = 3.7×10^{4} Bq = 2.22×10^{6} dpm

Conversion factors:

1 day = 1.44×10^{3} min = 8.64×10^{4} sec

1 year = 5.26×10^{5} min = 3.16×10^{7} sec

counts per minute (cpm) = dpm × (counting efficiency)

Measurement of Dose

The SI unit for energy absorbed from radiation is the Gray (Gy):

1 Gy = 1 joule/kg

Older units of absorbed energy are the rad and Roentgen (R):

1 rad = 100 ergs/g = 10^{-2} Gy

1 R = 0.877 r in air = 0.93 – 0.98 r in water and tissue

The SI unit for radiation dosage is the Sievert (Sv), which takes into account the empirically determined relative biological effectiveness (RBE) of a given form of radiation:

dosage [Sv] = RBE × dosage [Gy]

$$RBE = \frac{\text{(biological effect of a dose of standard radiation [Gy])}}{\text{(biological effect of a dose of other radiation [Gy])}}$$

RBE = 1 for commonly encountered radionuclides

The older unit for dosage is the rem (Roentgen-equivalent-man):

1 rem = 0.01 Sv

Table A.1C.2 Decay factors for calculating the amount of radioactivity present at a given time after a reference date. For example, a vial containing 1.85 MBq (50 μCi) of an ^{35}S-labeled compound on the reference date will have the following activity 33 days later: $1.85 \times 0.770 = 1.42$ MBq; $50 \times 0.770 = 38.5$ μCi.

LABORATORY GUIDELINES, EQUIPMENT, AND STOCK SOLUTIONS

Laboratory Safety

Persons carrying out the protocols in this manual may encounter the following hazardous or potentially hazardous materials (1) pathogenic and infectious biological agents and (2) toxic chemicals and carcinogenic, mutagenic, or teratogenic reagents (Table A.2A.1). Most governments regulate the use of these materials; it is essential that they be used in strict accordance with local and national regulations. Cautionary notes are included in many instances throughout the manual, and some specific guidelines are provided below (and in references therein). However, we emphasize that users must proceed with the prudence and precautions associated with good laboratory practice, under the supervision of personnel responsible for implementing laboratory safety programs at their institutions. Guidelines for the safe use of radioisotopes are presented in *APPENDIX 2B*.

SAFE USE OF BIOHAZARDS AND INFECTIOUS BIOLOGICAL AGENTS

Precautions described in this section should be applied to the routine handling of viable pathogenic microorganisms, as well as all human-derived materials, because they may harbor dangerous pathogens such as human immunodeficiency virus (HIV), hepatitis B virus (HBV), cytomegalovirus (CMV), Epstein-Barr virus (EBV), and a host of bacterial pathogens. In addition to the guidelines provided herein, experimenters can find a wealth of information about handling infectious agents in the government publications *Biosafety in Microbiological and Biomedical Laboratories* and *Working Safely with HIV in the Research Laboratory* (see Literature Cited).

Routine Precautions When Working with Biohazards

The following practices are recommended for all laboratories handling potentially dangerous microorganisms, whether pathogenic or not:

1. Decontaminate all work surfaces after each working day using an appropriate disinfectant. Decontaminate all spills of viable material. See discussion under Disinfectants for Biohazards.
2. Decontaminate all liquid or solid wastes that have come in contact with viable material.
3. Do not pipet by mouth.
4. Do not allow eating, drinking, smoking, or application of cosmetics in the work area. Do not store food in refrigerators that contain laboratory supplies.
5. Wash hands with disinfectant soap or detergent after handling viable materials and before leaving the lab. Do not handle telephones, doorknobs, or other common utensils without disinfecting hands.
6. When handling viable materials, minimize creation of aerosols.
7. Wear lab coats (preferably disposable) when in work area, but do not wear them away from the work area.
8. Wear disposable latex gloves when handling viable materials. These should be disposed of as biohazardous waste. Change gloves if they are directly contaminated.

Current Protocols in Protein Science (1996) A.2A.1-A.2A.26
Copyright © 1996 by John Wiley & Sons, Inc.

BOWIE STATE UNIVERSITY LIBRARY

9. Control pest populations. Windows in the lab that can be opened must be equipped with screens to exclude insects.
10. Use furniture that is easy to clean—i.e., with smooth, waterproof surfaces and as few seams as possible.
11. Keep biohazard waste in covered containers free from leaks. Use orange bags or red bags as required by institutional procedure (see discussion under Disposal of Biohazards). Autoclave and dump hazardous waste without undue delay.

Disinfectants for Biohazards

Major laboratory suppliers sell disinfectants based on quaternary ammonium compounds that are acceptable for routine biohazard decontamination (see *SUPPLIERS APPENDIX*). These include Roccal (Baxter), Vesphene II (Fisher), and industrial disinfectants such as concentrated Lysol. 10% chlorine bleach may also be used for decontamination. An antimicrobial liquid soap (e.g., Vionex; Fisher) should be provided in a dispenser near the sink so that no one need handle the outside of the container to use it.

Disposal of Biohazards

Most institutions have defined procedures for disposal of biohazardous waste, but the following are common to all of these systems:

1. All contaminated material should be placed in autoclavable bags, which should be contained in a plastic trash pail or wire frame. If large numbers of disposable pipets or other pointed instruments are being used, it may be necessary to double-bag the material. Autoclavable biohazard bags are sold by all major laboratory supply houses. In some institutions it is necessary to color code the biohazard waste (e.g., orange bags for less dangerous waste and red ones for suspected HIV-containing material). All of these bags are marked with the universal biohazard symbol.
2. At time of disposal, the bags are loosely closed (not completely sealed) with temperature-sensitive autoclave tape (also widely available from supply houses), placed in an autoclavable basin, and sterilized at 121°C. When the tape indicates that sterilization temperature has been achieved, it is then possible to dispose of the waste by ordinary means.
3. At many institutions, contaminated hypodermic needles, scalpels, broken glass, and other sharp objects must be disposed of separately. These must be placed in appropriate "sharps" containers (e.g., Baxter), which may be autoclaved when full.

SAFE USE OF HAZARDOUS CHEMICALS

It is not possible in the space available to list all the precautions required for handling hazardous chemicals. Many texts have been written about laboratory safety (see Literature Cited and Key References). Obviously, all national and local laws should be obeyed, as well as all institutional regulations. Controlled substances are regulated by the Drug Enforcement Administration. By law, Material Safety Data Sheets must be readily available. All laboratories should have a Chemical Hygiene Plan (29CFR Part 1910.1450); institutional safety officers should be consulted as to its implementation. Help is (or should be) available from your institutional Safety Office. Use it.

Chemicals should be stored properly in compliance with regulations established by local fire departments for storage of chemicals. For example, flammable chemicals (e.g., ethanol, methanol, acetone, methyl ethyl ketone, petroleum distillates, toluene, benzene, and other materials labeled flammable) should be stored in approved flammable storage

BCU IASI CENTRAL UNIVERSITY LIBRARY

cabinets; flammable chemicals requiring refrigeration should be stored in explosion-proof refrigerators. Oxidizers should be segregated from other chemicals, and corrosive acids (e.g., sulfuric, hydrochloric, nitric, perchloric, and hydrofluoric acids) should also be stored in a separate cabinet, well-removed from the flammable organics.

Facilities should be appropriate for the handling of hazardous chemicals. In particular, hazardous chemicals should be handled only in chemical fume hoods, not in laminar flow cabinets. The functioning of the fume hoods should be checked periodically. Laboratories should also be equipped with safety showers and eye-wash facilities. Again, this equipment should be tested periodically to ensure that it functions correctly. Other safety equipment may be required depending on the nature of the materials being handled. In addition, researchers should be trained in the proper procedures for handling hazardous chemicals as well as other laboratory operations: e.g., handling of compressed gases, use of cryogenic liquids, operation of high-voltage power supplies, and operation of autoclaves.

Before starting work, a plan for dealing with spills or accidents should be in place; coming up with a good plan on the spur of the moment is very difficult. For example, have appropriate decontaminating or neutralizing agents prepared and close at hand (e.g., keep a bucket containing >1 kg of sodium or calcium carbonate handy to neutralize spills of corrosive acids). Small spills can probably be cleaned up by the researcher. In the case of larger spills, the area should be evacuated and help should be sought from those experienced and equipped for dealing with spills, e.g., the institutional Safety Office.

Protective equipment should include, at a minimum, eye protection, a lab coat, and gloves. In certain circumstances other items of protective equipment may be necessary (e.g., a face shield). Different types of gloves exhibit different chemical resistance properties; a listing of the properties of gloves is available (Forsberg et al., 1989). Gloves should, however, be regarded as the last line of defense and should be changed if they become contaminated, because many types of chemicals pass relatively freely through rubber. If possible, handling procedures should be designed so the gloves do not become contaminated. All common-sense precautions should be observed: e.g., do not pipet by mouth, keep unauthorized persons away from hazardous chemicals, do not eat or drink in the lab, wear proper clothing in the lab—sandals, open-toed shoes, and shorts are not appropriate.

Order hazardous chemicals only in quantities that are likely to used in a reasonable time. Buying large quantities at a lower unit cost is no bargain if someone (perhaps you) has to pay to dispose of surplus quantities. Substitute alcohol-filled thermometers for mercury-filled thermometers, which are a hazardous chemical spill waiting to happen.

Although any number of chemicals commonly used in laboratories are toxic if used improperly, there are a number of reagents whose toxic properties require special mention. Chemicals that exhibit carcinogenic, corrosive, flammable, lachrymatory, mutagenic, oxidizing, teratogenic, toxic, or other hazardous properties are listed in Table A.2A.1. Chemicals listed as carcinogenic range from those accepted by expert review groups as causing cancer in humans to those for which only minimal evidence of carcinogenicity exists. No effort has been made to differentiate the carcinogenic potential of the compounds in Table A.2A.1. Oxidizers may react violently with oxidizable material, e.g., hydrocarbons, wood, and cellulose. Before using any of these chemicals, thoroughly investigate all of its characteristics. Material Safety Data Sheets are readily available; they list some hazards but vary widely in quality. A number of texts describing hazardous properties are listed in Literature Cited. In particular *Sax's Dangerous Properties of Industrial Materials*, 8th ed. (Lewis, 1992) and the *Handbook of Reactive Chemical Hazards*, 5th ed. (Urben, 1995) give comprehensive listings of known hazardous properties. However, these texts list only the known properties. Many chemicals have been tested

BOSTON CENTRAL UNIVERSITY LIBRARY

Table A.2A.1 Hazardous Chemicals Commonly Used in Laboratories[a]

Chemical	Hazards[b]	Remarks[c]
Acetic acid, glacial	Corrosive, flammable liquid	
Acetonitrile	Flammable liquid, teratogenic, toxic	
Acridine orange	Carcinogenic, mutagenic	
Acrylamide	Carcinogenic, toxic	Use dust mask; polyacrylamide gels contain residual acrylamide monomer and should be handled with gloves; acrylamide may polymerize with violence on melting at 86°C
Ammoniacal silver solution	Potentially explosive	Prepare fresh solution daily; discard promptly with water or in accordance with local regulations
Ammonium hydroxide, concentrated	Corrosive, lachrymatory, toxic	
Benzidine (BDB)	Carcinogenic, toxic	See Basic Protocol 1
Bisacrylamide	Toxic	
Brilliant blue R	Carcinogenic, mutagenic	
Cetylpyridinium chloride (CPC)	Toxic	
Cetyltrimethylammonium bromide (CTAB)	Corrosive, teratogenic, toxic	
Chloroform	Carcinogenic, teratogenic, toxic	
Chlorotrimethylsilane	Carcinogenic, corrosive, flammable liquid, toxic	Reacts violently with water; see Basic Protocol 2
Chromic/sulfuric acid cleaning solution	Carcinogenic, corrosive, oxidizer, toxic	
Congo red	Mutagenic, teratogenic	
Coomassie brilliant blue G	Mutagenic	
Cresyl violet acetate	Mutagenic	
Cyanides (e.g., KCN, NaCN)	Toxic	Contact with acid will liberate HCN gas; see Basic Protocol 3
Cyanogen bromide (CNBr)	Toxic	See Basic Protocol 3
2′-Deoxycoformycin (dCF, pentostatin)	Teratogenic, toxic	
Diaminobenzidine (DAB)	Carcinogenic	See Basic Protocol 1
1,4-Diazabicyclo[2,2,2]-octane (DABCO)	Toxic	Forms an explosive complex with hydrogen peroxide
Dichloroacetic acid (DCA)	Carcinogenic, corrosive, toxic	
Dichloromethane	Carcinogenic, mutagenic, teratogenic, toxic	
Diethylamine (DEA)	Corrosive, flammable liquid, toxic	
Diethylpyrocarbonate (DEPC)	Carcinogenic, toxic	

continued

RCU IASI CENTRAL UNIVERSITY LIBRARY

Table A.2A.1 Hazardous Chemicals Commonly Used in Laboratories[a], continued

Chemical	Hazards[b]	Remarks[c]
Diethyl sulfate	Carcinogenic, teratogenic, toxic	
Diisopropyl fluorophosphate (DFP)	Neurotoxic, volatile, mutagenic	Can be diluted in aqueous solutions up to ~10 mM; inactivate by adding 1 N NaOH so that pH is ≥12; see Basic Protocol 4
Dimethyldichlorosilane	Corrosive, flammable liquid, toxic	See Basic Protocol 2
Dimethyl sulfate (DMS)	Carcinogenic, toxic	
Diphenylamine (DPA)	Teratogenic, toxic	
2,5-Diphenyloxazole (PPO)	Toxic	
Dithiothreitol (DTT)	Toxic	
Erythrosin B	Carcinogenic, mutagenic	
Ether	Flammable liquid, toxic	May form explosive peroxides on standing; do not dry with NaOH or KOH
Ethidium bromide (EtBr)	Mutagenic, toxic	See Basic Protocol 5
Ethyl methanesulfonate (EMS)	Carcinogenic, toxic	
Fluoroorotic acid (FOA)	Toxic	
Formaldehyde	Carcinogenic, flammable liquid, teratogenic, toxic	
Formamide	Teratogenic, toxic	
Formic acid	Corrosive, toxic	May explode when heated to >180°C in a sealed tube
Glutaraldehyde	Corrosive, teratogenic, toxic	
Guanidinium thiocyanate	Toxic	
Hydrazine	Carcinogenic, corrosive, toxic	May explode on distillation or react violently with traces of metal compounds or oxidizers; see Basic Protocol 6
Hydrochloric acid, concentrated	Corrosive, teratogenic, toxic	
Hydrogen peroxide (30%)	Carcinogenic, corrosive, mutagenic, oxidizer	Should not be brought into contact with organic materials, which may form explosive peroxides; may decompose violently in contact with metals, salts, or oxidizable materials; see Basic Protocol 7
Hydroxylamine	Corrosive, flammable, mutagenic, toxic	Explodes in air at >70°C
3-β-Indoleacrylic acid (IAA)	Carcinogenic	
Iodine	Corrosive, toxic	See Basic Protocol 8
Iodoacetamide	Carcinogenic, mutagenic, toxic	
Lead compounds	Carcinogenic, toxic	
2-Mercaptoethanol (2-ME)	Stench, toxic	
Mercury compounds	Teratogenic, toxic	See Basic Protocol 9

continued

BOGAZICI UNIVERSITY CENTRAL LIBRARY

Table A.2A.1 Hazardous Chemicals Commonly Used in Laboratories[a], continued

Chemical	Hazards[b]	Remarks[c]
Methionine sulfoximine (MSX)	Teratogenic, toxic	
Methotrexate (amethopterin)	Carcinogenic, mutagenic, teratogenic, toxic	
Methylene blue	Mutagenic, toxic	
Methyl methanesulfonate (MMS)	Carcinogenic, toxic	
Mycophenolic acid (MPA)	Teratogenic, toxic	
Neutral red	Mutagenic	
Nitric acid, concentrated	Corrosive, oxidizer, teratogenic, toxic	
Nitroblue tetrazolium (NBT)	Toxic	
Paraformaldehyde	Toxic	
Phenol	Carcinogenic, corrosive, teratogenic, toxic	Readily absorbed through the skin
Phenylmethylsulfonyl fluoride (PMSF)	Corrosive, toxic	Degrade by adding 1 M NaOH stats pH is ≥12; see Basic Protocol 10
Piperidine	Flammable liquid, teratogenic, toxic	
Potassium hydroxide, concentrated	Corrosive, toxic	Adding the solid to water produces a highly exothermic reaction
Propane sultone	Carcinogenic, toxic	
Propidium iodide (PI)	Mutagenic	See Basic Protocol 5
Pyridine	Flammable liquid, toxic	
Seleno-L-methionine	Highly toxic	
Sodium azide	Carcinogenic, toxic	Adding acid liberates explosive volatile, toxic hydrazoic acid; can form explosive heavy metal azides, e.g., with plumbing fixtures—*do not* discharge down drain; see Basic Protocol 11
Sodium deoxycholate (Na-DOC)	Carcinogenic, teratogenic, toxic	
Sodium hydroxide, concentrated	Corrosive, toxic	Adding the solid to water produces highly exothermic reaction
Sodium nitrite	Carcinogenic	
Sulfuric acid, concentrated	Corrosive, oxidizer, teratogenic, toxic	Dissolving concentrated sulfuric acid in water produces a highly exothermic reaction—always add concentrated sulfuric acid to water, never water to the acid
Tetramethylammonium chloride (TMAC)	Toxic	
N,N,N′,N′-Tetramethyl-ethylenediamine (TEMED)	Corrosive, flammable liquid, toxic	
Toluene	Flammable liquid, teratogenic, toxic	
Trichloroacetic acid (TCA)	Carcinogenic, corrosive, teratogenic, toxic	

continued

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Chemical	Hazards[b]	Remarks[c]
Triethanolamine acetate (TEA)	Carcinogenic, toxic	
Trifluoroacetic acid (TFA)	Corrosive, toxic	
Trimethyl phosphate (TMP)	Carcinogenic, mutagenic, teratogenic	May explode on distillation
Trypan blue	Carcinogenic, mutagenic, teratogenic	
Xylenes	Flammable liquid, teratogenic, toxic	

[a]For extensive information on the hazards of these and other chemicals as well as cautionary details, see Bretherick (1986), Furr (1990), Lewis (1992), Lunn and Sansone (1994a), Urben (1995), and Budavari (1996).

[b]Teratogenic chemicals cause developmental malformations; lachrymatory chemicals cause tearing.

only partially or not at all. Prudence dictates that, unless there is good reason for believing otherwise, all chemicals should be regarded as volatile, highly toxic, flammable human carcinogens and should be handled with great care.

Waste should always be disposed of in accordance with all applicable regulations. Waste should be segregated according to institutional requirements, for example, into solid, aqueous, nonchlorinated organic, and chlorinated organic material. Extensive information and cautionary details along with techniques for the disposal of chemicals in laboratories have been published (Bretherick, 1986; Furr, 1990; Aldrich Chemical Co., 1994; Lunn and Sansone, 1994a; Budavari, 1996). Some commonly used disposal procedures are outlined in Basic Protocols 1 to 11. Incorporation of these procedures into laboratory protocols can help to minimize waste disposal problems. Alternate Protocols 1 to 11 describe decontamination methods for some of the chemicals. Support Protocols 1 to 8 describe analytical techniques that are used to verify that reagents have been decontaminated; with modification, these assays may be used to determine the concentration of a particular chemical.

Disposal Methods

A number of procedures for the disposal of hazardous chemicals are available; protocols for the disposal and decontamination of some hazardous chemicals commonly encountered in laboratories are described in this appendix (see Table A.2A.2). These procedures are necessarily brief; for full details consult the original references or a recent collection of these procedures (see Lunn and Sansone, 1994a).

CAUTION: These disposal methods should only be carried out in a chemical fume hood by workers equipped with eye protection, a lab coat, and gloves. Additional protective equipment may be necessary.

Disposal of Benzidine and Diaminobenzidine

BASIC PROTOCOL 1

Benzidine and diaminobenzidine can be degraded by oxidation with potassium permanganate (Castegnaro et al., 1985; Lunn and Sansone, 1991a). This protocol presents a method for decontamination of benzidine and diaminobenzidine in bulk. This method can also be adapted to the decontamination of benzidine and diaminobenzidine spills (see Alternate Protocol 1). These compounds can also be removed from solution using horseradish peroxidase in the presence of hydrogen peroxide (see Alternate Protocol 2).

BOSTON UNIVERSITY LIBRARY

Table A.2A.2 Protocols for Disposal of Some Hazardous Chemicals

Protocol	Disposal method for
Basic Protocol 1	Benzidine and diaminobenzidine
Alternate Protocol 1	Spills of benzidine and diaminobenzidine
Alternate Protocol 2	Aqueous solutions of benzidine and diaminobenzidine
Support Protocol 1	Analysis for benzidine and diaminobenzidine
Basic Protocol 2	Silanes
Basic Protocol 3	Cyanide and cyanogen bromide
Support Protocol 2	Analysis for cyanide
Basic Protocol 4	Diisopropyl fluorophosphate in buffer or water
Alternate Protocol 3	Diisopropyl fluorophosphate in *N,N*-dimethylformamide
Alternate Protocol 4	Bulk quantities of diisopropyl fluorophosphate
Support Protocol 3	Spills of diisofluorophosphate
Basic Protocol 5	Ethidium bromide and propidium iodide
Alternate Protocol 5	Equipment contaminated with ethidium bromide
Alternate Protocol 6	Ethidium bromide in isopropanol containing cesium chloride
Alternate Protocol 7	Ethidium bromide in alcohols
Support Protocol 4	Analysis for ethidium bromide and propidium iodide
Basic Protocol 6	Hydrazine
Alternate Protocol 8	Spills of hydrazine
Basic Protocol 7	Hydrogen peroxide
Basic Protocol 8	Iodine
Basic Protocol 9	Mercury compounds
Alternate Protocol 9	Waste water containing mercury

Basic Protocol 10	PMSF in buffer
Alternate Protocol 10	PMSF in isopropanol or dimethyl sulfoxide
Alternate Protocol 11	Bulk quantities of PMSF
Support Protocol 6	Analysis for PMSF
Basic Protocol 11	Sodium azide
Support Protocol 7	Analysis for sodium azide
Support Protocol 8	Analysis for nitrite

Destruction and decontamination are >99%. Support Protocol 1 is used to test for the presence of benzidine and diaminobenzidine.

Materials

Benzidine or diaminobenzidine tetrahydrochloride dihydrate
0.1 M HCl
0.2 M potassium permanganate (prepare immediately before use)
2 M sulfuric acid
Sodium metabisulfite
10 M potassium hydroxide (KOH)

Additional reagents and equipment for testing for the presence of aromatic amines (see Support Protocol 1)

BCU IASI / CENTRAL UNIVERSITY LIBRARY

1. For each 9 mg benzidine, add 10 ml of 0.1 M HCl *or* for each 9 mg of diaminobenzidine tetrahydrochloride dihydrate, add 10 ml water. Stir the solution until the aromatic amine has completely dissolved.
2. For each 10 ml of solution, add 5 ml of 0.2 M potassium permanganate and 5 ml of 2 M sulfuric acid. Allow the mixture to stand for ≥10 hr.
3. Add sodium metabisulfite until the solution is decolorized.
4. Add 10 M KOH to make the solution strongly basic, pH >12.

   CAUTION: *This reaction is exothermic.*
5. Dilute with 5 vol water and filter through filter paper to remove manganese compounds.
6. Test the filtrate for the presence of benzidine or diaminobenzidine (see Support Protocol 1).
7. Neutralize the filtrate with acid and discard.

Decontamination of Spills Involving Benzidine and Diaminobenzidine

ALTERNATE PROTOCOL 1

Additional Materials (also see Basic Protocol 1)

Glacial acetic acid
1:1 (v/v) 0.2 M potassium permanganate/2 M sulfuric acid (prepare immediately before use)

Absorbent material (e.g., paper towels or Kimwipes)
High-efficiency particulate air (HEPA) vacuum (Fisher)

Additional reagents and equipment for testing for the presence of aromatic amines (see Support Protocol 1)

CAUTION: This procedure may damage painted surfaces and Formica.

1. Remove as much of the spill as possible using absorbents and high-efficiency particulate air (HEPA) vacuuming.
2. Wet the surface with glacial acetic acid until all the amines are dissolved, then add an excess of 1:1 (v/v) 0.2 M potassium permanganate/2 M sulfuric acid to the spill area. Allow the mixture to stand ≥10 hr.
3. Ventilate the area and decolorize with sodium metabisulfite.
4. Mop up the liquid with paper towels. Squeeze the solution out of the towels. Discard towels as hazardous solid waste.
5. Add 10 M KOH to basify the solution.

   CAUTION: *This reaction is exothermic.*
6. Dilute with 5 vol water and filter through filter paper to remove manganese compounds.
7. Test the filtrate for the presence of benzidine or diaminobenzidine (see Support Protocol 1).
8. Neutralize the filtrate with acid and discard it.
9. Verify complete decontamination by wiping the surface with a paper towel moistened with water and squeezing the liquid out of the towel. Test the liquid for the presence of benzidine or diaminobenzidine (see Support Protocol 1).

CHIMIE

BCU IAŞI / CENTRAL UNIVERSITY LIBRARY

ALTERNATE PROTOCOL 2

Decontamination of Aqueous Solutions of Benzidine and Diaminobenzidine

The enzyme horseradish peroxidase catalyzes the oxidation of the amine to a radical and the radical diffuses into solution and polymerizes. The polymers are insoluble and fall out of solution.

Additional Materials (also see Basic Protocol 1)

Aqueous solution of benzidine or diaminobenzidine
3% (v/v) hydrogen peroxide
Horseradish peroxidase (see recipe)
1:1 (v/v) 0.2 M potassium permanganate/2 M sulfuric acid
5% (w/v) ascorbic acid
Porous glass filter *or* Sorvall GLC-1 centrifuge or equivalent

Additional reagents and equipment for testing for the presence of aromatic amines (see Support Protocol 1)

1. Adjust the pH of the aqueous benzidine or diaminobenzidine solution to 5 to 7 with acid or base and dilute so the concentration of aromatic amines is ≤100 mg/liter.
2. For each liter of solution, add 3 ml of 3% hydrogen peroxide and 300 U horseradish peroxidase. Let the mixture stand 3 hr.
3. Remove the precipitate by filtering the solution through a porous glass filter or by centrifuging 5 min, room temperature, to pellet the precipitate.

   The precipitate is mutagenic and should be treated as hazardous waste.
4. Immerse the porous glass filter in 1:1 (v/v) 0.2 M potassium permanganate/2 M sulfuric acid.
5. For each liter of filtrate, add 100 ml of 5% ascorbic acid.
6. Test the filtrate for the presence of aromatic amines (see Support Protocol 1).
7. Discard the decontaminated filtrate.

SUPPORT PROTOCOL 1

Analytical Procedures to Detect Benzidine and Diaminobenzidine

Reversed-phase HPLC (*UNIT 11.6*) is used to test for the presence of aromatic amines. The limit of detection is 1 µg/ml for benzidine and 0.25 µg/ml for diaminobenzidine.

Materials

Filtrate from decontaminated aromatic amine (see Basic Protocol 1, Alternate Protocol 1, or Alternate Protocol 2)
10:30:20 (v/v/v) acetonitrile/methanol/1.5 mM potassium phosphate buffer (benzidine) *or* 75:25 (v/v) methanol/1.5 mM potassium phosphate buffer (diaminobenzidine)
1.5 mM potassium phosphate buffer: equimolar amounts of 1.5 mM dibasic potassium phosphate and 1.5 mM monobasic potassium phosphate
250-mm × 4.6-mm-i.d. Microsorb C-8 reversed-phase HPLC column (Rainin Instrument) or equivalent

Additional reagents and equipment for reversed-phase liquid chromatography (*UNIT 11.6*)

Analyze the solution by reversed-phase HPLC using a 250-mm × 4.6-mm-i.d. Microsorb C-8 column. To detect benzidine, elute with 10:30:20 (v/v/v) acetonitrile/methanol/1.5 mM potassium phosphate buffer at a flow rate of 1.5 ml/min and with UV detection at 285 nm. To detect diaminobenzidine, elute with 75:25 (v/v) methanol/1.5 mM potassium phosphate buffer at a flow rate of 1 ml/min and with UV detection at 300 nm.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Disposal of Chlorotrimethylsilane and Dichlorodimethylsilane

BASIC PROTOCOL 2

Silane-containing compounds are hydrolyzed to hydrochloric acid and polymeric silicon-containing material (Patnode and Wilcock, 1946).

1. Hydrolyze silane-containing compounds by cautiously adding 5 ml silane to 100 ml vigorously stirred water in a flask. Allow the resulting suspension to settle.
2. Remove any insoluble material by filtration and discard it with the solid or liquid hazardous waste.
3. Neutralize the aqueous layer with base and discard it.

Disposal of Cyanides and Cyanogen Bromide

BASIC PROTOCOL 3

Inorganic cyanides (e.g., NaCN) and cyanogen bromide (CNBr) are oxidized by sodium hypochlorite (NaOCl; e.g., Clorox) in basic solution to the much less toxic cyanate ion (Lunn and Sansone, 1985). Destruction is >99.7%.

Materials

Cyanide (e.g., NaCN) or cyanogen bromide (CNBr)
1 M NaOH
5.25% (v/v) sodium hypochlorite (NaOCl; e.g., Clorox bleach)

Additional reagents and equipment for testing for the presence of cyanide (see Support Protocol 2)

1. Dissolve cyanide in water to give a concentration ≤25 mg/ml *or* dissolve CNBr in water to give a concentration ≤60 mg/ml.

   If necessary dilute aqueous solutions so the concentration of NaCN or CNBr does not exceed the limit.

2. Mix 1 vol NaCN or CNBr solution with 1 vol of 1 M NaOH and 2 vol fresh 5.25% NaOCl. Stir the mixture 3 hr.

   IMPORTANT NOTE: *With age Clorox bleach may become ineffective; use of fresh bleach is strongly recommended.*

3. Test the reaction mixture for the presence of cyanide (see Support Protocol 2).
4. Neutralize the reaction mixture and discard it.

Analytical Procedure to Detect Cyanide

SUPPORT PROTOCOL 2

This protocol is used to detect cyanide or cyanogen bromide at ≥3 µg/ml.

Materials

Cyanide or cyanogen bromide decontamination reaction mixture (see Basic Protocol 3)
Phosphate buffer (see recipe)
Cyanide detection reagent (see recipe)
10 mg/ml sodium ascorbate (prepare fresh daily)
100 mg/liter NaCN (prepare fresh weekly)
10 mg/ml chloramine-T (prepare fresh daily)
Sorvall GLC-1 centrifuge or equivalent

1. If necessary to remove suspended solids, centrifuge two 1-ml aliquots of the reaction mixture 5 min at room temperature. Add each supernatant to 4 ml phosphate buffer.
2. If an orange or yellow color appears, add 10 mg/ml sodium ascorbate dropwise until the mixture is colorless, but do not add more than 2 ml.

BOSTON / CENTRAL UNIVERSITY LIBRARY

3. Add 200 µl of 100 mg/liter NaCN to one reaction mixture.
4. Add 1 ml of 10 mg/ml chloramine-T to each tube. Shake the tubes and let them stand 1 to 2 min.
5. Add 1 ml cyanide detection reagent, shake, and let stand 5 min.

   A blue color indicates the presence of cyanide. If destruction has been complete and the analytical procedure has been carried out correctly, the untreated reaction mixture should be colorless and the control solution, which contains NaCN, should be blue.
6. If necessary to remove suspended solids, centrifuge tubes 5 min at room temperature. Measure the absorbance at 605 nm with appropriate standards and blanks.

BASIC PROTOCOL 4

Disposal of Diisopropyl Fluorophosphate in Buffer or Water

Diisopropyl fluorophosphate can be degraded by adding 1 M NaOH to solutions of DFP in buffer, water (see Basic Protocol 4), or *N,N*-dimethylformamide (DMF; see Alternate Protocol 3) and to bulk quantities of DFP (see Alternate Protocol 4; Lunn and Sansone, 1994a,d). Decontaminating spills is also described (see Support Protocol 3). The product is diisopropylphosphate. The pH should be ≥12, and destruction is >99.8%.

Materials

Solutions of diisopropyl fluorophosphate in buffer or water
1 M NaOH

1. To each 1 ml of 10 mM DFP in buffer or water add 200 ml of 1 M NaOH and check that the reaction mixture is strongly basic (pH ≥12).
2. Allow the reaction mixture to stand 18 hr at room temperature, analyze for completeness of destruction, neutralize, and discard it.

   An analytical procedure for DFP, based on its inhibitory effect on the activity of chymotrypsin, is quite involved, and the reader should refer to Lunn and Sansone (1994a,d) for full details.

   The choice of neutralizing agent is not critical. Acetic acid works well, but any acid may be used.

ALTERNATE PROTOCOL 3

Disposal of Diisopropyl Fluorophosphate in *N,N*-Dimethylformamide

Additional Materials (also see Basic Protocol 4)

Solutions of diisopropyl fluorophosphate in *N,N*-dimethylformamide

1. To each 1 ml of 200 mM DFP in DMF add 2 ml of 1 M NaOH and check that the reaction mixture is strongly basic (pH ≥12).
2. Allow the reaction mixture to stand 18 hr at room temperature, analyze for completeness of destruction, neutralize, and discard it.

   See Lunn and Sansone (1994a,d) for full details on analyzing for DFP activity.

ALTERNATE PROTOCOL 4

Disposal of Bulk Quantities of Diisopropyl Fluorophosphate

Additional Materials (also see Basic Protocol 4)

Bulk quantities of diisopropyl fluorophosphate

1. To each 40 ml of pure DFP add 1 ml of 1 M NaOH and check that the reaction mixture is strongly basic (pH ≥12).

BCU IASI / CENTRAL UNIVERSITY LIBRARY

2. Stir the reaction mixture 1 hr at room temperature, analyze for completeness of destruction, neutralize, and discard it.

See Lunn and Sansone (1994a,d) for full details on analyzing for DFP activity.

Decontamination of Spills Involving Diisopropyl Fluorophosphate

SUPPORT PROTOCOL 3

Additional Materials (also see Basic Protocol 4)

Spills or equipment contaminated with diisopropyl fluorophosphate

1. Add at least 1 ml of 1 M NaOH for each 40 ml of DFP that is estimated to be present. Add more NaOH if required to thoroughly wet all contaminated surfaces. Check that the reaction mixture is strongly basic (pH ≥12) and make sure that all the oily DFP has dissolved.
2. Allow to stand at least 2 hr and preferably 18 hr at room temperature, analyze the solution for completeness of destruction, neutralize, and discard it.

Decontamination is more efficient if it is possible to agitate or stir the reaction mixture (e.g., when the inside of a flask is being decontaminated).

3. Clean the equipment or the spill area in a conventional fashion with soap and water.

Disposal of Ethidium Bromide and Propidium Iodide

BASIC PROTOCOL 5

Ethidium bromide and propidium iodide in water and buffer solutions may be degraded by reaction with sodium nitrite and hypophosphorous acid in aqueous solution (Lunn and Sansone, 1987). Destruction is >99.87%. This reaction may also be used to decontaminate equipment contaminated with ethidium bromide (see Alternate Protocol 5; Lunn and Sansone, 1989) and to degrade ethidium bromide in organic solvents (see Alternate Protocol 6 and Alternate Protocol 7; Lunn and Sansone, 1990). Ethidium bromide is frequently extracted from nucleic acids using organic solvents. Ethidium bromide and propidium iodide may also be removed from aqueous solution by adsorption onto Amberlite XAD-16 resin.

Materials

Ethidium bromide– or propidium iodide–containing solution in water, buffer, or 1 g/ml cesium chloride
5% (v/v) hypophosphorous acid (prepare fresh daily by diluting commercial 50% reagent 1/10)
0.5 M sodium nitrite (prepare fresh daily)
Sodium bicarbonate
Additional reagents and equipment for testing for the presence of ethidium bromide or propidium iodide (see Support Protocol 4)

1. If necessary, dilute the ethidium bromide– or propidium iodide–containing solution so the concentration of ethidium bromide or propidium iodide is ≤0.5 mg/ml.
2. For each 100 ml solution, add 20 ml of 5% hypophosphorous acid solution and 12 ml of 0.5 M sodium nitrite. Stir briefly and let stand 20 hr.
3. Neutralize the reaction mixture by adding sodium bicarbonate until the evolution of gas ceases.
4. Test the reaction mixture for the presence of ethidium bromide or propidium iodide (see Support Protocol 4).
5. Discard the decontaminated reaction mixture.

BOSTON CENTRAL UNIVERSITY LIBRARY

ALTERNATE PROTOCOL 5

Decontamination of Equipment Contaminated with Ethidium Bromide

Glass, stainless steel, Formica, floor tile, and the filters of transilluminators have been successfully decontaminated using this protocol. No change in the optical properties of the transilluminator filter could be detected, even after a number of decontamination cycles.

Materials

Equipment contaminated with ethidium bromide
Decontamination solution: 0.2 M sodium nitrite/3.3% (v/v) hypophosphorous acid (prepare just before use)
Sodium bicarbonate

Additional reagents and equipment for testing for the presence of ethidium bromide (see Support Protocol 4)

1. Wash the equipment once with a paper towel soaked in decontamination solution.

   The pH of the decontamination solution is 1.8. If this would be too corrosive for the surface to be decontaminated, wash the surface with a paper towel soaked in water.

2. Wash the surface five times with paper towels soaked in water, using a fresh towel each time.
3. Soak all the towels 1 hr in decontamination solution.
4. Neutralize the decontamination solution by adding sodium bicarbonate until the evolution of gas ceases.
5. Test the decontamination solution for the presence of ethidium bromide (see Support Protocol 4).
6. Discard the decontamination solution and the paper towels as nonhazardous liquid and solid wastes.

ALTERNATE PROTOCOL 6

Decontamination of Ethidium Bromide in Isopropanol Saturated with Cesium Chloride

Materials

Ethidium bromide in isopropanol saturated with cesium chloride
Decontamination solution: 0.2 M sodium nitrite/3.3% (v/v) hypophosphorous acid (prepare just before use)
Sodium bicarbonate

Additional reagents and equipment for testing for the presence of ethidium bromide (see Support Protocol 4)

1. If necessary, dilute the ethidium bromide/isopropanol/cesium chloride so the concentration of ethidium bromide is ≤1 mg/ml.
2. For each volume of ethidium bromide solution, add 4 vol decontamination solution. Stir the reaction mixture 20 hr.
3. Neutralize the reaction mixture by adding sodium bicarbonate until the evolution of gas ceases.
4. Test the reaction mixture for the presence of ethidium bromide (see Support Protocol 4).
5. Discard the decontaminated solution.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Decontamination of Ethidium Bromide in Isoamyl Alcohol and 1-Butanol

ALTERNATE PROTOCOL 7

Materials

Ethidium bromide in isoamyl alcohol or 1-butanol
Decontamination solution: 0.2 M sodium nitrite/3.3% (v/v) hypophosphorous acid (prepare just before use)
Activated charcoal
Sodium bicarbonate
Separatory funnel

Additional reagents and equipment for testing for the presence of ethidium bromide (see Support Protocol 4)

1. If necessary, dilute the ethidium bromide/isoamyl alcohol or ethidium bromide/1-butanol so the concentration of ethidium bromide is ≤1 mg/ml.
2. For each volume of ethidium bromide solution, add 4 vol decontamination solution. Stir the two-phase reaction mixture rapidly for 72 hr.
3. For each 100 ml of reaction mixture, add 2 g activated charcoal. Stir another 30 min.
4. Filter the reaction mixture.
5. Neutralize the filtrate by adding sodium bicarbonate until the evolution of gas ceases. Separate the layers using a separatory funnel.

   More alcohol may tend to separate from the aqueous layer on standing.
6. Test the alcohol and aqueous layers for the presence of ethidium bromide (see Support Protocol 4).
7. Discard the alcohol and aqueous layers appropriately. Discard the activated charcoal as solid waste.

   The aqueous layer contains 4.6% 1-butanol or 2.3% isoamyl alcohol.

Analytical Procedure to Detect Ethidium Bromide or Propidium Iodide

SUPPORT PROTOCOL 4

This protocol is used to verify that solutions no longer contain ethidium bromide or propidium iodide. The limits of detection are 0.05 parts per million (ppm) for ethidium bromide and 0.1 ppm for propidium iodide.

Materials

Reaction mixture containing ethidium bromide or propidium iodide (see Basic Protocol 5 or Alternate Protocol 5, 6, or 7)
TBE electrophoresis buffer, pH 8.1 (see recipe)
20 µg/ml calf thymus DNA in TBE electrophoresis buffer, pH 8.1
Spectophotofluorometer *or* hand-held UV lamp

1. Mix 100 µl reaction mixture containing ethidium bromide or propidium iodide with 900 µl TBE electrophoresis buffer.
2. Add 1 ml of 20 µg/ml calf thymus DNA. Prepare a blank solution (100 µl water + 900 µl TBE electrophoresis buffer + 1 ml of 20 µg/ml calf thymus DNA) and control solutions containing known quantities of ethidium bromide or propidium iodide. Let the mixtures stand 15 min.
3. To detect ethidium bromide, measure the fluorescence with an excitation wavelength of 540 nm and an emission wavelength of 590 nm. To detect propidium iodide,

BOURNS / CENTRAL UNIVERSITY LIBRARY

measure the fluorescence with an excitation wavelength of 350 nm and an emission wavelength of 600 nm.

If a spectrophotofluorometer is not available, fluorescence of ethidium bromide can be qualitatively determined using a hand-held UV lamp on the long-wavelength setting (Lunn and Sansone, 1991c).

BASIC PROTOCOL 6

Disposal of Hydrazine

Hydrazine may be oxidized with potassium permanganate in sulfuric acid (Castegnaro et al., 1986). Destruction is >99.997%. This method can also be adapted for the decontamination of spills of hydrazine (see Alternate Protocol 8). The limit of detection for hydrazine is 10 µg/liter.

CAUTION: This procedure works only for hydrazine itself. Oxidation of methylated hydrazines may result in the generation of carcinogenic nitrosamines and should not be attempted. However, hydrazine and methylated hydrazines can be reduced with nickel-aluminum alloy without producing nitrosamines (Lunn et al., 1983).

Materials

Hydrazine
18.3 M (concentrated) sulfuric acid
Potassium permanganate
Sodium metabisulfite
10 M potassium hydroxide (KOH)
1 M HCl
Hydrazine detection reagent (see recipe)

Perform decontamination

1. Dissolve 25 mg hydrazine in 10 ml water.
2. Add 1 ml concentrated sulfuric acid.

   CAUTION: *This reaction is exothermic.*
3. Add 290 mg potassium permanganate. Stir 16 hr.
4. At the end of the reaction, decolorize the solution with sodium metabisulfite.
5. Make the solution strongly basic by adding 10 M KOH to pH >12.

   CAUTION: *This reaction is exothermic.*
6. Dilute the reaction mixture with 5 vol water.
7. Filter through filter paper to remove manganese compounds.

Analyze the filtrate for hydrazine

8. Neutralize the filtrate with acid.
9. Add 2-ml filtrate to 2 ml of 1 M HCl and 2 ml hydrazine detection reagent. Measure the absorbance at 458 nm against a suitable blank to test for the presence of hydrazine.
10. Discard the decontaminated filtrate.

RCU IASI / CENTRAL UNIVERSITY LIBRARY

Decontamination of Spills of Hydrazine

ALTERNATE PROTOCOL 8

This protocol is used to decontaminate spills of hydrazine. It may damage painted surfaces or Formica.

Additional Materials (also see Basic Protocol 6)

3 M sulfuric acid
Potassium permanganate solution: 0.3 M potassium permanganate (47.4 g/liter) in 3 M sulfuric acid (prepare fresh)
Absorbent (e.g., paper towels or Kimwipes)

Decontaminate the spill

1. Add 3 M sulfuric acid to the spill and remove as much of the spill as possible with an absorbent.
2. Place the absorbent material in an appropriate solvent and decontaminate it (see Basic Protocol 6).
3. Cover the spill area with potassium permanganate solution. Let the mixture stand overnight.
4. Decolorize the mixture with sodium metabisulfite. Remove the solution with absorbent.

Analyze absorbed liquid

5. Squeeze out the absorbent. Discard absorbent as hazardous solid waste.
6. Make the solution strongly basic with 10 M KOH.

   CAUTION: *This reaction is exothermic.*
7. Dilute the solution with 5 vol water.
8. Filter the solution through filter paper to remove manganese compounds.
9. Neutralize the filtrate.
10. Add 2-ml filtrate to 2 ml of 1 M HCl and 2 ml hydrazine detection reagent. Measure absorbance at 458 nm against a suitable blank to test for the presence of hydrazine.
11. Discard the decontaminated filtrate.
12. Verify decontamination by taking wipe samples of the area using pieces of absorbent moistened with water to wipe over the area. Squeeze the water out of the absorbent and test for hydrazine as described in step 10.
13. Clean the surface in a conventional manner with soap and water.

Disposal of Hydrogen Peroxide

BASIC PROTOCOL 7

Hydrogen peroxide can be reduced with sodium metabisulfite (Lunn and Sansone, 1994a).

Materials

30% hydrogen peroxide
10% (w/v) sodium metabisulfite
10% (w/v) potassium iodide
1 M HCl
1% (w/v) starch indicator solution

BOSTON / CENTRAL UNIVERSITY LIBRARY

1. Add 5 ml of 30% hydrogen peroxide to 100 ml of 10% sodium metabisulfite. Stir the mixture at room temperature until the temperature starts to drop, indicating that the reaction is over.

2. Test for the presence of hydrogen peroxide by adding a few drops of the reaction mixture to an equal volume of 10% potassium iodide. Add a few drops of 1 M HCl to acidify the reaction mixture, then add a drop of 1% starch indicator solution.

   A deep blue color indicates the presence of excess oxidant. If necessary, add more 10% sodium metabisulfite until the starch test is negative.

3. Discard the decontaminated mixture.

BASIC PROTOCOL 8

Reduction of Iodine

Iodine is reduced with sodium metabisulfite to iodide (Lunn and Sansone, 1994b).

Materials

Iodine
10% (w/v) sodium metabisulfite
1 M HCl
1% (w/v) starch indicator solution

1. Add 5 g iodine to 100 ml of 10% sodium metabisulfite. Stir the mixture until the iodine has completely dissolved.

2. Acidify a few drops of the reaction mixture by adding a few drops of 1 M HCl. Add 1 drop of 1% starch indicator solution.

   A deep blue color indicates the presence of iodine. If reduction is not complete, add more sodium metabisulfite solution.

3. Dispose of the decontaminated solution.

BASIC PROTOCOL 9

Disposal of Mercury Compounds

Solutions of mercuric acetate can be decontaminated using Dowex 50X8-100, a strongly acid gel-type ion-exchange resin with a sulfonic acid functionality. Solutions of mercuric chloride can be decontaminated using Amberlite IRA-400(Cl), a strongly basic gel-type ion-exchange resin with a quaternary ammonium functionality. The final concentration of mercury is <3.8 ppm (Lunn and Sansone, 1994a). On a small scale it is most convenient to stir the resin in the solution to be decontaminated, but on a larger scale, or for routine use, it may be more convenient to pass the solution through a column packed with the resin. Although the volume of waste that must be disposed of is greatly reduced using this technique, a small amount of waste (i.e., the resin contaminated with mercury) remains and must be discarded appropriately. Resin can be regenerated by washing with acid, but the concentrated metal-containing solution generated by this must also be disposed of appropriately. Mercury may also be removed from laboratory waste water using a column of iron powder (see Alternate Protocol 9). Support Protocol 5 is used to detect the presence of mercury.

Materials

Solution containing mercuric acetate *or* mercuric chloride
Dowex 50X8-100 ion-exchange resin *or* Amberlite IRA-400 (Cl) ion-exchange resin

Additional reagents and equipment to test for the presence of mercury (see Support Protocol 5)

BCU IASI CENTRAL UNIVERSITY LIBRARY

1a. *For mercuric acetate:* For each 200 ml of solution containing ≤1600 ppm mercuric acetate, add 1 g Dowex 50X8-100 ion-exchange resin. Stir the mixture 1 hr, then filter through filter paper.

1b. *For mercuric chloride:* For each 200 ml of solution containing ≤1350 ppm mercuric chloride, add 1 g Amberlite IRA-400(Cl) ion-exchange resin. Stir the mixture 6 hr, then filter through filter paper.

The speed and efficiency of decontamination will depend on factors such as the size and shape of the flask and the rate of stirring.

3. Test the filtrate for the presence of mercury (see Support Protocol 5).

4. Discard the decontaminated filtrate and the mercury-containing resin appropriately.

Decontamination of Waste Water Containing Mercury

ALTERNATE PROTOCOL 9

Laboratory waste water that contains mercury is decontaminated by passing it through a column of iron powder. The mercury forms mercury amalgam and stays on the column. Some metallic mercury remains in solution but this can be removed by aeration. The final concentration of mercury is <5 ppb (Shirakashi et al., 1986).

Materials

Waste water containing mercury
Iron powder, 60 mesh
6-mm-i.d. column

1. Pack a 6-mm-i.d. column with 1 g of 60-mesh iron powder.

Use a fresh column for each treatment.

2. Pass ≤2 liters of water containing ≤2.5 ppm of mercury through the column at a flow rate of 250 ml/hr.

Solutions containing a higher concentration of mercury may also be treated, but this will result in a higher final concentration of mercury (e.g., treating a 100-ppm solution in this fashion yielded 33 ppb final).

Some iron ends up in solution and can be removed by adjusting the pH to 8. Precipitated $Fe(OH)_3$ can be removed by filtration.

3. Aerate the resulting effluent to remove traces of metallic mercury and continue aeration 30 min after the last of the effluent has emerged from the column. Vent the metallic mercury removed from the solution by aeration into the fume hood or capture it in a mercury trap.

The effluent contains <5 ppb mercury. The presence of iodide or polypeptone may necessitate several treatments to reduce the mercury to an acceptable level.

Analytical Procedure to Detect Mercury

SUPPORT PROTOCOL 5

Atomic absorption spectroscopy with detection at 253.7 nm, a slit width of 0.7 nm, and a limit of detection of 3.8 ppm can be used to determine the concentration of mercury in solution for experiments involving ion-exchange resins. A Hiranuma mercury meter model HG-1 can be used for experiments involving iron powder.

BCU IRSI/CENTRAL UNIVERSITY LIBRARY

BASIC PROTOCOL 10

Disposal of PMSF in Buffer

Phenylmethylsulfonyl fluoride (PMSF) may be degraded by making the buffer solution strongly alkaline (pH ≥12) with 1 M NaOH solution. Stock solutions of PMSF in isopropanol or DMSO can also be degraded by adding 1 M NaOH (see Alternate Protocol 10; Lunn and Sansone, 1994a,c); bulk quantities of PMSF are dissolved in isopropanol before being neutralized (see Alternate Protocol 11). Degradation is >99.9%. A method of detecting PMSF via RP-HPLC is also discussed (see Support Protocol 6).

Materials

Solutions of PMSF in buffer
1 M NaOH
Acetic acid, glacial

Additional reagents and equipment for analyzing PMSF destruction (see Support Protocol 6)

1. For each 10 ml of buffer containing up to 10 mM PMSF, add 1 ml of 1 M NaOH solution. Ensure that the pH is ≥12.
2. After 1 hr neutralize with 1 ml of acetic acid, test for completeness of destruction (see Support Protocol 6), and discard the reaction mixture.

ALTERNATE PROTOCOL 10

Disposal of PMSF in Isopropanol or Dimethyl Sulfoxide

Additional Materials (also see Basic Protocol 10)

Solutions of PMSF in isopropanol or dimethyl sulfoxide

1. Dilute the solution, if necessary, so that the concentration of PMSF does not exceed 100 mM.
2. For each 1 ml of solution add 5 ml of 1 M NaOH, shake to ensure complete mixing, and allow to stand for 24 hr.
3. Neutralize with 1 ml of acetic acid, test for completeness of destruction (see Support Protocol 6), and discard the reaction mixture.

ALTERNATE PROTOCOL 11

Disposal of Bulk Quantities of PMSF

Additional Materials (also see Basic Protocol 10)

Bulk quantities of PMSF

1. Dissolve the PMSF in isopropanol so that the concentration does not exceed 100 mM.

   Stirring may be necessary.
2. For each 1 ml of solution add 5 ml of 1 M NaOH, shake to ensure complete mixing, and allow to stand for 24 hr.
3. Neutralize with 1 ml of acetic acid, test for completeness of destruction (see Support Protocol 6), and discard the reaction mixture.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Analytical Procedure to Detect PMSF

SUPPORT PROTOCOL 6

Materials

Decontaminated and neutralized reaction mixtures
50:50 (v/v) acetonitrile/water
250-mm × 4.6-mm-i.d. Microsorb C-8 reversed-phase HPLC column (Rainin Instrument) or equivalent

Analyze decontaminated and neutralized reaction mixtures by reversed-phase HPLC (RP-HPLC; *UNIT 11.6*) using a 250-mm × 4.6-mm-i.d. Microsorb C-8 column and eluting with 50:50 (v/v) acetonitrile/water at a flow rate of 1 ml/min with UV detection at 220 nm.

Disposal of Sodium Azide

BASIC PROTOCOL 11

Sodium azide can be oxidized by ceric ammonium nitrate (Manufacturing Chemists Association, 1973) to nitrogen (Mason, 1967) or by nitrous acid (National Research Council, 1983) to nitrous oxide (Mason, 1967). Destruction is >99.996%. Sodium azide in buffer solution may also be degraded by the addition of sodium nitrite (Lunn and Sansone, 1994a). The reaction proceeds much more readily at low pH, but if sufficient sodium nitrite is added, it will proceed to completion even at high pH. At low pH, it may be possible to completely degrade the azide present in the buffer with less than the amount of sodium nitrite indicated. However, the reaction mixture must be carefully checked to ensure that no azide remains (see Support Protocol 7). At high pH it is possible for unreacted azide to remain in the presence of excess nitrite. Residual nitrite can be detected using Support Protocol 8.

CAUTION: Some toxic nitrogen dioxide may be produced as a by-product of these reactions, so they should always be carried out in a chemical fume hood.

Materials

Sodium azide or solution containing sodium azide
Ceric ammonium nitrate
10% (w/v) potassium iodide
1 M HCl
1% (w/v) starch indicator solution
Sodium nitrite
4 M sulfuric acid
Litmus paper

Additional reagents and equipment to test for the presence of sodium azide (see Support Protocol 7) *or* nitrite (see Support Protocol 8)

Decontamination using ceric ammonium nitrate

1a. For each gram of sodium azide, add 9 g ceric ammonium nitrate to 30 ml of water, and stir until it has dissolved.

2a. Dissolve each gram of sodium azide in 5 ml water. Add this solution to the ceric ammonium nitrate solution at the rate of 1 ml each min. Stir 1 hr.

If the reaction is carried out on a larger scale, an ice bath may be required for cooling.

3a. Check that the reaction is still oxidizing by adding a few drops of the reaction mixture to an equal volume of 10% potassium iodide. Acidify the mixture with 1 drop of 1 M HCl. Add 1 drop of 1% starch indicator solution.

The deep blue color of the starch-iodine complex indicates that excess oxidant is present. If excess oxidant is not present, add more ceric ammonium nitrate.

BOJIANG / CENTRAL UNIVERSITY LIBRARY

4a. Test for the presence of sodium azide (see Support Protocol 8).

5a. Discard the decontaminated reaction mixture.

Decontamination using sodium nitrite

1b. For each 5 g sodium azide, dissolve 7.5 g sodium nitrite in 30 ml water.

2b. Dissolve each 5 g sodium azide in 100 ml water. Add the sodium nitrite solution with stirring. Slowly add 4 M sulfuric acid until the reaction mixture is acidic to litmus. Stir 1 hr.

CAUTION: *It is important to add the sodium nitrite, then the sulfuric acid. Adding these reagents in reverse order will generate explosive, volatile, toxic hydrazoic acid.*

If the reaction is carried out on a large scale, an ice bath may be required for cooling.

3b. Check that there is excess nitrous acid in the reaction. Add a few drops of the reaction mixture to an equal volume of 10% potassium iodide. Acidify the mixture with 1 drop of 1 M HCl. Add 1 drop starch indicator solution.

The deep blue color of the starch-iodine complex indicates that excess nitrous acid is present. If excess nitrous acid is not present, add more sodium nitrite.

4b. If excess nitrous acid is present, test for the presence of sodium azide (see Support Protocol 7).

5b. Discard the decontaminated reaction mixture.

Decontamination of sodium azide in buffer

1c. If necessary, dilute the buffer solution with water so the concentration of sodium azide is ≤1 mg/ml.

2c. For each 50 ml buffer solution add 5 g sodium nitrite. Stir the reaction 18 hr.

3c. Test for the presence of sodium azide (see Support Protocol 7).

4c. Discard the decontaminated reaction solution.

SUPPORT PROTOCOL 7

Analytical Procedures to Detect Sodium Azide

Sodium azide is analyzed by reacting azide ion with 3,5-dinitrobenzoyl chloride to form 3,5-dinitrobenzoyl azide, which can be detected by reversed-phase HPLC. The limit of detection of this assay is 0.2 µg/ml sodium azide. This protocol works only in the absence of nitrite; Support Protocol 8 should be used to verify that all of the nitrite has been destroyed by sulfamic acid.

Materials

Reaction mixture from sodium azide treated with ceric ammonium nitrate or sodium nitrite
1 M KOH
Acetonitrile
Sodium azide indicator solution (see recipe)
0.2 M HCl
20% (w/v) sulfamic acid
3,5-dinitrobenzoyl chloride
50:50 (v/v) acetonitrile/water

Sorvall GLC-1 centrifuge or equivalent
25-cm × 4.6-mm-id Microsorb C-8 reversed-phase HPLC column (Rainin Instruments) or equivalent

BCU IASL - CENTRAL UNIVERSITY LIBRARY

Additional reagents and equipment for reversed-phase liquid chromatography (*UNIT 11.6*)

To analyze for azide in the presence of ceric salts

1a. To a 10-ml aliquot of the reaction mixture from the treatment of sodium azide with ceric ammonium nitrate, add 40 ml water. Add 5 ml of this diluted solution to 3 ml of 1 M KOH and mix by shaking.

If <3 ml of 1 M KOH is used, precipitation of ceric salts will not be complete.

2a. Centrifuge the mixture 5 min, room temperature.

3a. Remove 2 ml supernatant and add to 1 ml acetonitrile. Add 1 drop sodium azide indicator solution, add 0.2 M HCl dropwise until the mixture turns yellow, then add 1 drop more.

To analyze for azide in the presence of nitrite

1b. To 5 ml of the reaction mixture from sodium azide treated with sodium nitrite add ≥1 ml sulfamic acid to remove excess nitrite. Let stand ≥3 min.

More sulfamic acid solution may be required for strongly basic reaction mixtures or those containing high concentrations of nitrite. Complete removal of nitrite can be checked by using a modified Griess reagent (see Support Protocol 8).

At high pH the reaction between azide and nitrite is quite slow, so the presence of excess nitrite does not mean that all the azide has been degraded.

2b. Add 1 drop sodium azide indicator solution, then basify the mixture by adding 1 M KOH until it turns purple (typically, 3 to 10 ml are required).

3b. Add 2 ml acetonitrile. Add 0.2 M HCl dropwise until the mixture turns yellow, then add 1 drop more.

If >1 ml sulfamic acid is used, add 4 ml acetonitrile.

4. Prepare a 10% (w/v) solution of 3,5-dinitrobenzoyl chloride in acetonitrile.

5. Add 50 µl of 10% dinitrobenzoyl chloride/acetonitrile to the reaction mix (step 3a or 3b). Shake the mixture and let it stand ≥3 min.

Longer standing times have no effect on the HPLC analysis. However, it is crucial to use freshly prepared 3,5-dinitrobenzoyl chloride solution within minutes of its preparation. It is generally most convenient to prepare all the analytical samples with the fresh solution at the beginning of the day and analyze them over the course of the day.

6. Analyze 20 µl of each reaction mixture by reversed-phase HPLC using a mobile phase of 50:50 (v/v) acetonitrile/water with a flow rate of 1 ml/min and UV detection at 254 nm.

The peak for 3,5-dinitrobenzoyl azide elutes at ~9 min.

Analytical Procedure to Detect Nitrite

SUPPORT PROTOCOL 8

This protocol uses a modified Griess reagent to test for the presence of nitrite. The limit of detection of this assay is 0.06 µg/ml nitrite. A similar procedure uses *N*-(1-naphthyl)-ethylenediamine (Helrich, 1990).

Materials

Reaction mixture treated to remove excess nitrite (see Support Protocol 7, step 1b)
α-Naphthylamine
15% (v/v) aqueous acetic acid
Sulfanilic acid solution (see recipe)

BCU IASI / CENTRAL UNIVERSITY LIBRARY

1. Prepare the modified Griess reagent: boil 0.1 g α-naphthylamine in 20 ml water until it dissolves. While the solution is still hot, pour it into 150 ml of 15% aqueous acetic acid. Add 150 ml sulfanilic acid solution.

   This reagent should be stored at room temperature in a brown bottle.

   CAUTION: *α-Naphthylamine is a carcinogen.*

2. Add 3 ml of the reaction mixture treated to remove excess nitrite to 1 ml modified Griess reagent. Let stand 6 min at room temperature.

3. Measure the absorbance at 520 nm against a suitable blank.

REAGENTS AND SOLUTIONS

Use deionized, distilled water in all recipes and protocol steps. For common stock solutions, see ***APPENDIX 2E****; for suppliers, see* ***SUPPLIERS APPENDIX****.*

Cyanide detection reagent

Stir 3.0 g barbituric acid in 10 ml water. Add 15 ml of 4-methylpyridine and 3 ml concentrated HCl while continuing to stir. Cool and dilute to 50 ml with water. Store at room temperature.

CAUTION: *This reaction is exothermic.*

Horseradish peroxidase

Dissolve hydrogen-peroxide oxidoreductase (EC 1.11.1.7 [Type II]; specific activity 150 to 200 purpurogallin U/mg, Sigma) in 1 g/liter sodium acetate to give 30 U/ml. Prepare fresh daily.

For small-scale reactions, a more dilute solution can be used to avoid working with inconveniently small volumes.

Hydrazine detection reagent

1.6 g *p*-dimethylaminobenzaldehyde (0.12 M final)
80 ml ethanol (91% final)
8 ml concentrated HCl (1.05 M final)
Store at room temperature

Phosphate buffer

13.6 g monobasic potassium phosphate (KH_2PO_4; 0.1 M final)
0.28 g dibasic sodium phosphate (Na_2HPO_4; 2 mM final)
3.0 g potassium bromide (KBr; 25 mM final)
1 liter H_2O
Store at room temperature

Potassium bromide is necessary to make the assay for cyanide work correctly.

Sodium azide indicator solution

0.1 g bromocresol purple (0.4% final)
18.5 ml 0.01 M potassium hydroxide (KOH; 7.4 mM final)
H_2O to 25 ml
Store at room temperature

Sulfanilic acid solution

Dissolve 0.5 g sulfanilic acid in 150 ml of 15% (v/v) aqueous acetic acid. Use immediately.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

TBE electrophoresis buffer, pH 8.1

10× stock solution, 1 liter:

108g Tris base (890 mM final)
55 g boric acid (890 nM final)
40 ml 0.5 M EDTA, pH 8.0 (20 mM)
Adjust pH to 8.1

Safe Use of Radioisotopes

The use of radioisotopes to label specific molecules in a defined way has greatly furthered the discovery and dissection of biochemical pathways. The development of methods to inexpensively synthesize such tagged biological compounds on an industrial scale has enabled them to be used routinely in laboratory protocols, including many detailed in this manual. Although most of these protocols involve the use of only microcurie (μCi) amounts of radioactivity, some (particularly those describing the metabolic labeling of proteins within cells; see *UNIT 3.4*) require amounts on the order of tens of millicuries (mCi). In all cases where radioisotopes are used, depending on the quantity and nature of the isotope, certain precautions must be taken to ensure the safety of the scientist. This appendix outlines a few such considerations relevant to the isotopes most frequently used in biological research.

In designing safe protocols for the use of radioactivity, the importance of common sense, based on an understanding of the general principles of isotopic decay and the importance of continuous monitoring with a hand-held radioactivity monitor (e.g., Geiger counter), cannot be overemphasized. In addition, it is also critical to take into account the rules, regulations, and limitations imposed by each specific institution. These are usually not optional considerations: an institution's license to use radioactivity normally depends on strict adherence to such rules.

Many of the protocols described have evolved (and are evolving still) over the years and through the millicuries in the Department of Molecular Biology and Virology at the Salk Institute. The authors are indebted to those who have trained them in the safe use of radioactivity, in particular to the members of the Salk Institute Radiation Safety Department. Most of the designs for the shields and other safety equipment shown in Figures A.2B.1, A.2.B2, and A.2B.3 were created at the Salk Institute in collaboration with Dave Clarkin and Mario Tengco. Safety equipment of similar design is available from several commercial vendors, including CBS Scientific and Research Products International (see *SUPPLIERS APPENDIX*).

BACKGROUND INFORMATION

The Decay Process

As anyone who has taken a basic chemistry course will remember, each element is characterized by its atomic number, defined as the number of orbital electrons or the number of protons in the nucleus of that atom. Isotopes of a given element exist because some atoms of each element, while by definition having the same number of protons, have a different number of neutrons and therefore a different nuclear weight. It should be noted that the number of electrons outside the nucleus remains the same for all isotopes of a given element, and so all isotopes of a given element are equivalent with respect to their chemical reactivity.

Radioactive decay occurs when subatomic particles are released from the nucleus of an atom of a heavy isotope. This often results in the conversion of an atom of one isotope to an isotope of a different element, because the original isotope's atomic number changes after decay. The subatomic particles released from naturally occurring radioisotopes are of three basic types: α and β particles and γ rays.

An α particle is essentially the nucleus of a helium atom, or two protons plus two neutrons. It is a relatively large, heavy particle that moves slowly and usually only across short distances before it encounters some other atom with which it interacts. These particles are released from isotopes with large nuclei (atomic number >82; e.g., plutonium or uranium); such isotopes are not commonly used in biological research.

In contrast to α particles, β particles are light, high-speed charged particles. Negatively charged β particles are essentially electrons of nuclear origin that are released when a neutron is converted to a proton. Release of a β particle thus changes the atomic number and elemental status of the isotope.

γ radiation has both particle and wave properties; its wavelength falls within the range of X-ray wavelengths. The distinction between γ rays and X rays was made when primitive X-ray machines produced X rays with a wavelength longer than those of the γ rays produced naturally by radioisotopes. Modern X-ray machines produce a much broader spectrum of wavelengths, including γ radiation; currently this sort of X-ray radiation is termed γ when it is of nuclear origin. Unlike β-particle release, the release of γ radiation by itself produces an isotopic change rather than an elemental one; however, the resultant nuclei are unstable and often decay further, releasing β particles.

The energy of all α particles and γ rays (measured in electron volts) is fixed, because

Table A.2B.1 Physical Characteristics of Commonly Used Radionuclides[a]

Nuclide	Half-life	Emission	Energy, max (MeV)	Range of emission, max	Approx. specific activity at 100% enrichment (Ci/mg)	Atom resulting from decay	Target organ
^{3}H	12.43 years	β	0.0186	0.42 cm (air)	9.6	$^{3}_{2}He$	Whole body
^{14}C	5370 years	β	0.156	21.8 cm (air)	4.4 mCi/mg	$^{14}_{7}N$	Bone, fat
$^{32}P^{b}$	14.3 days	β	1.71	610 cm (air) 0.8 cm (water) 0.76 cm (Plexiglas)	285	$^{33}_{16}S$	Bone
$^{33}P^{b}$	25.4 days	β	0.249	49 cm	156	$^{33}_{16}S$	Bone
^{35}S	87.4 days	β	0.167	24.4 cm (air)	43	$^{35}_{17}Cl$	Testes
$^{125}I^{c}$	60 days	γ	0.27–0.035	0.2 mm (lead)	14.2	$^{125}_{52}Te$	Thyroid
$^{131}I^{c}$	8.04 days	β	0.606	165 cm (air)	123	$^{130}_{54}Xe$	Thyroid
		γ	0.364	2.4 cm (lead)			

[a]Table compiled based on information in Lederer et al. (1967) and Shleien (1987).
[b]Recommended shielding is Plexiglas; half-value layer measurement is 1 cm.
[c]Recommended shielding is lead; half-value layer measurement is 0.02 mm.

they are of specific composition or wavelength. The energy of β particles, however, varies depending on the atom they originate from (and with concomitant release of neutrinos or antineutrinos that serve to balance the conservation of energy aspect of the decay equation). Thus there are (relatively) high-energy β particles released during the decay of ^{32}P and low-energy β particles released when tritium (^{3}H) decays.

Isotopic decay usually involves a chain or sequence of events rather than a single loss of a particle, because the resultant, equally unstable atoms try to achieve equilibrium. During this course of decay, secondary forms of radiation can be generated that may also pose a hazard to workers. For example, when high-energy β particles released during the decay of ^{32}P encounter the nuclei of atoms with a large atomic number, a strong interaction occurs. The β particle loses some energy in the form of a photon. Such photons are called Bremsstrahlung radiation; they are detectable using a monitor suitable for the detection of γ or X rays.

Following their release, α, β, and γ emissions (as well as secondary forms of radiation) travel varying average distances at varying average speeds, depending on their energy and the density of the material through which they are moving. The distance they actually travel before encountering either the electrons or nucleus of another atom is termed their degree of penetrance. This value is expressed as an average for each type of particle. The energy of the particles released (and therefore their potential penetrance) thus dictates what type of shielding, if any, is necessary for protection against the radiation generated by the decay of a given isotope. α, β, and γ emissions all have the potential, upon encountering an atom, to knock out its electrons, thereby creating ions. Thus, these three types of emissions are called ionizing radiation. The formation of such ions may result in the perturbation of biological processes: therein lies the danger associated with radioactivity!

Table A.2B.1 provides a summary of the factors discussed above for several isotopes commonly used in biochemical research.

Measuring Radioactivity and Individual Exposure to It

The radioactivity of a given substance is measured in terms of its ionizing activity. A Curie by definition is the amount of radioactive material that will produce 3.4×10^{10} disintegration (ions) per second. This, not coincidentally, happens to be the number of disintegrations that occur during the decay of one gram of radium and its decay products. Exposure to such radiation is measured as the amount of energy absorbed by the recipient, which, of course, is directly related to the potential damage such radiation may cause. One rad is the dose of radiation that will cause 100 ergs of energy to be absorbed per gram of irradiated material. Another unit commonly used to measure radiation doses is the rem; this is related to the rad but takes into account a "quality

BCU IASRI CENTRAL UNIVERSITY LIBRARY

factor" based on the type of ionizing radiation being received. For β particles and γ or X rays this factor is 1; therefore, rems β equal rads β. In contrast, the quality factor associated with α particles is 20, so an exposure of one rad due to α particles would be recorded as 20 rem.

The amount or dose of radiation received by materials (cells, scientists, etc.) near the source depends not only on the specific type and energy (penetrance) of the radiation being produced, but also on the subject's distance from the source, the existence of any intervening layers of attenuating material (shielding), and the length of time spent in the vicinity of the radiation source. To best measure such doses, every person working with or around radioactivity should wear an appropriate type of radiation detection badge (in addition to carrying a portable radiation monitor that can give an immediate, approximate reading.) This is normally a requirement (not an option) for compliance with an institution's license to use radioisotopes. Such badges are usually furnished by the safety department and collected at regular intervals for reading by a contracted company. At most institutions, the old-style film badges have been replaced with the more accurate TLDs (thermoluminescent dosimeters). These take advantage of chemicals such as calcium or lithium fluorides which, following exposure to ionizing radiation, will luminesce at temperatures below their normal thermal luminescence threshold. Different types of badges are sensitive to different types of radiation: always be sure to wear one that is appropriate for detecting exposure to the isotope being used! In most places pregnant women are asked to wear a more sensitive (and more expensive) dosimeter to better monitor their (and the developing fetus') exposure. Most often workers will be asked to wear a radiation detection badge on the labcoat lapel in order to measure whole-body radiation. When working with ^{32}P or ^{125}I it is also advisable to wear a ring badge to measure exposure to the unshielded extremities (fingers). The limit set for "acceptable" exposure to whole-body radiation is several-fold less than the limit set for extremities. Nevertheless, we have found that the exposure recorded on ring badges is often significant with respect to the limit for extremities set by our institution.

What is known about the effects on humans of exposure to low levels of radiation (i.e., levels which would be received when briefly handling mCi or μCi amounts of radioactivity)? Not much, for the obvious reason that direct studies have not been undertaken. Accordingly, guidelines for exposure levels are set using extrapolations—either by extrapolating down from population statistics obtained following accidents or disasters (the Chernobyl meltdown, atomic bombings) or by extrapolating up from numbers obtained from animal experiments. Each form of extrapolation is subject to caveats, and given that predictions based on such extrapolations cannot be perfect, most health and safety personnel aim for radiation exposure levels said to be ALARA or "as low as reasonably achievable." Further discussion of exposure limits and the statistics on which they are based may be found in B. Shleien's health physics text (Shleien, 1987). Limiting exposure to radiation can be accomplished by adjusting several parameters of the exposure: the duration of exposure, distance from the source, and the density of the material (air, water, shielding) between the individual and the source.

Time is of the essence

When designing any experiment using radioactivity, every effort should be made to limit the time spent directly handling the vials or tubes containing the radioactive material. Speed should be encouraged in all manipulations, though not to the point of recklessness! Have everything needed for the experiment ready at hand before the radioactivity is introduced into the work area.

Distance helps to determine dose

When possible, experiments involving radioactivity should be performed in an area separate from the rest of the lab. Many institutions require that such work be performed in a designated "hot lab"; however, if many people in the laboratory routinely use radioisotopes, it is less than feasible to move them all into what is usually a smaller space. No matter where an individual is working, it is his or her responsibility to monitor the work area and ensure his or her own safety and the safety of those working nearby by using adequate shielding. Obviously, when handling the radioactive samples, it is necessary to work rapidly behind any required shielding. To protect bystanders, remember that the intensity of radiation from a source (moving through air) falls off in proportion to the square of the distance. Thus, if standing 1 foot away from a source for 5 min would result in an exposure of 45 units, standing 3 feet away for the same amount of time would result in an exposure $(1/3)^2$ of 45 units,

BOSTON CENTRAL UNIVERSITY LIBRARY

or 5 units. This factor is also relevant when considering the storage of large amounts of radioactivity, particularly ^{125}I or ^{32}P, as no amount of shielding can completely eliminate radiation.

Shielding is the key to safety

As mentioned above, the energy of the particle(s) released during the decay of an isotope determines what, if any, type of shielding is appropriate. β particles released during the decay of ^{14}C and ^{35}S possess roughly ten times the energy of those released when ^{3}H decays. All three β particles are of relatively low energy, do not travel very far in air, and cannot penetrate solid surfaces. No barriers are necessary for shielding against this type of β radiation. The major health threat from these isotopes occurs through their accidental ingestion, inhalation, or injection.

β particles released during the decay of ^{32}P have 10-fold higher energy than those released from ^{14}C and pose a significant threat to workers. (One reported hazard is the potential for induction of cataracts in the unshielded eye.) The fact that these high-energy beta particles can potentially generate significant amounts of Bremsstrahlung radiation is the reason that low-density materials are used as the primary layer of shielding for ^{32}P β radiation. Water, glass, and plastic are suitable low-density materials (as opposed to lead). Obviously water is unsuitable as a shielding layer for work on the bench, although it does a reasonable job when samples are incubating in a water bath. Shields made from a thickness of glass sufficient to stop these particles would be extremely heavy and cumbersome (as well as dangerous if dropped). Fortunately, plastic or acrylic materials—variously called Plexiglas, Perspex, or Lucite—are available for shielding against ^{32}P β radiation. Shields as well as storage boxes constructed of various thicknesses of Plexiglas are necessary equipment in laboratories where ^{32}P is used. When mCi amounts of ^{32}P are used at one time it is necessary to also block the Bremsstrahlung radiation by adding a layer of high-density material (such as 4 to 6 mm lead) to the outside of the Plexiglas shield (covering the side farthest from the radioactive source).

γ rays released during the decay of ^{125}I have much higher penetrance than the β particles from ^{32}P decay; this radiation must be stopped by very-high-density material, such as lead. Lead foil of varying thicknesses (2 to 6 mm) can be purchased in rolls and can be cut and molded to cover any container, or taped to a Plexiglas shield (used in this instance for support). Obviously this latter arrangement has the disadvantage that it is impossible to see what one is doing through the shield. For routine shielding of manipulations involving ^{125}I, it is useful to purchase a lead-impregnated Plexiglas shield that is transparent, albeit inevitably very heavy (as well as relatively expensive).

Although it seems logical that the use of more radioactivity necessitates the use of thicker layers of shielding, it is also true that no shielding material is capable of completely stopping all radiation. When deciding how thick is "thick enough," consult the half-value layer measurement for each type of shielding material. This number gives the thickness of a given material necessary to stop half the radiation from a source; Table A.2B.2 lists half-value layer measurements for the β particles released from isotopes commonly used in the biology laboratory. In general, 1 to 2 cm of Plexiglas and/or 0.02 mm of lead are sufficient to shield the amounts of radioactivity used in our experiments.

GENERAL PRECAUTIONS

Before going on to a discussion of specific precautions to be taken with individual isotopes, a short list of general precautions to be taken with all isotopes seems pertinent:

1. Know the rules. Be sure that each individual is authorized to use each particular isotope and uses it in an authorized work area.

2. Don the appropriate apparel. Whenever working at the lab bench, it is good safety practice to wear a labcoat for protection. Disposable paper/synthetic coats of various styles are commercially available: at $4 each these may be conveniently thrown out if contaminated with radioactivity during an experiment, rather than held for decay as might be preferable with cloth coats costing about $30 each. As an alternative, disposable sleeves can be purchased and worn over those of the usual cloth coat. Other necessary accessories include radiation safety badges, gloves, and protective eyewear. It's handy to wear two pairs of gloves at once when using radioactivity; when the outer pair becomes contaminated, it is possible to strip it off and continue working without interruption.

3. Protect the work area as well as the workers. Lab benches and the bases of any shields used should be covered with some sort of disposable, preferably absorbent, paper sheet. Underpads or diapers (the kind normally

Table A.2B.2 Shielding Radioactive Emission[a]

β emitters

used in hospitals) are convenient for this purpose.

4. Use appropriate designated equipment. It is very convenient, where use justifies the expense, to have a few adjustable pipettors dedicated for use with each particular isotope. Likewise, it is good practice to use only certain labeled centrifuges and microcentrifuge rotors for radioactive samples so that all the lab's rotors do not become contaminated. Although such equipment should be cleaned after each use, complete decontamination is often not possible. A few pipettors or a single microcentrifuge can easily be stored (and used) behind appropriate shielding. Actually, contamination of the insides and tip ends of pipettors can be greatly reduced by using tips supplied with internal aerosol barriers; these have recently become very popular for setting up PCR reactions and are available to fit a variety of pipettors. To prevent contamination of the outside of the pipettor's barrel, simply wrap the hand-grip in Parafilm, which can be discarded later. Several manufacturers sell disposable paper inserts for their microcentrifuges that protect the wall of the rotor chamber from contamination that might spin off the outside of sample tubes. Trying to fashion homemade liners of this sort is not recommended, as we have had disastrous experiences using laminated adhesive paper that "unstuck" during microcentrifuge spins. These liners would get caught by the rotor, shattering sample tubes and creating an even bigger mess!

5. Know where to dispose of radioactive waste, both liquid and solid. Most institutions require that radioactive waste be segregated by isotope. This is done not only so that appropriate shielding can be placed around waste containers, but so that some waste can be allowed to decay prior to disposal through normal trash channels. With a decreasing number of radioactive waste disposal facilities able or willing to accept radioactive waste for burial (and a concomitant increase in dumping charges from those that still do) this practice of on-site decay can save an institution thousands of dollars a year in disposal charges.

6. Label your label! It is only common courtesy (as well as common sense) to alert coworkers to the existence of anything and everything radioactive that is left where they may come in contact with it! A simple piece of tape affixed to the sample box—with the investigator's name, the amount and type of isotope, and the date written on it—should do the trick. Yellow hazard tape printed with the international symbol for radioactivity is commercially available in a variety of widths.

7. Monitor radioactivity early and often. Portable radiation detection monitors are essential equipment for every laboratory using radioactivity. No matter how much or how little radioactivity is being used, the investigator

BUCHANAN CENTRAL UNIVERSITY LIBRARY

should keep a hand-held monitor nearby—and it should be on! Turn it on before touching any radioactivity to avoid contaminating the monitor's switch. Use a monitor with the appropriate detection capacity (β for ^{35}S and ^{32}P; γ for ^{125}I) before, during, and after all procedures. The more frequently fingers and relevant equipment are monitored, the more quickly a spill or glove contamination will be detected. Such timely detection will keep both the potential mess and the cleanup time to a minimum. Because low-energy β emitters such as ^{3}H cannot be detected using such monitors, wipe tests of the bench and equipment used are necessary to ensure that contamination of the work area did not occur.

SPECIFIC PRECAUTIONS

The following sections describe precautions to be taken with individual isotopes in specific forms. Although the sections dealing with ^{35}S- or ^{32}P-labeling of proteins in intact cells are presented in terms of mammalian cells, most of the instructions are also pertinent (with minimal and obvious modifications) to the labeling of proteins in other cells (e.g., bacterial, insect).

Working with ^{35}S

Using ^{35}S to label cellular proteins and proteins translated in vitro

As discussed above, the β radiation generated during ^{35}S decay is not strong enough to make barrier forms of shielding necessary. The risk associated with ^{35}S comes primarily through its ingestion and subsequent concentration in various target organs, particularly the testes. Although willful ingestion of ^{35}S seems unlikely, accidental or unknowing ingestion may be more common. As reported several years ago (Meisenhelder and Hunter, 1988), ^{35}S-labeled methionine and cysteine, which are routinely used to label proteins in intact cells and by in vitro translation, break down chemically to generate a volatile radioactive component. The breakdown occurs independent of cellular metabolism. Thus the radioactive component is generated to the same extent in stock vials as in cell culture dishes. The process seems to be promoted by freezing and thawing ^{35}S-labeled materials. The exact identity of this component is not known, although it is probably SO_2 or CH_3SH. What is known is that it dissolves readily in water and is absorbed by activated charcoal or copper.

The amount of this volatile radioactive component released, despite stabilizers added by the manufacturers, is about 1/8000 of the total radioactivity present. The amount of this radioactivity that a scientist is likely to inhale while using these compounds is presumably even smaller. Nevertheless, such a component can potentially contaminate a wide area because of its volatility, and also tends to concentrate in target organs. Thus, it is advisable to thaw vials of ^{35}S-labeled amino acids in a controlled area such as a hood equipped with a charcoal filter. This charcoal filter will become quite contaminated and should be changed every few months. If such an area is not available, the stock vial should be thawed using a needle attached to a charcoal-packed syringe to vent and trap the volatile compound.

Anyone who has ever added ^{35}S-labeled amino acids to dishes of cells for even short periods knows that the incubator(s) used for such labelings quickly become highly contaminated with ^{35}S. Such contamination is not limited to the dish itself, nor to the shelf on which the dish was placed. Rather, the radioactive component's solubility in water allows it to circulate throughout the moist atmosphere of the incubator and contaminate all the inside surfaces of the incubator. For this reason, in laboratories where such metabolic labelings are routine, it is highly convenient to designate one incubator to be used solely for working with ^{35}S-labeled samples. Such an incubator can be fitted with a large honeycomb-style filter, the size of an incubator shelf, made of pressed, activated charcoal. These filters are available from local air-quality-control companies. Such a filter will quickly become quite contaminated with radioactivity and should therefore be monitored and changed as necessary (usually about every three months if the incubator is used several times a week). The water used to humidify the incubator will also become quite "hot" (contaminated with radioactivity); keeping the water in a shallow glass pan on the bottom of the incubator makes it easy to change it after every use, thus preventing contamination from accumulating. Even with the charcoal filter and water as absorbents, the shelves, fan, and inner glass door of the incubator will become contaminated, as will the tray on which the cells are carried and incubated. Routine wipe tests and cleaning when necessary will help to minimize potential spread of this contamination.

If such labelings are done infrequently or there is no "spare" incubator, dishes of cells can be placed in a box during incubation. This box should be made of plastic, which is generally

BCU IAS CENTRAL UNIVERSITY LIBRARY

more easily decontaminated than metal. Along with the dishes of cells, a small sachet made of activated charcoal wrapped loosely in tissue (Kimwipes work well) should be placed in the box. If the box is sealed, it will obviously need to be gassed with the correct mixture of CO_2; otherwise small holes can be incorporated into the box design to allow equilibration with the incubator's atmosphere. In either case, the incubator used for the labeling should be carefully monitored for radioactivity after each experiment.

Working with ^{32}P

μCi amounts of ^{32}P

The amount of ^{32}P-labeled nucleotide used to label nucleic acid probes for northern or Southern blotting is typically under 250 μCi, and the amount of [γ-^{32}P]ATP used for in vitro phosphorylation of proteins does not usually exceed 50 μCi for a single kinase reaction (or several hundred μCi per experiment). However, handling even these small amounts, given the time spent on such experiments, can result in an unacceptable level of exposure if proper shielding is not employed. With no intervening shielding, the dose rate 1 cm away from 1 mCi ^{32}P is 200,000 mrads/hr; the local dose rate to basal cells resulting from a skin contamination of 1 μCi/cm^2 is 9200 mrads/hr (Shleien, 1987). Such a skin contamination could be easily attained though careless pipetting and the resultant creation of an aerosol of radioactive microdroplets, because the concentration of a typical stock solution of labeled nucleotide may be 10 μCi/μl.

For proper protection during this sort of experiment, besides the usual personal attire (glasses, coat, safety badges, and gloves) it is necessary to use some form of Plexiglas screen between the body and the samples (see Fig. A.2B.1, panel A). Check the level of radiation coming through the outside of the shield with a portable monitor to be sure the thickness of the Plexiglas is adequate. Hands can be shielded from some exposure by placing the sample tubes in a solid Plexiglas rack, which is also useful for transporting samples from the bench to a centrifuge or water bath (see Fig. A.2B.1, panel B).

Experiments of these types often include an incubation step performed at a specific temperature, usually in a water bath. Although the water surrounding the tubes or hybridization bags will effectively stop β radiation, shielding should be added over the top of the tubes (where there is no water)—e.g., a simple flat piece of Plexiglas. If the frequency of usage justifies the expense, an entire lid for the water bath can be constructed from Plexiglas. When hybridization reactions are performed in bags, care should be taken to monitor (and shield) the apparatus used to heat-seal the bags.

The waste generated during the experiments should also be shielded. It is convenient to have a temporary waste container right on the bench. Discard pipette tips and other solid waste into a beaker lined with a plastic bag and placed behind the shield. This bag can then be emptied into the appropriate shielded laboratory waste container when the experiment is done. Liquid waste can be pipetted into a disposable tube set in a stable rack behind the shield (see Fig. A.2B.1, panel C).

When radiolabeled probes or proteins must be gel-purified, it may be necessary to shield the gel apparatus during electrophoresis if the samples are particularly hot. Be advised that the electrophoresis buffer is likely to become very radioactive if the unincorporated label is allowed to run off the bottom of the gel; check with a radiation safety officer for instructions on how to dispose of such buffer. It is also prudent to check the gel plates with a portable detection monitor after the electrophoresis is completed, because they sometimes become contaminated as well.

mCi amounts of ^{32}P

In order to study protein phosphorylation in intact mammalian cells, cells in tissue culture dishes are incubated in phosphate-free medium with ^{32}P-labeled orthophosphate for a period of several hours or overnight to label the proteins. The amount of ^{32}P used in such labelings can be substantial. Cells are normally incubated in 1 to 2 mCi of ^{32}P/ml labeling medium; for each 6-cm dish of cells, 2.5 to 5 mCi ^{32}P may be used. When this figure is multiplied by the number of dishes necessary per sample, and the number of different samples in each experiment, it is clear that the amount of ^{32}P used in one experiment can easily reach 25 mCi or more. Because so much radioactivity is used in the initial labeling phase of such experiments, it is necessary for a researcher to take extra precautions in order to adequately shield him or herself and coworkers.

When adding label to dishes of cells, it is important to work as rapidly as possible. An important contribution to the speed of these manipulations is to have everything that will be needed at hand before even introducing the

BOWLING GREEN STATE UNIVERSITY LIBRARY

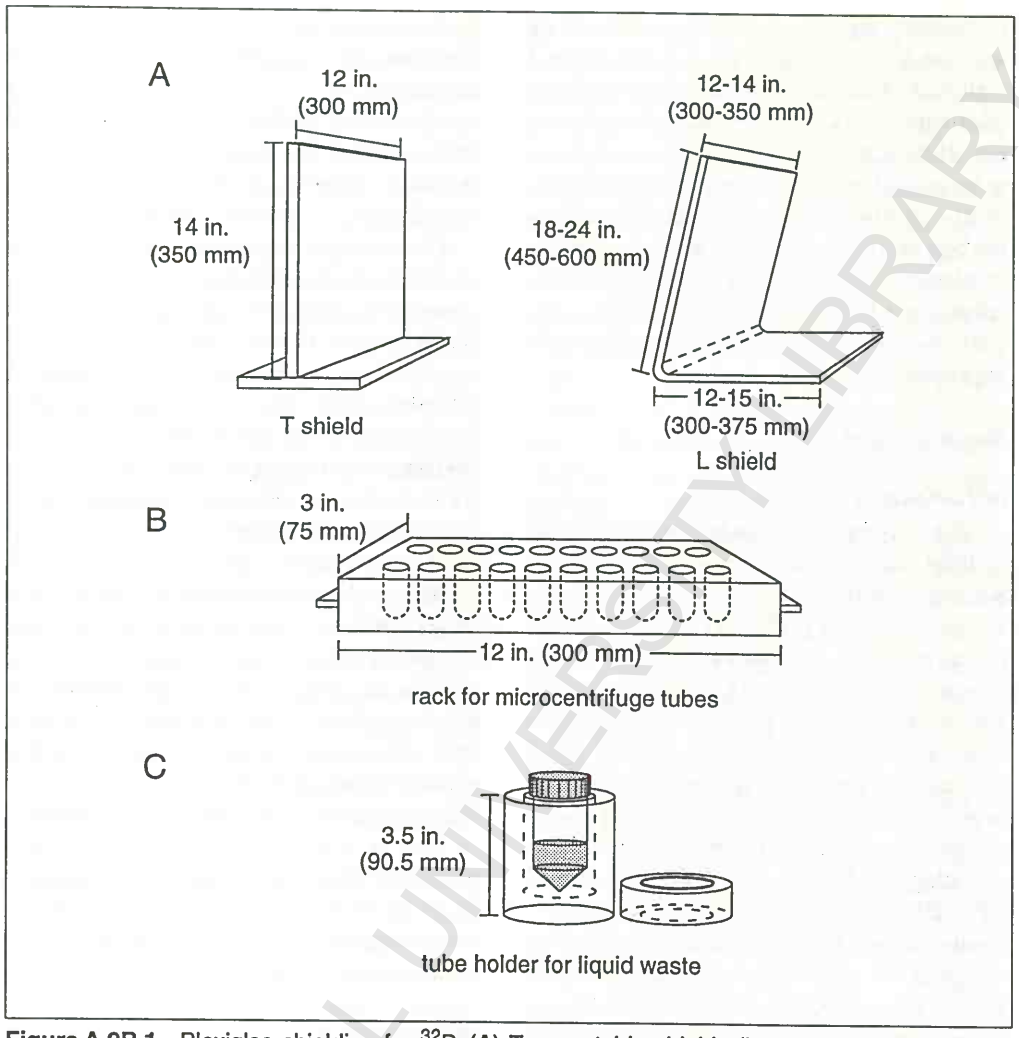

Figure A.2B.1 Plexiglas shielding for ^{32}P. (**A**) Two portable shields (L and T design) made of 0.5-in. Plexiglas. Either can be used to directly shield the scientist from the radioactivity he or she is using. Turned on its side, the L-shaped shield can be used to construct two sides of a cage around a temporary work area, providing shielding for other workers directly across or to the sides of the person working with ^{32}P. (**B**) Tube rack for samples in microcentrifuge tubes. (**C**) Tube holder for liquid waste collection.

label into the work area. Prepare the work area, arranging shielding and covering the bench with diapers, in advance. Set out all necessary items, including any pipettors and tips needed, a portable detection monitor, extra gloves, and a cell house (see Fig. A.2B.2, panel A).

Work involving this much radioactivity should be done behind a Plexiglas shield at least ¾ in. (2 cm) thick; the addition of a layer of lead to the outside lower section of this shield to stop Bremsstrahlung radiation is also needed. If one shield can be dedicated to this purpose at a specific location, a sheet of lead several centimeters thick can be permanently screwed to the Plexiglas (as shown in Fig. A.2B.2, panel B); however, this lead makes the shield extremely heavy and therefore less than portable. If space constraints do not permit the existence of such a permanent labeling station, a layer or two of lead foil can be taped temporarily to the outside of the Plexiglas shield.

Again, each worker should take care to shield not only him or herself, but bystanders on all sides. Handling of label should be done away from the central laboratory if possible to take maximum advantage of distance as an additional form of shielding. It is also advisable not to perform such experiments in a tissue culture room or any other room that is designed for a purpose vital to the whole laboratory. An accident involving this much ^{32}P would seriously inconvenience future work in the area, if not make it altogether uninhabitable! If care is taken to minimize the amount of time the dish

PCU IAS CENTRAL UNIVERSITY LIBRARY

of cells is open when adding the label, use of a controlled air hood to prevent fungal or bacterial contamination of the cells should not be necessary.

Once the label has been added to the dishes of cells, they will also need to be shielded for transport to and from the incubator and other work areas. Plexiglas boxes that are open at one end (for insertion of the dishes) and have a handle on top (for safe carrying) make ideal "cell houses" (see Figure A.2B.2, panel A). A Plexiglas door that slides into grooves at the open end is important to prevent dishes from sliding out if the box is tilted at all during transport. If this door is only two-thirds the height of the house wall, the open slot thus created will allow equilibration of the CO_2 level within the house with that in the incubator. Obviously, this slot will also allow a substantial stream of radiation to pass out of the cell house, so the house should be carried and placed in the incubator with its door facing away from the worker (and others)!

Following incubation with label and any treatments or other experimental manipulations, the cells are usually lysed in some type of detergent buffer. It is probably during this lysis procedure that a worker's hands will receive their greatest exposure to radiation, because it is necessary to directly handle the dishes over a period of several minutes. It is therefore very important to streamline this procedure and use any shielding whenever possible. If the cell lysates must be made at 4°C, as

B. C. U. „M. EMINESCU" IAŞI
CHIMIE

BCU IAŞI / CENTRAL UNIVERSITY LIBRARY

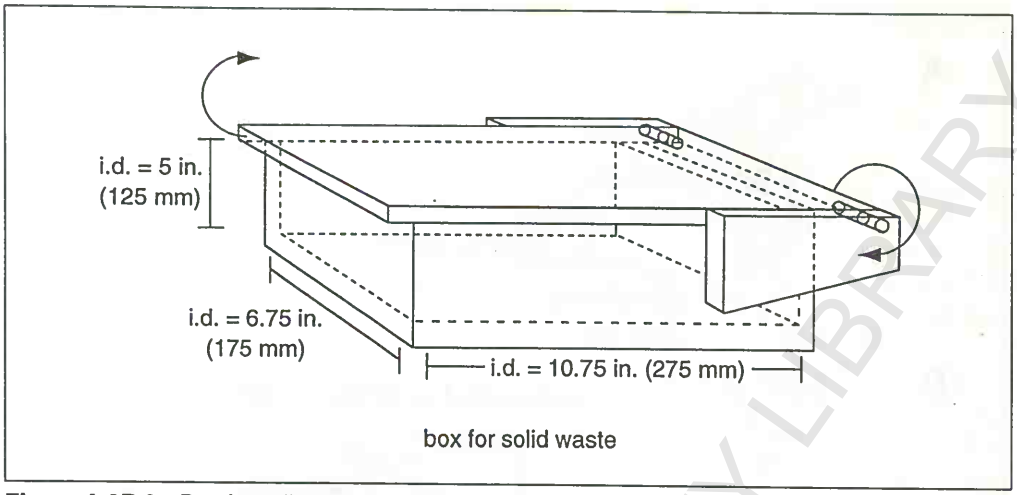

Figure A.2B.3 Box for solid waste collection made of 0.5-in. Plexiglas. Abbreviation: i.d., interior dimension.

required by most protocols, working on a bench in a cold room is preferable to placing the dishes on a slippery bed of ice. In either case, make the lysate using the same sort of shielding (with lead if necessary) that was used when initially adding the label. Pipet the labeling medium and any solution used to rinse unincorporated radioactivity from the cells into a small tube held in a solid Plexiglas holder (shown in Fig. A.2B.1, panel C). The contents of this tube can later be poured into the appropriate liquid waste receptacle. If possible, it is a good practice to keep this high-specific-activity ^{32}P liquid waste separate from the lower-activity waste generated in other procedures so that it can be removed from the laboratory as soon as possible following the experiment. If it is necessary to store it in the laboratory for any time, the shielding for the waste container should also include a layer of lead.

The solid waste generated in the lysis part of these experiments (pipet tips, disposable pipets, cell scrapers, and dishes) is very hot and should be placed immediately into some sort of shielded container to avoid further exposure of the hands. A Plexiglas box similar in design to that in Figure A.2B.3 is convenient; placed to the side of the shield and lined with a plastic bag, it will safely hold all radioactive waste during the experiment and is light enough to be easily carried to the main laboratory waste container where the plastic bag (and its contents) can be dumped after the experiment is done. If the lid of the box protrudes an inch or so over the front wall, it can be lifted using the back of a hand, thus decreasing the possibility of contaminating it with hot gloves.

When scraping the cell lysates from the dishes, it is good practice to add them to microcentrifuge tubes that are shielded in a solid Plexiglas rack; this will help to further reduce the exposure to which the hands are subjected. At this point, the lysates are usually centrifuged at high speed (>10,000 × *g*) to clear them of unsolubilized cell material. Use screw-cap tubes for this clarification step, as these will contain the labeled lysate more securely than flip-top tubes, which may open during centrifugation. No matter what type of tube is used, the rotor of the centrifuge often becomes contaminated, most probably due to tiny drops of lysate (aerosol) initially present on the rim of the tubes that are spun off during centrifugation. Monitor the rotor and wipe it out after each use.

The amount of ^{32}P taken up by cells during the incubation period varies considerably, depending on the growth state of the culture as well as on the cell type and its sensitivity to radiation. This makes it difficult to predict the percentage of the radioactivity initially added to the cells that is incorporated into the cell lysate; however, this figure probably does not exceed 10%. Thus, the amount of radioactivity being handled decreases dramatically after lysis, making effective shielding much simpler. However, at least ten times more radioactivity than is usual in other sorts of experiments is still involved! It is easy to determine if the shielding is adequate—just use both β and γ portable monitors to measure the radiation coming through it. Again, be sure to check that people working nearby (including those across the bench) are also adequately shielded. It is

sometimes necessary to construct a sort of cage of Plexiglas shields around the ice bucket that contains the lysates.

At the end of the day or the experiment, it may be necessary to store radioactive samples; in some experiments, it may be desirable to save the cell lysates. These very hot samples are best stored in tubes placed in solid Plexiglas racks that can then be put into Plexiglas boxes (see Fig. A.2B.2, panel C). Such boxes may be of similar construction to the cell houses described above; however, they should have a door that completely covers the opening. Be sure to check the γ radiation coming through these layers and add lead outside if necessary.

Working with ^{33}P

Using ^{33}P-labeled nucleotides to label nucleic acid probes or proteins

Several of the major companies that manufacture radiolabeled biological molecules have recently introduced nucleotides labeled with ^{33}P (both α- and γ-labeled forms). ^{33}P offers a clear advantage over ^{32}P with respect to ease of handling, because the energy of the β particles it releases lies between that of ^{35}S and ^{32}P and thus its use does not require as many layers of Plexiglas and lead shielding as for ^{32}P. In fact, the β radiation emitted can barely penetrate through gloves and the surface layer of skin, so the hazard associated with exposure to even millicurie amounts of ^{33}P is thought to be insignificant (as reported in the DuPont NEN product brochure). Gel bands visualized on autoradiographs of ^{33}P-labeled compounds are sharper than bands labeled with ^{32}P because the lower-energy β radiation does not have the scatter associated with that from ^{32}P. The half-life of ^{33}P is also longer (25 days compared to 14 days for ^{32}P). Despite its higher cost, these features have led many researchers to choose ^{33}P-labeled nucleotides for use in experiments such as band/gel shift assays where discrimination of closely-spaced gel bands is important.

The best way to determine what degree of shielding is needed when using ^{33}P is to monitor the source using a portable β monitor and add layers of Plexiglas as necessary.

Working with ^{125}I

Using ^{125}I to detect immune complexes (Western blots)

^{125}I that is covalently attached to a molecule such as staphylococcal protein A is not volatile and therefore is much less hazardous than the unbound or free form. Most institutions do not insist that work with bound ^{125}I be performed in a hood, but shielding of the γ radiation is still necessary. Lead is a good high-density material for stopping these γ rays; its drawbacks are its weight and opacity. Commercially available shields for ^{125}I are made of lead-impregnated Plexiglas—though heavy, these are at least see-through. Alternatively, a piece of lead foil may be taped to a structural support, although this arrangement does not provide shielding for the head as a worker peers over the lead!

Incubations of the membrane or blot with the [^{125}I] protein A solution and subsequent washes are usually done on a shaker. For shielding during these steps, a piece of lead foil may simply be wrapped around the container. Solutions of ^{125}I can be conveniently stored for repeated use in a rack placed in a lead box.

Using ^{125}I to label proteins or peptides in vitro

Any experiments that call for the use of free, unbound ^{125}I should be done behind a shield in a hood that contains a charcoal filter to absorb the volatile iodine. Most institutions require that such experiments be done in a special hot lab to which access is limited. Ingested or inhaled iodine is concentrated in the thyroid; a portable γ monitor should therefore be used to scan the neck and throat before beginning and after completing each experiment. Similar scans should routinely be performed on all members of any laboratory in which unbound iodine is used.

DEALING WITH ACCIDENTS

Despite the best intentions and utmost caution, accidents happen! Accidents involving spills of radioactivity are particularly insidious because they can be virtually undetectable yet pose a significant threat to laboratory workers. For this reason it is best to foster a community spirit in any laboratory where radioisotopes are routinely used—a sense of cooperativity that extends from shielding each other properly to helping each other clean up when such accidents occur.

The specific measures to be taken following an accident involving radioactivity naturally depend on the type and amount of the isotope involved, the chemical or biological hazards of the material it is associated with, and the physical parameters of the spill (i.e., where and onto what the isotope was "misplaced"). However, following any accident there are several immediate steps that should be taken:

BOU MED CENTRAL UNIVERSITY LIBRARY

1. Alert coworkers as well as Radiation Safety personnel to the fact that there has been an accident. This will give them the opportunity to shield themselves if necessary—and to help clean up as well!

2. Restrict access to and away from the site of the accident to ensure that any uncontained radioactive material is not spread around the laboratory. When leaving the site be sure to monitor the bottoms of the shoes as well as the rest of the body.

3. Take care of all contaminated personnel first, evacuating others if necessary. If anyone's skin is contaminated, first use a portable monitor to identify specific areas of contamination. Then wipe these areas with a damp tissue to remove as much surface radioactivity as possible. Try to scrub only small areas at a time to keep the contamination localized. If the contamination is not easily removed with paper tissues, try a sponge or an abrasive pad, but be careful not to break the skin! Sometimes soaking is required: do this only after all easily removed contamination is gone and keep the soaked area to a minimum. Contaminated strands of hair can be washed (or perhaps a new hairstyle may be in order).

4. When attempting to clean any contaminated equipment, floors, benches, etc., begin by soaking up any visible radioactive liquid with an absorbent material. Use a small amount of soap and water to clean the contaminated area, keeping the area wiped each time to a minimum to avoid smearing the contamination over an even greater surface. Many surfaces prove resistant to even Herculean cleaning efforts; in these instances the best that can be done is to remove all contamination possible and then shield whatever is left until the radioactivity decays sufficiently for safety.

Centrifuges and Rotors

Centrifugation runs described in this book usually specify a relative centrifugal force (RCF; measured in $\times g$), corresponding to a speed (in rpm) for a particular centrifuge and rotor model. As available equipment will vary from laboratory to laboratory, the investigator must be able to adapt these specifications to other centrifuges and rotors.

The relationship between RCF and speed (rpm) is determined by the following equation:

$$RCF = 1.12r\,(rpm/1000)^2$$

where r is the rotating radius between the particle being centrifuged and the axis of rotation. In most cases, an accurate conversion from speed to relative centrifugal force (or vice versa) can be obtained using the maximum value of r—or r_{max}—equal to the distance between the axis of rotation and the bottom of the centrifuge tube as it sits in the well or bucket of the rotor.

Table A.2C.1 provides r_{max} values for commonly used rotors manufactured by Du Pont (Sorvall), Beckman, Fisher, and IEC. There are situations (e.g., where an adapter is used to fit a smaller tube into a larger rotor well) where r_{max} will not accurately represent the effective rotating radius. In such cases, the manual for the rotor should be consulted to obtain the appropriate value of r.

As an alternative to use of the above equation, the nomograms in Figures A.2C.1 and A.2C.2 make it possible to determine the RCF where speed and r_{max} are known, or the speed where RCF and r_{max} are known. This is done by aligning a ruler across the two known values and reading the unknown value at the point where the ruler crosses the remaining column. Figure A.2C.1 should be used for centrifuge runs <21,000 rpm, while Figure A.2C.2 should be used for faster spins.

NOTE: In this manual, for spins involving microcentrifuges built to the Eppendorf standard, a shortened style of reference including only the speed (in rpm) is used. All of these instruments have approximately the same rotating radius; hence the same speed will yield the same RCF value from machine to machine. Microcentrifuge spins may also be described as at "top speed" or "maximum speed," meaning 12,000 to 14,000 rpm, which is the maximum speed for all Eppendorf-type microcentrifuges.

CAUTION: Do not exceed maximum rotor speed! For Beckman ultracentrifuges, the maximum speed for each rotor is denoted by its name, e.g., the maximum speed of the Beckman VTi 80 rotor is 80,000 rpm. This speed refers only to centrifugation of solutions below a particular allowed density, which differs among rotors (see user manual). For centrifugation of high-density solutions, rotor maximum speed can be determined as: reduced rpm = $rpm_{max}(A/B)^{1/2}$, where A = allowed density and B = density of solution. A = 1.7 g/ml for several vertical rotors (including VTi 80 and VTi 50), and 1.2 g/ml for several swinging-bucket rotors (including SW 55 Ti, 28, 28.1, 40 Ti, and 50.1). For gradients using heavy salts such as CsCl, particularly at low temperatures, maximum rpm should be reduced to prevent precipitation (see user manual).

IEC Clinical centrifuge with 4-place swinging-bucket rotor	155
IEC general-purpose centrifuge models HN, HN-SII, and Centra-4	—[c]

[a]Sorvall centrifuges and rotors are a product of Du Pont Company Medical Products, Beckman centrifuges are a product of Beckman Instruments, IEC centrifuges are a product of International Equipment Co., Clay Adams Dynac centrifuges are a product of Becton Dickinson Labware, and Fisher centrifuges are a product of Fisher Scientific. For ordering information see *SUPPLIERS APPENDIX*.

[b]These instruments are often loosely referred to as "clinical," "tabletop," or "low-speed" centrifuges.

[c]These instruments accept a wide range of trunnion-ring rotors with variable rotating radii, as well as fixed-angle and swinging-bucket rotors that in turn accept a variety of adapters making it possible to spin different numbers tubes of various sizes. For instance, the commonly used IEC 958 trunnion-ring rotor may be adjusted to radii ranging from 137 to 181 mm, depending on the trunnion-ring chosen. It is therefore necessary to consult the manual for the specific system being used to obtain an accurate speed to RCF conversion.

BCU ASTON CENTRAL UNIVERSITY LIBRARY

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Standard Laboratory Equipment

Special equipment is also itemized in the materials list of each protocol. We have not attempted to list all items required for each procedure, but rather have noted those items that might not be readily available in the laboratory or that require special preparation. Listed below are standard pieces of equipment in the modern biochemistry laboratory, i.e., items used extensively in this manual and thus not included in the individual materials lists. See *SUPPLIERS APPENDIX* for contact information for commercial vendors of laboratory equipment.

Autoclave

Balances, analytical and preparative.

Bench protectors, plastic-backed (including "blue pads.")

Centrifuges low-speed (6,000 rpm) and high-speed (20,000 rpm) refrigerated centrifuges and an ultracentrifuge (20,000 to 80,000 rpm) are required for many procedures. At least one microcentrifuge that holds standard 0.5- and 1.5-ml microcentrifuge tubes is essential. It is also useful to have a tabletop swinging-bucket centrifuge with adapters for spinning 96-well microtiter plates.

NOTE: *Centrifuge speeds are provided as × g or as rpm (with example rotor models) throughout the manual. Readers should consult the nomogram in APPENDIX 2C to convert these speeds to their own rotor models.*

Cold room (4°C) or cold box.

Computer (PC or Macintosh) and printer

Containers assortment of plastic and glass dishes for gel and membrane washes.

Darkroom and developing tanks or X-Omat automatic X-ray film developer (Kodak).

Dry ice

Filtration apparatus for collecting acid precipitates on nitrocellulose filters or membrane.

Flasks, glass (e.g., Erlenmeyer, beveled shaker).

Fraction collector

Freezers for –20° and –70°C incubation and storage.

Geiger counter

Gel dryer

Gel electrophoresis equipment at least one full-size horizontal apparatus and one horizontal minigel apparatus, one vertical full-size and minigel apparatus for polyacrylamide protein gels, and specialized equipment for two-dimensional protein gels as required.

Heating blocks thermostat-controlled metal heating blocks that hold test tubes and/or microcentrifuge tubes are very convenient for carrying out enzymatic reactions.

Heat-sealable plastic bags and apparatus

Hoods, chemical and microbiological.

Ice maker

Incubator (37°C) for growing bacteria. We recommend an incubator large enough to hold a "tissue culture" roller drum that can be used to grow 5-ml cultures in standard 18 × 150–mm test tubes. A convenient and durable tube roller is made by New Brunswick Scientific.

Incubator/shaker(s) an enclosed shaker (such as the New Brunswick Controlled Environment Incubator Shaker) that can spin 4-liter flasks is essential for growing 1-liter *E. coli* cultures. A rotary shaking water bath (New Brunswick R76) is useful for growing smaller cultures in flasks.

Light box for viewing gels and autoradiograms.

Liquid nitrogen

Lyophilizers

Magnetic stirrers (with heater is useful) and stir–bars.

Microcentrifuge, Eppendorf-type, maximum speed 12,000 to 14,000 rpm.

Microcentrifuge tubes, 1.5-ml and 0.5-ml.

Microwave oven to melt agar and agarose.

Mortar and pestle

Paper cutter large size, for 46 × 57–cm Whatman paper sheets.

Paper towels

Parafilm

Pasteur pipets and bulbs

pH meter

pH paper

Pipettors that use disposable tips and dispense 1 to 1000 µl. It is best to have a set for

Copyright © 1995 by John Wiley & Sons, Inc.

BOU IASI / CENTRAL UNIVERSITY LIBRARY

each full-time researcher, and sets dedicated for radioactive experiments.

Plastic wrap (e.g., Saran Wrap).

Polaroid camera and UV transilluminator for taking photographs of stained gels.

Policemen, rubber or plastic

Power supplies 300-volt power supplies are sufficient for polyacrylamide gels; a 2000- to 3000-volt power supply is needed for some applications.

Racks, to hold test tubes and microcentrifuge tubes.

Radiation shield (Lucite or Plexiglas).

Radioactive waste containers, for liquid and solid waste.

Refrigerator, 4°C.

Safety glasses

Scalpels and blades

Scintillation counter

Scissors

Seal-A-Meal bag sealer or equivalent.

Shakers, orbital and platform, room temperature or 37°C.

Spectrophotometer UV and visible.

Speedvac evaporator (Savant).

Tissue culture equipment CO_2 incubator, phase contrast microscope, liquid nitrogen storage container, and laminar flow hood.

UV light sources, long- and short-wave, stationary or hand-held.

Vortex mixers

Water baths at least two with 80°C capacity.

Water purification equipment such as Milli-Q system (Millipore) or its equivalent.

X-ray film cassettes and intensifying screens

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Commonly Used Reagents

BUFFERS AND STOCK SOLUTIONS

This collection describes the preparation of buffers and reagents used in the manipulation of proteins (see Table A.2E.1). When preparing solutions, use water purified using a Milli-Q apparatus (Millipore) or equivalent and reagents of the highest grade available. Sterilization—by filtration through a 0.22-μm filter—is recommended for most applications.

CAUTION: *Handle strong acids and bases carefully.*

Ammonium acetate, 10 M

Dissolve 385.4 g ammonium acetate in 150 ml H_2O
Add H_2O to 500 ml

Dithiothreitol (DTT), 1 M

Dissolve 15.45 g DTT in 100 ml H_2O
Store at –20°C

EDTA (ethylenediamine tetraacetic acid), 0.5 M (pH 8.0)

Dissolve 186.1 g $Na_2EDTA{\cdot}2H_2O$ in 700 ml H_2O
Adjust pH to 8.0 with 10 M NaOH (~50 ml)
Add H_2O to 1 liter

Begin titrating before the sample is completely dissolved. EDTA, even in the disodium salt form, is difficult to dissolve at this concentration unless the pH is increased to between 7 and 8.

Ethidium bromide, 10 mg/ml

Dissolve 0.2 g ethidium bromide in 20 ml H_2O
Mix well and store at 4°C in dark

CAUTION: *Ethidium bromide is a mutagen and must be handled carefully.*

BOSTON UNIVERSITY CENTRAL LIBRARY

HCl, 1 M

Mix in the following order:
914.1 ml H_2O
85.9 ml concentrated HCl

KCl, 1 M

74.6 g KCl
H_2O to 1 liter

$MgCl_2$, 1 M

20.3 g $MgCl_2 \cdot 6H_2O$
H_2O to 100 ml

$MgSO_4$, 1 M

24.6 g $MgSO_4 \cdot 7H_2O$
H_2O to 100 ml

NaCl, 5 M

292 g NaCl
H_2O to 1 liter

NaOH, 10 M

Mix in the following order:
476 ml H_2O
524 ml 50% (v/v) NaOH
Alternatively:
Dissolve 400 g NaOH in 450 ml H_2O
Add H_2O to 1 liter

Phenol, buffered

8-hydroxyquinoline
Liquefied phenol, redistilled
50 mM Tris base (unadjusted pH ~10.5)
50 mM Tris·Cl, pH 8.0 (see recipe)
TE buffer, pH 8.0 (see recipe)

Add 0.5 g of 8-hydroxyquinoline to a 2-liter glass beaker containing a stir bar. Gently pour in 500 ml of liquefied phenol or melted crystals of redistilled phenol (melted in a water bath at 65°C). The phenol will turn yellow due to the 8-hydroxyquinoline, which is added as an antioxidant. Add 500 ml of 50 mM Tris base. Cover the beaker with aluminum foil and stir 10 min at low speed with magnetic stirrer at room temperature. Let phases separate at room temperature. Gently decant the top (aqueous) phase into a suitable waste receptacle. Remove what cannot be decanted with a 25-ml glass pipet and a suction bulb. Add 500 ml of 50 mM Tris·Cl, pH 8.0. Repeat equilibration with 500 ml of 50 mM Tris·Cl, pH 8.0, twice. The pH of the phenol phase can be checked with indicator paper and should be 8.0. If it is not, repeat equilibration until this pH is obtained. Add 250 ml of 50 mM Tris·Cl, pH 8.0, or TE buffer, pH 8.0, and store at 4°C in brown glass bottles or clear glass bottles wrapped in aluminum foil.

Phenol prepared with 8-hydroxyquinoline as an antioxidant can be stored ≤2 months at 4°C.

Phenol must be redistilled before use, because oxidation products of phenol can damage and introduce breaks into nucleic acid chains. Redistilled phenol is commercially available. Regardless of the source, the phenol must be buffered before use.

CAUTION: *Phenol can cause severe burns to skin and damage clothing. Gloves, safety glasses, and a lab coat should be worn whenever working with phenol, and all manipulations should be carried out in a fume hood. A glass receptacle should be available exclusively for disposing of used phenol and chloroform.*

Phosphate-buffered saline (PBS)

10× stock solution, 1 liter:
80 g NaCl
2 g KCl
11.5 g $Na_2HPO_4 \cdot 7H_2O$
2 g KH_2PO_4

Working solution, pH ~7.3:
137 mM NaCl
2.7 mM KCl
4.3 mM $Na_2HPO_4 \cdot 7H_2O$
1.4 mM KH_2PO_4

Potassium acetate buffer, 0.1 M

Solution A: 11.55 ml glacial acetic acid/liter (0.2 M)
Solution B: 19.6 g potassium acetate ($KC_2H_3O_2$)/liter (0.2 M)

Referring to Table A.2E.2 for desired pH, mix the indicated volumes of solutions A and B, then dilute with H_2O to 100 ml.

This may be made as a 5- or 10-fold concentrate by scaling up the amount of potassium acetate in the same volume. Acetate buffers show concentration-dependent pH changes, so check concentrate pH by diluting an aliquot to the final concentration.

To prepare buffers with pH intermediate between the points listed in Table A.2E.2, prepare closest higher pH, then titrate with solution A.

BOWLING GREEN STATE UNIVERSITY LIBRARY

Potassium phosphate buffer, 0.1 M

Solution A: 27.2 g KH_2PO_4 per liter (0.2 M)
Solution B: 45.6 g $K_2HPO_4 \cdot 3H_2O$ per liter (0.2 M)

Referring to Table A.2E.3 for desired pH, mix the indicated volumes of solutions A and B, then dilute with H_2O to 200 ml.

This may be made as a 5- or 10-fold concentrate by scaling up the amount of potassium phosphate in the same volume. Phosphate buffers show concentration-dependent pH changes, so check concentrate pH by diluting an aliquot to the final concentration.

SDS, 20%

Dissolve 20 g SDS (sodium dodecyl sulfate or sodium lauryl sulfate) in H_2O to 100 ml total with stirring (it may be necessary to heat the solution slightly to fully dissolve the powder). Filter sterilize using a 0.45-μm filter.

Sodium acetate, 3 M

Dissolve 408 g sodium acetate·$3H_2O$ in 800 ml H_2O
Add H_2O to 1 liter
Adjust pH to 4.8 or 5.2 (as desired) with 3 M acetic acid

Sodium acetate buffer, 0.1 M

Solution A: 11.55 ml glacial acetic acid/liter (0.2 M)
Solution B: 27.2 g sodium acetate ($NaC_2H_3O_2 \cdot 3H_2O$)/liter (0.2 M)

Referring to Table A.2E.2 for desired pH, mix the indicated volumes of solutions A and B, then dilute with H_2O to 100 ml. (See Potassium acetate buffer recipe for further details.)

Sodium phosphate buffer, 0.1 M

Solution A: 27.6 g $NaH_2PO_4 \cdot H_2O$ per liter (0.2 M)
Solution B: 53.65 g $Na_2HPO_4 \cdot 7H_2O$ per liter (0.2 M)

Referring to Table A.2E.3 for desired pH, mix the indicated volumes of solutions A and B, then dilute with H_2O to 200 ml. (See Potassium phosphate buffer recipe for further details.)

SSC (sodium chloride/sodium citrate), 20×

3 M NaCl (175 g/liter)
0.3 M Na_3citrate·$2H_2O$ (88 g/liter)
Adjust pH to 7.0 with 1 M HCl

TAE (Tris/acetate/EDTA) electrophoresis buffer

50× stock solution:
242 g Tris base
57.1 ml glacial acetic acid
37.2 g $Na_2EDTA \cdot 2H_2O$
H_2O to 1 liter

Working solution, pH ~8.5:
40 mM Tris·acetate
2 mM $Na_2EDTA \cdot 2H_2O$

TBE (Tris/borate/EDTA) electrophoresis buffer

10× stock solution, 1 liter:
108 g Tris base (890 mM)
55 g boric acid (890 mM)
40 ml 0.5 M EDTA, pH 8.0 (see recipe; 20 mM)

TE buffer

10 mM Tris·Cl, pH 7.4, 7.5, or 8.0 (or other pH; see recipe)
1 mM EDTA, pH 8.0

BCU IASI / CENTRALA UNIVERSITY LIBRARY

Tris·Cl [tris(hydroxymethyl)aminomethane], 1 M

Dissolve 121 g Tris base in 800 ml H_2O
Adjust to desired pH with concentrated HCl
Mix and add H_2O to 1 liter

NOTE: *The pH of Tris buffers changes significantly with temperature, decreasing approximately 0.028 pH units per 1°C. Tris-buffered solutions should be adjusted to the desired pH at the temperature at which they will be used. Because the pK_a of Tris is 8.08, Tris should not be used as a buffer below pH ~7.2 or above pH ~9.0.*

Use of Protein Folding Reagents

DENATURANTS

Chemical agents that denature proteins are used to extract proteins from inclusion bodies as well as to study the conformation of purified proteins (Pace, 1986). The most common denaturants are guanidine hydrochloride (guanidine·HCl) and urea. These reagents and methods for their purification are described in this section.

Guanidine Hydrochloride

High-purity guanidine·HCl (also referred to as guanidinium chloride) can be purchased from several vendors as a crystalline solid or concentrated solution (usually 8 M) in water. Because dissolution of the salt is an endothermic process, when preparing concentrated solutions from the solid salt it is convenient to heat the mixture (in a glass container) in a domestic microwave oven. When the best grades of commercial guanidine·HCl (>99% pure) are used, a 6 M solution will be clear and colorless. Concentrated solutions made from practical-grade guanidine·HCl (usually 80% to 90% cheaper) may appear slightly hazy and be colored light brown. For large-scale preparative work, where the purchase of sufficient high-purity reagent would be prohibitive, solutions of practical-grade guanidine·HCl can be cleaned up adequately by filtration with 0.45- to 0.5-μm filters followed by decolorization with activated charcoal. Other applications, such as folding experiments (especially those involving spectroscopic monitoring), require higher-quality reagent; in such cases it is necessary to recrystallize the salt or purchase the ultrapure grade. Methods for purifying guanidine·HCl by recrystallization have been described by Nozaki (1972).

Because guanidine·HCl is hydroscopic, for critical studies, such as conformational analysis, accurate measurements of molarity should be made using a refractometer (e.g., the Abbe-3L refractometer from Milton Roy; see *SUPPLIERS APPENDIX*). Using Table A.3A.1 as a guideline for quantities, guanidine·HCl and water (or buffer) can be weighed in a container to give the approximate molarities indicated. A table of the refractive indexes of guanidine·HCl solutions from 0.057 M to 8.51 M (in increments of ~0.06 M) at 25°C is provided by Nozaki (1972).

There have been no reports, at least to the author's knowledge, of specific chemical modification of proteins resulting from exposure to guanidine·HCl or the contaminants found in the commercially purchased forms. However, the common contaminant ammeline, which is characterized by strong UV absorbance, may inhibit certain enzymes (Nozaki and Tanford, 1967; Nozaki, 1972, and references therein).

Guanidine·HCl solutions are stable at room temperature for several days (for longer periods, store at 4°C). Solutions are stable over normal working pH ranges—i.e., pH 2.0 to 10.5. At alkaline pH (>11), biguanidine may form (Nozaki and Tanford, 1967).

Urea

High-purity (>99%) urea can be purchased from many different vendors and is only approximately twice as expensive as practical-grade material. Urea solutions slowly decompose to form ammonium cyanate, which reacts readily with various protein functional groups. An 8 M solution of urea incubated at room temperature >pH 7.0 will contain ~4 mM cyanate after 7 days and ~20 mM at equilibrium.

Table A.3A.1 Properties of Urea and Guanidine·HCl Solutions

Property	Urea	Guanidine·HCl
Molecular weight	60.06	95.53
Solubility (at 25°C)[a]	10.49 M	8.54 M
Melting point (°C)	133-137	186.5-188.5
A_{260} (6 M in water)	<0.06	<0.03

[a]Solubilities at 5°C: urea, ~8 M; guanidine·HCl, ≥8 M.

[a]Given weight of reagent added to 10 g water to generate a solution of the indicated molarity.

[b]The final volume resulting from the addition of indicated amount of reagent to 10 g water was determined using the specific gravity of the solution calculated as described by Kawahara and Tanford (1966). Volume estimates can also be made by assuming 1 g of urea or guanidine·HCl increases the volume by 0.763 ml (i.e., the partial specific volume = 0.763). The density of water at 25°C is 0.9971 (10 g = 10.029 ml).

[c]Weight of reagent made up with water or buffer to a final volume of 1 liter.

Formation of cyanate occurs faster at higher temperatures (e.g., equilibrium is reached in 30 min at 100°C), and it may therefore be helpful to keep the solution cold. Cyanate reacts readily with the amino, sulfhydryl, imidazole, tyrosyl, and carboxyl groups of proteins. Only the reaction with amino groups results in stable products at alkaline pH (Means and Feeney, 1971). The carbamylation of α-amino (N-terminal) and ε-amino groups (lysine side chains) results in the formation of a neutral product, homocitrulline; hence there is a loss of one positive charge for each residue modified.

The standard method for removing cyanate is deionization using a mixed-bed ion-exchange resin (e.g., AG 501-X8, Bio-Rad; see *SUPPLIERS APPENDIX*). The batch method (adding resin to the solution, incubating, then filtering) is recommended for volumes <1 liter, whereas the column method (using resin packed in a chromatography column) is best for larger volumes (see Bio-Rad Bulletin 1825 and *UNIT 8.2*). Cyanate removal can be monitored by determining the solution conductivity; there are also simple specific assays available (Means and Feeney, 1972). For a detailed purification method, involving both recrystallization and deionization, see Prakash et al. (1981). Cyanate can also be removed by acidification to pH 2 with HCl, followed by a 1-hr incubation during which the cyanate breaks down to carbon dioxide and ammonium ions, and neutralization with Tris base. The solution can then be used as is.

For most applications it is recommended that solutions be made with ultrapure urea and used within 24 hr. A scavenger should be included to react with slowly forming cyanate; buffers containing primary amines, such as Tris and glycine, are suitable for this purpose. It should be noted that urea may increase the measured pH of aqueous solutions (see Bull et al., 1964).

As with guanidine·HCl, refractometry can be used to accurately determine the concentration of solutions, although solutions prepared by weight (Table A.3A.2) are normally accurate enough for most applications (Pace, 1986).

Effectiveness

According to Pace (1986) and references therein, guanidine·HCl is generally 1.5 to 2.5 times more effective per mole as a protein denaturant than urea.

Other Reagents

Guanidine thiocyanate is another denaturant of interest that is often used to elute proteins from immunoaffinity columns. Although guanidine thiocyanate is rarely used in preparative folding of recombinant proteins or in conformational analysis of proteins in general, it is

Table A.3A.3 Reduced and Oxidized Sulfhydryl Reagents

Reagent	MW[a]	MP (°C)	Absorbance (nm) (liter/mol/cm)[e]	SH[f] pK_a	E'_o (mV)[g]
GSH	307.33	192-195	260 (5.8) 280 (2.3)	8.63 (α) 9.45 (β)	–240
GSSG	612.63	178	250 (342) 260 (271) 280 (111) 300 (30)	—	
2-ME[b]	78.13	—	>260 (≈ 0, if pure)	9.5	
HED[c]	154.25	25-27	245 λ_{max} (380) 260 (310) 280 (200)	—	
DTT	154.25	42-44	>270 (≈ 0)	8.3 9.5	–330
Oxidized DTT[d]	152.20	132	283 λ_{max} (273) 310 (110)	—	

[a]Abbreviations: DTT, dithiothreitol; GSH, reduced glutathione (γ-L-glutamyl-L-cysteinylglycine, anionic thiol); GSSG, oxidized glutathione; HED, 2-hydroxyethyl disulfide; MP, melting point; MW, molecular weight.

[b]Pure liquid is 14.3 M (density = 1.114 g/ml) with a boiling point of 157° – 158°C.

[c]Liquid is 8.2 M (density = 1.261 g /ml).

[d]Oxidized DTT (dihydroxy-1,2-dithiane) can be prepared from DTT by oxidation with ferricyanide (Cleland, 1964). Commercial material can be purified according to Creighton (1984).

[e]The values in parenthesis are the molar absorbencies at the wavelengths indicated.

[f]In amino thiols, the pK_a of the amine and thiol groups overlap; relevant pK_a's are indicated as α and β.

[g]The standard redox potential (at pH 7, 25°C); refers to the reduction potential for thiol-disulfide pairs: $2RSH = R\text{-}S\text{-}S\text{-}R + 2H^{++} + 2e^-$. Note that the lower the E'_o, the stronger the reductant—e.g., DTT is a better reductant than GSH.

2.5 to 3.5 times more effective than guanidine·HCl, and is available (albeit expensive) in high purity.

Other chaotropic reagents, mainly inorganic salts, are briefly reviewed and referenced in the Commentary section of *UNIT 6.3*. As there are few (if any) reports in the literature regarding the use of these reagents in solubilizing inclusion bodies, detailed discussion of their properties is not included. Future updates of this section will, however, address any important new reagents.

SULFHYDRYL REAGENTS AND OXIDO-SHUFFLING SYSTEMS

Sulfhydryl reagents (reducing agents) are used to prevent the oxidation of protein thiol groups. When proteins are extracted from inclusion bodies it is standard practice to include a reducing agent to prevent random oxidation of cysteine residues. Denatured proteins are subsequently folded under conditions that favor native disulfide formation. This process, referred to as oxidative folding, is carried out using "oxido-shuffling" (or oxidative regeneration) systems consisting of low-molecular-weight thiol/disulfide pairs (*UNITS 6.4 & 6.5*). The thiols and disulfides commonly used to reduce and oxidize recombinant proteins are shown in Table A.3A.3 and discussed in this section. Further details on these and other reducing agents are reviewed by Jocelyn (1987).

Dithiothreitol

Dithiothreitol (DTT), also known as Cleland's reagent, is the preferred reductant for protein reduction. DTT and its isomer dithioerythritol (DTE)—which can also be used as a protein reductant—have similar properties (and prices), except that at lower pH the former is more effective. This is because the pK_a values for DTE are higher (9.0 and 9.9) than those of DTT (8.3 and 9.5); hence, a higher pH is required to ionize DTE to its functional form.

BOSTON CENTRAL UNIVERSITY LIBRARY

The reducing capacity of both reagents increases greatly over the pH range 7 to 9.5. On the other hand, the reagents are quenched by acidification to <pH 3.0.

DTT is very soluble in water, and stock solutions of 0.1 to 0.2 M can be prepared and stored at 4°C for a day or so or frozen for longer periods. For critical work, solid DTT should be added to solvents and buffers immediately before use to achieve a final working concentration in the range of 1 to 20 mM. Because DTT complexes metal ions, EDTA is usually included in the reduction buffer. Air oxidation of DTT solution can be monitored by measuring the increase in absorbance at 283 nm (see Table A.3A.3).

2-Mercaptoethanol

2-Mercaptoethanol (2-ME) is also commonly used as a protein reducing agent. 2-ME is a volatile liquid that should be stored at 4°C and dispensed under a fume hood. A 100-mM stock solution of 2-ME can be made by diluting 6.99 ml of the reagent with solvent to 1 liter. 2-ME is not as potent a reductant as DTT, as it has a higher pK_a (Table A.3A.3), and is used in the concentration range of 5 to 100 mM. Air oxidation of 2-ME is best monitored by measuring the increase in absorbance at 260 nm (Table A.3A.3). Freshly opened bottles contain 0.1% to 6.7% of the oxidation product 2-hydroxyethyl disulfide (HED; Wetlaufer et al., 1987).

Glutathione

Glutathione (GSH) and its oxidized form GSSG are present in most cells at concentrations of 1 to 10 mM. In *E. coli*, the ratio of GSH/GSSG is 50:1 to 200:1 (Hwang et al., 1992), and the system is responsible for maintaining cytoplasmic proteins in a reduced state. GSH is not normally used as a reductant in analytical protein chemistry—its main utility is as a component of oxidative redox buffers (see discussion of Oxido-Shuffling Systems). However, GSH can be used to maintain unfolded protein in inclusion-body extracts in the reduced state (analogous to its role in vivo).

Stock solutions of 0.1 M GSH can be prepared in water or the reagent can be directly added to buffers. In either case the pH should be adjusted with base to the required pH.

Oxido-Shuffling Systems

The commonly used oxido-shuffling systems used in folding recombinant proteins are GSH/GSSG, 2-ME/HED, and DTT/oxidized DTT (for reviews, see Creighton, 1984, and Wetlaufer, 1984), which are shown in Table A.3A.3. All six reagents are commercially available (the scarcest, HED, can be obtained from Aldrich; see *SUPPLIERS APPENDIX*) and are normally used as purchased, without further purification.

Dialysis

Conventional dialysis separates small molecules from large molecules by allowing diffusion of only the small molecules through selectively permeable membranes. Dialysis is usually used to change the salt (small-molecule) composition of a macromolecule-containing solution. The solution to be dialyzed is placed in a sealed dialysis membrane and immersed in a selected buffer; small solute molecules then equilibrate between the sample and the dialysate. Concomitant with the movement of small solutes across the membrane, however, is the movement of solvent in the opposite direction. This can result in some sample dilution (usually <50%).

This section describes dialysis of large- and small-volume samples using cellulose membranes with pore sizes designed to exclude molecules above a selected molecular weight (Basic and Alternate Protocols). A Support Protocol describes preparation of membranes for dialysis.

LARGE-VOLUME DIALYSIS

BASIC PROTOCOL

This protocol describes the use of membranes, prepared using the support protocol, for dialysis of samples in large, easily handled volumes, typically 0.1 to 500 ml.

Materials

Dialysis membrane (see Support Protocol)
Clamps (Spectrapor Closures, Spectrum, or equivalent)
Macromolecule-containing sample to be dialyzed
Appropriate dialysis buffer

1. Remove dialysis membrane from ethanol storage solution and rinse with distilled water. Secure clamp to one end of the membrane or knot one end with double-knots.

   Always use gloves to handle the dialysis membrane because the membrane is susceptible to cellulolytic microorganisms.

   See support protocol for a discussion of commercially available membranes and preparation and storage procedures.

   Clamps are less likely to leak than knots, but either type of closure should be carefully tested as described in steps 2 and 3.

2. Fill membrane with water or buffer, hold the unclamped end closed, and squeeze membrane. A fine spray of liquid indicates a pinhole in the membrane; discard and try a new membrane.

   Pinholes are rare but cause traumatic sample loss. Hard squeezing will cause some liquid to seep from the bag; this is normal.

3. Replace the water or buffer in dialysis membrane with the macromolecule-containing sample and clamp the open end. Again, squeeze to check the integrity of the membrane and clamps.

   If dialyzing a concentrated or high-salt sample, leave some space in the clamped membrane; there will be a net flow of water into the sample, and if sufficient pressure builds up the membrane can burst.

4. Immerse dialysis membrane in a beaker or flask containing a large volume (relative to the sample) of the desired buffer. Dialyze at least 3 hr at the desired temperature with gentle stirring of the buffer.

   Dialysis rates are dependent on membrane pore size, sample viscosity, and ratio of membrane surface to sample volume. Temperature has little effect on dialysis rate, but

Copyright © 1995 by John Wiley & Sons, Inc.

BOURNS / CENTRAL UNIVERSITY LIBRARY

low temperatures (i.e., 4°C) are usually chosen to enhance macromolecule stability. Common salts will equilibrate across a 15,000-MWCO membrane (see Support Protocol) in ~3 hr with stirring.

Some compounds, especially detergents above their critical micelle concentration (CMC), dialyze very slowly.

5. Change dialysis buffer as necessary.

   Usually two to three dialysis buffer changes are sufficient. For example, when 100 mM Tris·Cl is removed from a protein for sequence analysis or other amino-reactive chemistry, two equilibriums against a 1000-fold volume excess of buffer will decrease the Tris concentration 10^6-fold, to 100 nM; three dialyses will decrease the concentration to 100 pM.

6. Remove dialysis membrane from the buffer. Hold the membrane vertically and remove excess buffer trapped in end of membrane outside upper clamp. Release upper clamp and remove the sample with a Pasteur pipet.

ALTERNATE PROTOCOL

SMALL-VOLUME DIALYSIS

For solution volumes less than ~100 µl, the use of dialysis membrane as described above can result in unacceptable sample loss. The method described below can easily dialyze volumes as small as 10 µl. The sample is held in a 0.5-ml microcentrifuge tube, with dialysis membrane covering the open end of the tube.

Additional Materials

0.5-ml microcentrifuge tube
Cork borer

1. Cut a hole in the cap of a 0.5-ml microcentrifuge tube using a cork borer. Be sure that there are no rough edges on the inside of the cap (which will be in contact with the dialysis membrane).

   The success of this protocol is dependent on a tight-fitting cap, so make sure the cap is well-seated. On the other hand, an excessively tight-fitting cap can rip the membrane when it is inserted. Sarstedt tubes work well.

   Alternatively, some researchers use a microcentrifuge tube without a cap. The sample is placed in the microcentrifuge tube, a dialysis membrane is placed over the top of the tube, and the membrane is secured with a rubber band. With this method, however, there is a risk that a small sample—e.g., 10 to 20 µl—may be lost around the edge of the tube.

2. Place sample in the microcentrifuge tube, cover tube opening with dialysis membrane, and snap on the tube cap in which a hole has been cut.

   This places a fair amount of stress on the dialysis membrane, so use a fairly thick membrane and make sure there are no rough edges on the cap.

3. To get the sample in contact with the dialysis membrane, *gently* centrifuge the microcentrifuge tube in an inverted position in a tabletop centrifuge.

4. Keep the tube inverted, immerse it in dialysis buffer, and anchor it so that it will remain inverted and immersed.

   This is easily done by inserting tubes in a styrofoam or foam sheet (e.g., Fisherbrand foam microcentrifuge tube rack) and placing the inverted tubes on the surface of the dialysis buffer.

5. Use a bent Pasteur pipet to blow out any air bubbles trapped under the cap to allow dialysis buffer to contact the membrane.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

This step is usually not necessary if the membrane/rubber band method is used (see step 1 annotation).

6. Stir the dialysis buffer and dialyze at an appropriate temperature for at least 3 hr (see Basic Protocol, step 4).

7. To recover the sample, remove microcentrifuge tube from the buffer and centrifuge briefly right-side-up.

Commercially available alternatives to this method include use of individual hollow-fiber filters from Spectrum (with sample capacities of 1 to 140 µl), and many different microdialysis machines, both single-sample and multisample (Spectrum, Cole-Parmer, Hoefer Pharmacia, and others).

SELECTION AND PREPARATION OF DIALYSIS MEMBRANE

SUPPORT PROTOCOL

Dialysis membranes are available in a number of thicknesses and pore sizes. Thicker membranes are tougher, but restrict solute flow and reach equilibrium more slowly. Pore size is defined by "molecular weight cutoff" (MWCO)—i.e., the size of the smallest particle that cannot penetrate the membrane. The MWCO designation should be used only as a very rough guide; if accurate MWCO information is required, it should be determined empirically (see Craig, 1967, for a discussion of parameters affecting MWCO). Knowledge of the precise MWCO is usually not required, however; it is necessary only to use a membrane with a pore size that is much smaller than the macromolecule of interest. For most plasmid and protein dialyses, a MWCO of 12,000 to 14,000 is appropriate, whereas a MWCO of 3500, 2000, or even 1000 is appropriate for peptides.

Most dialysis membranes are made of derivatives of cellulose. They come in a wide variety of MWCO values, ranging from 500 to 500,000, and also vary in cleanliness, sterility, and cost. Spectrum has the most impressive inventory. The least expensive membranes come dry on rolls; these contain glycerol to keep them flexible as well as residual sulfides and traces of heavy metals from their manufacture. If glycerol, sulfur compounds, or small amounts of heavy metals are problematic, cleaner membranes should be purchased or membranes should be prepared as described below. Protein dialysis should only be done with clean membranes.

Additional Materials

10 mM sodium bicarbonate
10 mM Na_2EDTA, pH 8.0
20% to 50% (v/v) ethanol

1. Remove membrane from the roll and cut into usable lengths (usually 8 to 12 in.).

Always use gloves to handle dialysis membrane, as it is susceptible to a number of cellulolytic microorganisms. Membrane is available as sheets or preformed tubing.

2. Wet membrane and boil it for several minutes in a large excess of 10 mM sodium bicarbonate.

3. Boil several minutes in 10 mM Na_2EDTA. Repeat.

Boiling speeds up the treatment process but is not necessary. A 30-min soak with some agitation can substitute for the boiling step.

4. Wash several times in distilled water.

5. Store at 4°C in 20% to 50% ethanol to prevent growth of cellulolytic microorganisms.

Alternatively, bacteriostatic agents (e.g., sodium azide or sodium cacodylate) may be used for storage; however, ethanol is preferred for ease and convenience.

Techniques for Mammalian Cell Tissue Culture

Tissue culture technology has found wide application in biological research. Monolayer cell cultures are utilized in cytogenetic, biochemical, and molecular laboratories for research as well as diagnostic studies. In most cases, cells or tissues must be grown in culture for days or weeks to obtain sufficient numbers of cells for analysis. Maintenance of cells in long-term culture requires strict adherence to aseptic technique to avoid contamination and potential loss of valuable cell lines. The first section of this appendix discusses basic principles of sterile technique.

An important factor influencing the growth of cells in culture is the choice of tissue culture medium. Many different recipes for tissue culture media are available and each laboratory must determine which medium best suits their needs. Individual laboratories may elect to use commercially prepared medium or prepare their own. Commercially available medium can be obtained as a sterile and ready-to-use liquid, in a concentrated liquid form, or in a powdered form. Besides providing nutrients for growing cells, medium is generally supplemented with antibiotics, fungicides, or both to inhibit contamination. The second section of this appendix discusses medium preparation.

As cells grown in monolayer reach confluency, they must be subcultured or passaged. Failure to subculture confluent cells results in reduced mitotic index and eventually in cell death. The first step in subculturing is to detach cells from the surface of the primary culture vessel by trypsinization or mechanical means. The resultant cell suspension is then subdivided, or reseeded, into fresh cultures. Secondary cultures are checked for growth, fed periodically, and may be subsequently subcultured to produce tertiary cultures, etc. The time between passaging cells varies with the cell line and depends on the growth rate.

The Basic Protocol describes subculturing of a monolayer culture grown in petri dishes or flasks. Support Protocols 1 to 4 describe freezing of monolayer cells, thawing and recovery of cells, counting cells using a hemacytometer, and preparing cells for transport. The Alternate Protocol describes freezing suspension cells.

STERILE TECHNIQUE

It is essential that sterile technique be maintained when working with cell cultures. Aseptic technique involves a number of precautions to protect both the cultured cells and the laboratory worker from infection. The laboratory worker must realize that cells handled in the lab are potentially infectious and should be handled with caution. Protective apparel such as gloves, lab coats or aprons, and eyewear should be worn when appropriate (Knutsen, 1991). Care should be taken when handling sharp objects such as needles, scissors, scalpel blades, and glass that could puncture the skin. Sterile disposable plastic supplies may be used to avoid the risk of broken or splintered glass (Rooney and Czepulkowski, 1992).

Frequently, specimens received in the laboratory are not sterile, and cultures prepared from these specimens may become contaminated with bacteria, fungus, or yeast. The presence of microorganisms can inhibit growth, kill cell cultures, or lead to inconsistencies in test results. The contaminants deplete nutrients in the medium and may produce substances that are toxic to cells. Antibiotics (penicillin, streptomycin, kanamycin, or gentamycin) and fungicides (amphotericin B or mycostatin) may be added to tissue

BOLTON CENTRAL UNIVERSITY LIBRARY

culture medium to combat potential contaminants (see Table A.3C.1). An antibiotic/antimycotic solution or lyophilized powder that contains penicillin, streptomycin, and amphotericin B is available from Sigma. The solution can be used to wash specimens prior to culture and can be added to medium used for tissue culture. Similar preparations are available from other suppliers.

All materials that come into direct contact with cultures must be sterile. Sterile disposable dishes, flasks, pipets, etc., can be obtained directly from manufacturers. Reusable glassware must be washed, rinsed thoroughly, then sterilized by autoclaving or by dry heat before reusing. With dry heat, glassware should be heated 90 min to 2 hr at 160°C to ensure sterility. Materials that may be damaged by very high temperatures can be autoclaved 20 min at 120°C and 15 psi. All media, reagents, and other solutions that come into contact with the cultures must also be sterile; medium may be obtained as a sterile liquid from the manufacturer, autoclaved if not heat-sensitive, or filter sterilized. Supplements can be added to media prior to filtration, or they can be added aseptically after filtration. Filters with 0.20- to 0.22-μm pore size should be used to remove small gram-negative bacteria from culture media and solutions.

Contamination can occur at any step in handling cultured cells. Care should be taken when pipetting media or other solutions for tissue culture. The necks of bottles and flasks, as well as the tips of the pipets, should be flamed before the pipet is introduced into the bottle. If the pipet tip comes into contact with the benchtop or any other nonsterile surface, it should be discarded and a fresh pipet obtained. Forceps and scissors used in tissue culture can be rapidly sterilized by dipping in 70% alcohol and flaming.

Although tissue culture work can be done on an open bench if aseptic methods are strictly enforced, many labs prefer to perform tissue culture work in a room or low-traffic area reserved specifically for that purpose. At the very least, biological safety cabinets are recommended to protect the cultures as well as the laboratory worker. In a laminar flow hood, the flow of air protects the work area from dust and contamination and acts as a barrier between the work surface and the worker. Many different styles of safety hoods are available and the laboratory should consider the types of samples being processed and the types of potential pathogenic exposure in making their selection. Manufacturer recommendations should be followed regarding routine maintenance checks on air flow and filters. For day-to-day use, the cabinet should be turned on for at least 5 min prior to beginning work. All work surfaces both inside and outside of the hood should be kept clean and disinfected daily and after each use.

Some safety cabinets are equipped with ultraviolet (UV) lights for decontamination of work surfaces. However, use of UV lamps is no longer recommended, as it is generally ineffective (Knutsen, 1991). UV lamps may produce a false sense of security as they maintain a visible blue glow long after their germicidal effectiveness is lost. Effectiveness diminishes over time as the glass tube gradually loses its ability to transmit short UV wavelengths, and it may also be reduced by dust on the glass tube, distance from the work surface, temperature, and air movement. Even when the UV output is adequate, the rays must directly strike a microorganism in order to kill it; bacteria or mold spores hidden below the surface of a material or outside the direct path of the rays will not be destroyed. Another rule of thumb is that anything that can be seen cannot be killed by UV. UV lamps will only destroy microorganisms such as bacteria, virus, and mold spores; they will not destroy insects or other large organisms (Westinghouse Electric Company, 1976). The current recommendation is that work surfaces be wiped down with ethanol instead of relying on UV lamps, although some labs use the lamps in addition to ethanol wipes to decontaminate work areas. A special metering device is available to measure the output

ECU IAS/CHENEY UNIVERSITY LIBRARY

of UV lamps, and the lamps should be replaced when they fall below the minimum requirements for protection (Westinghouse Electric Company, 1976).

Cultures should be checked routinely for contamination. Indicators in the tissue culture medium change color when contamination is present: for example, medium that contains phenol red changes to yellow because of increased acidity. Cloudiness and turbidity are also observed in contaminated cultures. Once contamination is confirmed with a microscope, infected cultures are generally discarded. Keeping contaminated cultures increases the risk of contaminating other cultures. Sometimes a contaminated cell line can be salvaged by treating it with various combinations of antibiotics and antimycotics in an attempt to eradicate the infection (e.g., see Fitch et al., 1991). However, such treatment may adversely affect cell growth and is often unsuccessful in ridding cultures of contamination.

PREPARING CULTURE MEDIUM

Choice of tissue culture medium comes from experience. An individual laboratory must select the medium that best suits the type of cells being cultured. Chemically defined media are available in liquid or powdered form from a number of suppliers. Sterile, ready-to-use medium has the advantage of being convenient, although it is more costly than other forms. Powdered medium must be reconstituted with tissue culture grade water according to manufacturer's directions. Distilled or deionized water is not of sufficiently high quality for medium preparation; double- or triple-distilled water or commercially available tissue culture water should be used. The medium should be filter-sterilized and transferred to sterile bottles. Prepared medium can generally be stored ≤1 month in a 4°C refrigerator. Laboratories using large volumes of medium may choose to prepare their own medium from standard recipes. This is the most economical approach, but it is time-consuming.

Basic media such as Eagle's minimal essential medium (MEM), Dulbecco's modified Eagle medium (DMEM), Glasgow modified Eagle medium (GMEM), and RPMI 1640 and Ham F10 nutrient mixtures (e.g., Life Technologies) are composed of amino acids, glucose, salts, vitamins, and other nutrients. A basic medium is supplemented by addition of L-glutamine, antibiotics (typically penicillin and streptomycin sulfate), and usually serum to formulate a "complete medium." Where serum is added, the amount is indicated as a percentage of fetal bovine serum (FBS) or other serum. Some media are also supplemented with antimycotics, nonessential amino acids, various growth factors, and/or drugs that provide selective growth conditions. Supplements should be added to medium prior to sterilization or filtration, or added aseptically just before use.

The optimum pH for most mammalian cell cultures is 7.2 to 7.4. Adjust pH of the medium as necessary after all supplements are added. Buffers such as bicarbonate and HEPES are routinely used in tissue culture medium to prevent fluctuations in pH that might adversely affect cell growth. HEPES is especially useful in solutions used for procedures that do not take place in a controlled CO_2 environment.

Most cultured cells will tolerate a wide range of osmotic pressure and an osmolarity between 260 and 320 mOsm/kg is acceptable for most cells. The osmolarity of human plasma is ~290 mOsm/kg, and this is probably the optimum for human cells in culture as well (Freshney, 1993).

Fetal bovine serum (FBS; sometimes known as fetal calf serum, FCS) is the most frequently used serum supplement. Calf serum, horse serum, and human serum are also used; some cell lines are maintained in serum-free medium (Freshney, 1993). Complete

BCU ASC CENTRAL UNIVERSITY LIBRARY

Table A.3C.1 Working Concentrations of Antibiotics and Fungicides for Mammalian Cell Culture

Additive	Final concentration
Penicillin	50–100 U/ml
Streptomycin sulfate	50–100 µg/ml
Kanamycin	100 µg/ml
Gentamycin	50 µg/ml
Mycostatin	20 µg/ml
Amphotericin B	0.25 µg/ml

medium is supplemented with 5% to 30% (v/v) serum, depending on the requirements of the particular cell type being cultured. Serum that has been heat-inactivated (30 min to 1 hr at 56°C) is generally preferred, because heat treatment inactivates complement and is thought to reduce the number of contaminants. Serum is obtained frozen, then is thawed, divided into smaller portions, and refrozen until needed.

There is considerable lot-to-lot variation in FBS. Most suppliers will provide a sample of a specific lot and reserve a supply of that lot while the serum is tested for its suitability. The suitability of a serum lot depends upon the use. Frequently the ability of serum to promote cell growth equivalent to a laboratory standard is used to evaluate a serum lot. Once an acceptable lot is identified, enough of that lot should be purchased to meet the culture needs of the laboratory for an extended period of time.

Commercially prepared media containing L-glutamine are available, but many laboratories choose to obtain medium without L-glutamine, and then add it to a final concentration of 2 mM just before use. L-glutamine is an unstable amino acid that, upon storage, converts to a form cells cannot use. Breakdown of L-glutamine is temperature- and pH-dependent. At 4°C, 80% of the L-glutamine remains after 3 weeks, but at near incubator temperature (35°C) only half remains after 9 days (Barch et al., 1991). To prevent degradation, 100× L-glutamine should be stored frozen in aliquots until needed.

As well as practicing good aseptic technique, most laboratories add antimicrobial agents to medium to further reduce the risk of contamination. A combination of penicillin and streptomycin is the most commonly used antibiotic additive; kanamycin and gentamycin are used alone. Mycostatin and amphotericin B are the most commonly used fungicides (Rooney and Czepulkowski, 1992). Table A.3C.1 lists the final concentrations for the most commonly used antibiotics and antimycotics. Combining antibiotics in tissue culture media can be tricky, as some antibiotics are not compatible, and one may inhibit the action of another. Furthermore, combined antibiotics may be cytotoxic at lower concentrations than is true for the individual antibiotics. In addition, prolonged use of antibiotics may cause cell lines to develop antibiotic resistance. For this reason, some laboratories add antibiotics and/or fungicides to medium when initially establishing a culture but eliminate them from medium used in later subcultures.

All tissue culture medium, whether commercially prepared or prepared within the laboratory, should be tested for sterility prior to use. A small aliquot from each lot of medium is incubated 48 hr at 37°C and monitored for evidence of contamination such as turbidity (infected medium will be cloudy) and color change (if phenol red is the indicator, infected medium will turn yellow). Any contaminated medium should be discarded.

ECU IAS/CENTRAL UNIVERSITY LIBRARY

TRYPSINIZING AND SUBCULTURING CELLS FROM A MONOLAYER

BASIC PROTOCOL

A primary culture is grown to confluency in a 60-mm petri dish or 25-cm^2 tissue culture flask containing 5 ml tissue culture medium. Cells are dispersed by trypsin treatment and then reseeded into secondary cultures. The process of removing cells from the primary culture and transferring them to secondary cultures constitutes a passage or subculture.

Materials

Primary cultures of cells
HBSS *without* Ca^{2+} and Mg^{2+} (see recipe), 37°C
0.25% (w/v) trypsin/0.2% EDTA solution (see recipe), 37°C
Complete medium with serum: e.g., DMEM supplemented with 10% to 15% (v/v) fetal bovine serum (complete DMEM-10; see recipe), 37°C

Sterile Pasteur pipets
37°C warming tray *or* incubator
Tissue culture plasticware or glassware including pipets and 25-cm^2 flasks or 60-mm petri dishes, sterile

NOTE: All incubations are performed in a humidified 37°C, 5% CO_2 incubator unless otherwise specified.

1. Remove all medium from primary culture with a sterile Pasteur pipet. Wash adhering cell monolayer once or twice with a small volume of 37°C HBSS without Ca^{2+} and Mg^{2+} to remove any residual FBS, which may inhibit the action of trypsin.

   Use a buffered salt solution that is Ca^{2+}- and Mg^{2+}-free to wash cells. Ca^{2+} and Mg^{2+} in the salt solution can cause cells to stick together.

   If this is the first medium change, rather than discarding medium that is removed from primary culture, put it into a fresh dish or flask. The medium contains unattached cells that may attach and grow, thereby providing a backup culture.

2. Add enough 37°C trypsin/EDTA solution to culture to cover adhering cell layer.

3. Place plate on a 37°C warming tray 1 to 2 min. Tap bottom of plate on the countertop to dislodge cells. Check culture with an inverted microscope to be sure that cells are rounded up and detached from the surface.

   If cells are not sufficiently detached, return plate to warming tray for an additional minute or two.

4. Add 2 ml of 37°C complete medium. Draw cell suspension into a Pasteur pipet and rinse cell layer two or three times to dissociate cells and to dislodge any remaining adherent cells. As soon as cells are detached, add serum or medium containing serum to inhibit further trypsin activity that might damage cells.

   If cultures are to be split 1/3 or 1/4 rather than 1/2, add sufficient medium such that 1 ml of cell suspension can be transferred into each fresh culture vessel.

5. Add an equal volume of cell suspension to fresh dishes or flasks that have been appropriately labeled.

   Alternatively, cells can be counted using a hemacytometer (see Support Protocol 3) or Coulter counter and diluted to the desired density so a specific number of cells can be added to each culture vessel. A final concentration of ~5×10^4 cells/ml is appropriate for most subcultures.

   For primary cultures and early subcultures, 60-mm petri dishes or 25-cm^2 flasks are generally used; larger petri dishes or flasks (e.g., 150-mm dishes or 75-cm^2 flasks) may be used for later subcultures.

   Cultures should be labeled with patient name, lab number, date of subculture, and passage number.

BCU LIBRARY, UNIVERSITY LIBRARY

6. Add 4 ml fresh medium to each new culture. Incubate in a humidified 37°C, 5% CO_2 incubator.

   If using 75-cm^2 culture flasks, add 9 ml medium per flask.

   Some labs now use incubators with 5% CO_2 and 4% O_2. The low oxygen concentration is thought to simulate the in vivo environment of cells and to enhance cell growth.

7. If necessary, feed subconfluent cultures after 3 or 4 days by removing old medium and adding fresh 37°C medium.

8. Passage secondary culture when it becomes confluent by repeating steps 1 to 7, and continue to passage as necessary.

SUPPORT PROTOCOL 1

FREEZING HUMAN CELLS GROWN IN MONOLAYER CULTURES

It is sometimes desirable to store cell lines for future study. To preserve cells, avoid senescence, reduce the risk of contamination, and minimize effects of genetic drift, cell lines may be frozen for long-term storage. Without the use of a cryoprotective agent freezing would be lethal to the cells in most cases. Generally, a cryoprotective agent such as dimethylsulfoxide (DMSO) is used in conjunction with complete medium for preserving cells at –70°C or lower. DMSO acts to reduce the freezing point and allows a slower cooling rate. Gradual freezing reduces the risk of ice crystal formation and cell damage.

Materials

Log-phase monolayer culture of cells in petri dish
Complete medium
Freezing medium: complete medium (e.g., DMEM or RPMI; see recipes) supplemented with 10% to 20% (v/v) FBS and 5% to 10% (v/v) DMSO, 4°C
Benchtop clinical centrifuge (e.g., Fisher Centrific or Clay Adams Dynac) with 45°C fixed-angle or swinging-bucket rotor

1. Trypsinize log-phase monolayer culture of cells from plate (see Basic Protocol, steps 1 to 4).

   It is best to use cells in log-phase growth for cryopreservation.

2. Transfer cell suspension to a sterile centrifuge tube and add 2 ml complete medium with serum. Centrifuge 5 min at 300 to 350 × *g* (~1500 rpm in Fisher Centrific rotor), room temperature.

   Cells from three or more dishes from the same subculture of the same patient can be combined in one tube.

3. Remove supernatant and add 1 ml of 4°C freezing medium. Resuspend pellet.

4. Add 4 ml of 4°C freezing medium, mix cells thoroughly, and place on wet ice.

5. Count cells using a hemacytometer (see Support Protocol 3). Dilute with more freezing medium as necessary to get a final cell concentration of 10^6 or 10^7 cells/ml.

   To freeze cells from a nearly confluent 25-cm^2 flask, resuspend in roughly 3 ml freezing medium.

6. Pipet 1-ml aliquots of cell suspension into labeled 2-ml cryovials. Tighten caps on vials.

7. Place vials 1 hr to overnight in a –70°C freezer, then transfer to liquid nitrogen storage freezer.

   Alternatively, freeze cells in a freezing chamber in the neck of a Dewar flask according to manufacturer's instructions. Some laboratories place vials directly into the liquid nitrogen

ECU IASTE CENTRAL UNIVERSITY LIBRARY

freezer, omitting the gradual temperature drop. Although this is contrary to the general recommendation to gradually reduce the temperature, laboratories that routinely use a direct-freezing technique report no loss of cell viability on recovery.

Keep accurate records of the identity and location of cells stored in liquid nitrogen freezers. Cells may be stored for many years and proper information is imperative for locating a particular line for future use.

FREEZING CELLS GROWN IN SUSPENSION CULTURE

ALTERNATE PROTOCOL

Freezing cells from suspension culture is similar in principle to freezing cells from monolayer. The major difference is that suspension cultures need not be trypsinized.

1. Transfer cell suspension to a centrifuge tube and centrifuge 10 min at 300 to 350 × *g* (~1500 rpm in Fisher Centrific centrifuge), room temperature.
2. Remove supernatant and resuspend pellet in 4°C freezing medium at a density of 10^6 to 10^7 cells/ml.

   Some laboratories freeze lymphoblastoid lines at the higher cell density because they plan to recover them in a larger volume of medium and because there may be a greater loss of cell viability upon recovery as compared to other types of cells (e.g., fibroblasts).
3. Transfer 1-ml aliquots of cell suspension into labeled cryovials and freeze as for monolayer cultures.

THAWING AND RECOVERING HUMAN CELLS

SUPPORT PROTOCOL 2

When cryopreserved cells are needed for study, they should be thawed rapidly and plated at high density to optimize recovery.

CAUTION: Protective clothing, particularly insulated gloves and goggles, should be worn when removing frozen vials or ampules from the liquid nitrogen freezer. The room containing the liquid nitrogen freezer should be well-ventilated. Care should be taken not to spill liquid nitrogen on the skin.

Materials

Cryopreserved cells stored in liquid nitrogen freezer
70% (v/v) ethanol
Complete medium (e.g., DMEM or RPMI; see recipes) containing 20% FBS (see recipe), 37°C
Tissue culture dish or flask

NOTE: All incubations are performed in a humidified 37°C, 5% CO_2 incubator unless otherwise specified.

1. Remove vial from liquid nitrogen freezer and immediately place it into a 37°C water bath. Agitate vial continuously until medium is thawed.

   The medium usually thaws in <60 sec.

   Cells should be thawed as quickly as possible to prevent formation of ice crystals which can cause cell lysis. Try to avoid getting water around the cap of the vial.
2. Wipe top of vial with 70% ethanol before opening.

   Some labs prefer to submerge the vial in 70% ethanol and air dry before opening.
3. Transfer thawed cell suspension into a sterile centrifuge tube containing 2 ml warm complete medium containing 20% FBS. Centrifuge 10 min at 150 to 200 × *g* (~1000 rpm in Fisher Centrific), room temperature. Discard supernatant.

   Cells are washed with fresh medium to remove residual DMSO.

BCU HSL CENTRAL UNIVERSITY LIBRARY

4. Gently resuspend cell pellet in small amount (~1 ml) of complete medium/20% FBS and transfer to properly labeled culture dish or flask containing the appropriate amount of medium.

   Cultures are reestablished at a higher cell density than that used for original cultures because there is some cell death associated with freezing. Generally, 1 ml cell suspension is reseeded in 5 to 20 ml medium.

5. Check cultures after ~24 hr to ensure that cells have attached to the plate.

6. Change medium after 5 to 7 days or when pH indicator (e.g., phenol red) in medium changes color. Keep cultures in medium with 20% FBS until cell line is reestablished.

   If recovery rate is extremely low, only a subpopulation of the original culture may be growing; be extra careful of this when working with cell lines known to be mosaic.

SUPPORT PROTOCOL 3

DETERMINING CELL NUMBER AND VIABILITY WITH A HEMACYTOMETER AND TRYPAN BLUE STAINING

Determining the number of cells in culture is important in standardization of culture conditions and in performing accurate quantitation experiments. A hemacytometer is a thick glass slide with a central area designed as a counting chamber.

The exact design of the hemacytometer may vary; the one described here is the Improved Neubauer from Baxter Scientific (Fig. A.3C.1). The central portion of the slide is the counting platform, which is bordered by a 1-mm groove. The central platform is divided into two counting chambers by a transverse groove. Each counting chamber consists of a silver footplate on which is etched a 3 × 3–mm grid. This grid is divided into nine secondary squares, each 1 × 1 mm. The four corner squares and the central square are used for determining the cell count. The corner squares are further divided into 16 tertiary squares and the central square into 25 tertiary squares to aid in cell counting.

Accompanying the hemacytometer slide is a thick, even-surfaced coverslip. Ordinary coverslips may have uneven surfaces, which can introduce errors in cell counting; therefore, it is imperative that the coverslip provided with the hemacytometer be used in determining cell number.

Cell suspension is applied to a defined area and counted so cell density can be calculated.

Materials

70% (v/v) ethanol
Cell suspension
0.4% (w/v) trypan blue *or* 0.4% (w/v) nigrosin, prepared in HBSS (see recipe)

Hemacytometer with coverslip (Improved Neubauer, Baxter Scientific)
Hand-held counter

Prepare hemacytometer

1. Clean surface of hemacytometer slide and coverslip with 70% alcohol.

   Coverslip and slide should be clean, dry, and free from lint, fingerprints, and watermarks.

2. Wet edge of coverslip slightly with tap water and press over grooves on hemacytometer. The coverslip should rest evenly over the silver counting area.

Prepare cell suspension

3. For cells grown in monolayer cultures, detach cells from surface of dish using trypsin (see Basic Protocol).

RCU IAS / CENTRAL UNIVERSITY LIBRARY

4. Dilute cells as needed to obtain a uniform suspension. Disperse any clumps.

When using the hemacytometer, a maximum cell count of 20 to 50 cells per 1-mm square is recommended.

Load hemacytometer

5. Use a sterile Pasteur pipet to transfer cell suspension to edge of hemacytometer counting chamber. Hold tip of pipet under the coverslip and dispense one drop of suspension.

Suspension will be drawn under the coverslip by capillary action.

Hemacytometer should be considered nonsterile. If cell suspension is to be used for cultures, do not reuse the pipet and do not return any excess cell suspension in the pipet to the original suspension.

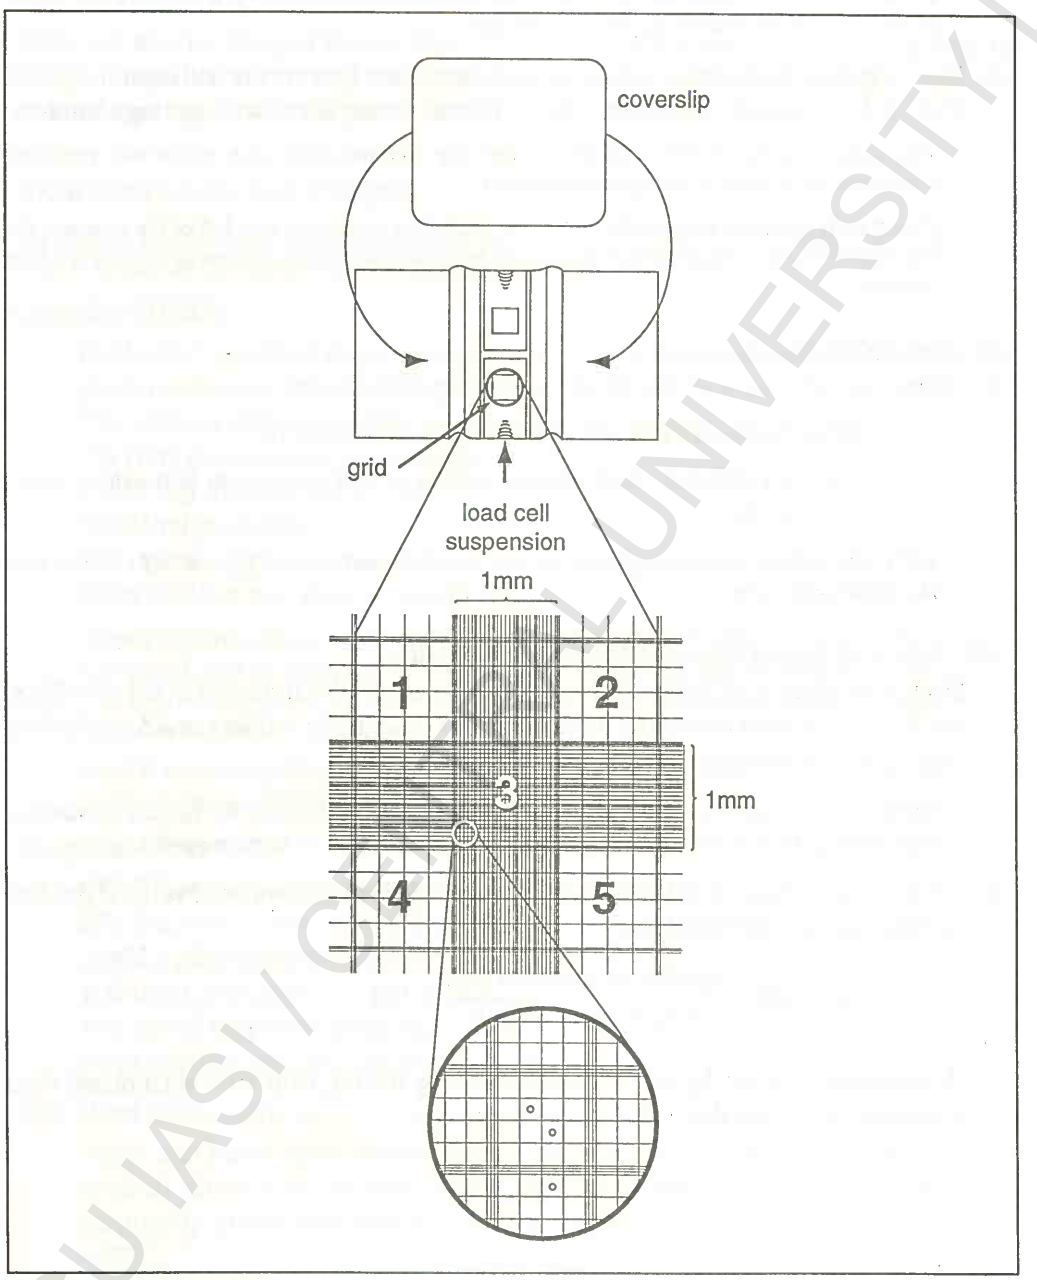

Figure A.3C.1 Hemacytometer slide (Improved Neubauer) and coverslip. Coverslip is applied to slide and cell suspension is added to counting chamber using a Pasteur pipet. Each counting chamber has a 3 × 3–mm grid (enlarged). The four corner squares (1, 2, 4, and 5) and the central square (3) are counted on each side of the hemacytometer (numbers added).

B. C. U. „M. EMINESCU" IAŞI
CHIMIE

BCU IASI / CENTRAL UNIVERSITY LIBRARY

6. Fill second counting chamber.

Count cells

7. Allow cells to settle for a few minutes before beginning to count. Blot off excess liquid.

8. View slide on microscope with 100× magnification.

   A 10× ocular with a 10× objective = 100× magnification.

   Position slide to view the large central area of the grid (section 3 in Fig. A.3C.1); this area is bordered by a set of three parallel lines. The central area of the grid should almost fill the microscope field. Subdivisions within the large central area are also bordered by three parallel lines and each subdivision is divided into sixteen smaller squares by single lines. Cells within this area should be evenly distributed without clumping. If cells are not evenly distributed, wash and reload hemacytometer.

9. Use a hand-held counter to count cells in each of the four corner and central squares (Fig. A.3C.1, squares numbered 1 to 5). Repeat counts for other counting chamber.

   Five squares (four corner and one center) are counted from each of the two counting chambers for a total of ten squares counted.

   Count cells touching the middle line of the triple line on the top and left of the squares. Do not count cells touching the middle line of the triple lines on the bottom or right side of the square.

Calculate cell number

10. Determine cells per milliliter by the following calculations:

    cells/ml = average count per square × dilution factor × 10^4

    total cells = cells/ml × total original volume of cell suspension from which sample was taken.

    10^4 is the volume correction factor for the hemacytometer: each square is 1 × 1 mm and the depth is 0.1 mm.

Stain cells with trypan blue to determine cell viability

11. Determine number of viable cells by adding 0.5 ml of 0.4% trypan blue, 0.3 ml HBSS, and 0.1 ml cell suspension to a small tube. Mix thoroughly and let stand 5 min before loading hemacytometer.

    Either 0.4% trypan blue or 0.4% nigrosin can be used to determine the viable cell number. Nonviable cells will take up the dye, whereas live cells will be impermeable to it.

12. Count total number of cells and total number of viable (unstained) cells. Calculate percent viable cells as follows:

$$\% \text{ viable cells} = \frac{\text{number of unstained cells}}{\text{total number of cells}} \times 100$$

13. Decontaminate coverslip and hemacytometer by rinsing with 70% ethanol and then deionized water. Air dry and store for future use.

EGU IASI / CENTRAL UNIVERSITY LIBRARY

PREPARING CELLS FOR TRANSPORT

Both monolayer and suspension cultures can easily be shipped in 25-cm^2 tissue culture flasks. Cells are grown to near confluency in a monolayer or to desired density in suspension. Medium is removed from monolayer cultures and the flask is filled with fresh medium. Fresh medium is added to suspension cultures to fill the flask. *It is essential that the flasks be completely filled with medium to protect cells from drying if flasks are inverted during transport.* The cap is tightened and taped securely in place. The flask is sealed in a leak-proof plastic bag or other leak-proof container designed to prevent spillage in the event that the flask should become damaged. The primary container is then placed in a secondary insulated container to protect it from extreme temperatures during transport. A biohazard label is affixed to the outside of the package. Generally, cultures are transported by same-day or overnight courier.

Cells can also be shipped frozen. The vial containing frozen cells is removed from the liquid nitrogen freezer and placed immediately on dry ice in an insulated container to prevent thawing during transport.

REAGENTS AND SOLUTIONS

Use Milli-Q-purified water or equivalent for the preparation of cell buffers. For common stock solutions, see ***APPENDIX 2E****; for suppliers, see* ***SUPPLIERS APPENDIX****.*

Complete DMEM

Dulbecco's modified Eagle medium, high-glucose formulation (e.g., Life Technologies), containing:
5%, 10%, or 20% (v/v) FBS, heat-inactivated (optional; see recipe)
1% (v/v) nonessential amino acids
2 mM L-glutamine (see recipe)
100 U/ml penicillin
100 µg/ml streptomycin sulfate
Filter sterilize and store ≤1 month at 4°C

Throughout this manual, the percentage of serum (usually fetal bovine serum, FBS) used in a protocol step is indicated by a numeral hyphenated to the base medium name. Thus, "complete DMEM-10" indicates that 10% FBS is used. Absence of a numeral indicates that no serum is used.

DMEM containing 4500 mg/liter D-glucose can be obtained from Life Technologies. DMEM is also known as Dulbecco's minimum essential medium.

Complete RPMI

RPMI 1640 medium (e.g., Life Technologies) containing:
2%, 5%, 10%, 15%, or 20% FBS, heat-inactivated (optional; see recipe)
2 mM L-glutamine (see recipe)
100 U/ml penicillin
100 µg/ml streptomycin sulfate
Filter sterilize and store ≤1 month at 4°C

FBS (fetal bovine serum)

Thaw purchased fetal bovine serum (shipped on dry ice and kept frozen until needed). Store 3 to 4 weeks at 4°C. If FBS is not to be used within this time, aseptically divide into smaller aliquots and refreeze until used. Store ≤1 year at –20°C.

Repeated thawing and refreezing should be avoided as it may cause denaturation of the serum.

BCU MAIN CENTRAL UNIVERSITY LIBRARY

Inactivated FBS (FBS that has been treated with heat to inactivate complement protein and thus prevent an immunological reaction against cultured cells) is useful for a variety of purposes. It can be purchased commercially or made in the lab. To inactivate FBS, heat serum 30 min to 1 hr in a 56°C water bath.

Alternatively, FBS may be inactivated through radiation treatment.

L-glutamine, 0.2 M (100×)

Thaw commercially prepared frozen L-glutamine or prepare an 0.2 M solution in water, aliquot aseptically into usable portions, then refreeze. For convenience, L-glutamine can be stored in 1-ml aliquots if 100-ml bottles of medium are used and in 5-ml aliquots if 500-ml bottles are used. Store ≤1 year at –20°C.

Many laboratories supplement medium with 2 mM L-glutamine—1% (v/v) of 100× stock—just prior to use.

HBSS (Hanks balanced salt solution)

5.4 mM KCl
0.3 mM Na_2HPO_4
0.4 mM KH_2HPO_4
4.2 mM $NaHCO_3$
1.3 mM $CaCl_2$
0.5 mM $MgCl_2$
0.6 mM $MgSO_4$
137 mM NaCl
5.6 mM D-glucose
0.02% (w/v) phenol red (optional)
Add H_2O to 1 liter and adjust pH to 7.4

HBSS can be purchased from Biofluids or Whittaker.

To prepare HBSS *without* Ca^{2+} and Mg^{2+}, omit the $CaCl_2$, $MgCl_2$, and $MgSO_4$.

Trypsin/EDTA solution

Prepare in sterile HBSS (see recipe) or 0.9% (w/v) NaCl:
0.25% (w/v) trypsin
0.2% (w/v) EDTA
Store ≤1 year (until needed) at –20°C

Specific applications may require different concentrations of trypsin.

Trypsin/EDTA solution is commercially available in various concentrations including 10×, 1×, and 0.25% (w/v). It is received frozen from the manufacturer and can be thawed and aseptically divided into smaller volumes. Preparing trypsin/EDTA from powdered stocks may reduce its cost; however, most laboratories prefer commercially prepared solutions for convenience.

EDTA (disodium ethylenediamine tetraacetic acid) is added as a chelating agent to bind Ca^{2+} and Mg^{2+} ions that can interfere with the action of trypsin.

COMMENTARY

Background Information

At its inception in the early twentieth century, tissue culture was applied to the study of tissue fragments in culture. New growth in culture was limited to cells that migrated out from the initial tissue fragment. Tissue culture techniques evolved rapidly, and since the 1950s culture methods have allowed the growth and study of dispersed cells in culture (Freshney, 1993). Cells dispersed from the original tissue can be grown in monolayers and passaged repeatedly to give rise to a relatively stable cell line.

Four distinct growth stages have been described for primary cells maintained in culture. First, cells adapt to the in vitro environment. Second, cells undergo an exponential growth phase lasting through ~30 passages. Third, the

BCU IASL / CENTRAL UNIVERSITY LIBRARY

growth rate of cells slows, leading to a progressively longer generation time. Finally, after 40 or 50 passages, cells begin to senesce and die (Lee, 1991). It may be desirable to study a particular cell line over several months or years, so monolayer cultures can be preserved to retain the integrity of the cell line. Aliquots of early passage cell suspensions are frozen, then thawed, and cultures reestablished as needed. Freezing monolayer cultures prevents changes due to genetic drift and avoids loss of cultures due to senescence or accidental contamination (Freshney, 1993).

Cell lines are commercially available from a number of sources, including the American Type Culture Collection (ATCC) and the Human Genetic Mutant Cell Repository at the Coriell Cell Repository (CCR). These cell repositories are a valuable resource for researchers who do not have access to suitable patient populations.

Critical Parameters

Use of aseptic technique is essential for successful tissue culture. Cell cultures can be contaminated at any time during handling, so precautions must be taken to minimize the chance of contamination. All supplies and reagents that come into contact with cultures must be sterile and all work surfaces should be kept clean and free from clutter.

Cultures should be 75% to 100% confluent when selected for subculture. Growth in monolayer cultures will be adversely affected if cells are allowed to become overgrown. Passaging cells too early will result in a longer lag time before subcultures are established. Following dissociation of the monolayer by trypsinization, serum or medium containing serum should be added to the cell suspension to stop further action by trypsin that might be harmful to cells.

When subculturing cells, add a sufficient number of cells to give a final concentration of ~5×10^4 cells/ml in each new culture. Cells plated at too low a density may be inhibited or delayed in entry into growth stage. Cells plated at too high a density may reach confluence before the next scheduled subculturing; this could lead to cell loss and/or cessation of proliferation. The growth characteristics for different cell lines vary. A lower cell concentration (10^4 cells/ml) may be used to initiate subcultures of rapidly growing cells, and a higher cell concentration (10^5 cells/ml) may be used to initiate subcultures of more slowly growing cells. Adjusting the initial cell concentration permits establishment of a regular, convenient schedule for subculturing—e.g., once or twice a week (Freshney, 1993).

Cells in culture will undergo changes in growth, morphology, and genetic characteristics over time. Such changes can adversely affect reproducibility of laboratory results. Nontransformed cells will undergo senescence and eventual death if passaged indefinitely. The time of senescence will vary with cell line, but generally at between 40 and 50 population doublings fibroblast cell lines begin to senesce. Cryopreservation of cell lines will protect against these adverse changes and will avoid potential contamination.

Cultures selected for cryopreservation should be in log-phase growth and free from contamination. Cells should be frozen at a concentration of 10^6 to 10^7 cells/ml. Cells should be frozen gradually and thawed rapidly to prevent formation of ice crystals that may cause cells to lyse. Cell lines can be thawed and recovered after long-term storage in liquid nitrogen. The top of the freezing vial should be cleaned with 70% alcohol before opening to prevent introduction of contaminants. To aid in recovery of cultures, thawed cells should be reseeded at a higher concentration than that used for initiating primary cultures. Careful records regarding identity and characteristics of frozen cells as well as their location in the freezer should be maintained to allow for easy retrieval.

For accurate cell counting, the hemacytometer slide should be clean, dry, and free from lint, scratches, fingerprints, and watermarks. The coverslip supplied with the hemacytometer should always be used because it has an even surface and is specially designed for use with the counting chamber. Use of an ordinary coverslip may introduce errors in cell counting. If the cell suspension is too dense or the cells are clumped, inaccurate counts will be obtained. If the cell suspension is not evenly distributed over the counting chamber, the hemacytometer should be washed and reloaded.

Anticipated Results

Confluent cell lines can be successfully subcultured in the vast majority of cases. The yield of cells derived from monolayer culture is directly dependent on the available surface area of the culture vessel (Freshney, 1993). Overly confluent cultures or senescent cells may be difficult to trypsinize, but increasing the time of trypsin exposure will help dissociate resistant cells. Cell lines can be propagated to get

BOSTON UNIVERSITY MEDICAL CENTRAL LIBRARY

sufficient cell populations for cytogenetic, biochemical, and molecular analyses.

It is well accepted that anyone can successfully freeze cultured cells; it is thawing and recovering the cultures that presents the problem. Cultures that are healthy and free from contamination can be frozen and stored indefinitely. Cells stored in liquid nitrogen can be successfully thawed and recovered in over 95% of cases. Several aliquots of each cell line should be stored to increase the chance of recovery. Cells should be frozen gradually, with a temperature drop of ~1°C per minute, but thawed rapidly. Gradual freezing and rapid thawing prevents formation of ice crystals that might cause cell lysis.

Accurate cell counts can be obtained using the hemacytometer if cells are evenly dispersed in suspension and free from clumps. Determining the proportion of viable cells in a population will aid in standardization of experimental conditions.

Time Considerations

Establishment and maintenance of mammalian cell cultures require a regular routine for preparing media and feeding and passaging cells. Cultures should be inspected regularly for signs of contamination and to determine if the culture needs feeding or passaging.

Importing Biological Materials

Scientific cooperation is no longer confined to laboratories at the same institution, nor between laboratories within the boundaries of the United States. More than ever, scientists are forming collaborations with their peers outside the U.S., leading not only to the exchange of knowledge and ideas, but also to the exchange of biological reagents. Thus, investigators need be aware that an import permit may be required to obtain purified proteins, chemically synthesized materials, cell lines, tissues, and other biological materials from abroad. Before requesting any biological material from a laboratory outside the U.S., it is the responsibility of the "receiver" to ascertain whether an import permit is required, to apply for the permit if one is determined to be necessary, and to provide the "shipper" with an official copy of the permit to be included with the shipped material.

There are two government agencies in place to issue permits for the importation of most biologicals. Materials derived from all animals are subject to regulations set forth by the United States Department of Agriculture (USDA) and must be cleared by USDA inspectors at the port of arrival before entry into the United States is authorized. In general, an import permit issued by the USDA is necessary for receipt of any animal-derived material or any biological material (including proteins) that has been in contact with materials of animal origin. The USDA does not have regulatory authority over the importation of human or nonhuman primate material unless it is produced via tissue culture, due to the use of bovine material (fetal bovine serum or calf serum) in tissue culture. The U.S. Public Health Service (UPHS) has jurisdiction over human and nonhuman primate materials. According to UPHS regulations, any etiologic agent, animal host, or vector of human disease may not be imported in the United States nor distributed after importation without being accompanied by a permit issued by the Director of the Centers for Disease Control. Failure to obtain the appropriate import permit will result in the shipment being held at the port of entry until a permit is applied for and issued (a 4- to 6-week process), or it may result in shipment confiscation and destruction by the quarantine officer present.

IMPORTING RESTRICTED BIOLOGICAL MATERIALS

The following is a list of restricted biological materials requiring an import permit: proteins, monoclonal and polyclonal antibodies, antisera, immunoglobins, recombinant products, enzymes, hormones, immunoassay components or kits, animal tissues, blood, cells, cell lines, RNA/DNA extracts, plasmids, vectors, microorganisms—e.g., fungi, bacteria, viruses—and other products that are derived from or have been in contact with animal-derived materials. In addition, materials received from countries shown not to be free of foot-and-mouth disease (see Title 9, code of Federal Regulations, Part 94.1) require an import permit. Note that the USDA will not permit the importation of cell cultures, monoclonal antibodies, ascites fluid, or bovine serum from countries where rinderpest and foot-and-mouth disease are present unless the imported materials are determined to be virus-free. Cell cultures being imported into the U.S. must have been grown only with fetal bovine serum of U.S., Canadian, New Zealand, or Australian origin. Material exposed to bovine products originating in the United Kingdom, Switzerland, Ireland, France, or Portugal may NOT be used, either directly or indirectly, in any animals due to the presence of bovine spongiform encephalopathy (BSE) in those countries, and the material is restricted to in vitro uses only.

CRITERIA FOR HANDLING IMPORTED RESTRICTED MATERIALS

An import permit is only valid for transfer of the material(s) listed on the permit (a permit can cover more than one item), and for shipment between the two laboratories listed on the permit. Therefore, for each laboratory abroad from which biological materials are to be imported, a separate import permit is required. Once biological materials have been received from abroad, the import permit still imposes regulations on how the materials are handled by the receiver. Import permits do not usually authorize direct or indirect exposure of domestic animals—work is limited to in vitro uses only. In addition, permits are only valid for work conducted or directed by the permit holder at his or her facilities. Materials cannot be removed to another location, nor distributed to others, without USDA authorization. There

Copyright © 1997 by John Wiley & Sons, Inc.

BCU MAIN (CENTRAL) UNIVERSITY LIBRARY

is one exception: monoclonal antibodies produced by hybridoma cell lines may be commercially distributed for in vitro uses.

IMPORTING NONRESTRICTED BIOLOGICAL MATERIALS

Any of the restricted materials that do not contain animal- or cell culture-derived products or additives such as albumin, serum, or gelatin, or were not exposed to any infectious agents of agricultural concern, do not need an official import permit. However, an accompanying declaration is required with each shipment to indicate that the material does not contain any animal- or cell culture-derived products or additives. This information should be supplied with each shipment in a clear and concise manner, and be available for the USDA Port of Entry Inspector's review. A separate memo or letter should be included with the shipping documents, such as U.S. Customs declaration and invoice. Note, whether a particular biological material requires an import permit cannot be decided by the investigator; the investigator must contact the USDA for a decision well in advance of making arrangements for importing the material.

PACKAGING BIOLOGICAL MATERIALS FOR IMPORTATION

Imported biological materials are subject to packaging and shipping requirements of various federal and international regulations. Proper packaging is the primary consideration and of utmost importance in the safe transportation of hazardous materials. If the biological material being shipped is infectious or radioactive, this information has to be noted on the outside of the package. In addition, if dry ice is used for shipment, that must be clearly stated on the package. It is of course advantageous to the investigator that the shipped material be packaged in the most efficient way possible, as well as in a form which will ensure its stability. If proteins are to be shipped, it may be better to send the samples lyophilized or blotted on a membrane, rather than in liquid form. This will omit the need for dry ice or ice packs in the packaging, which will save on shipping costs as well as ensure the samples will be stable if receipt of the package meets with unforeseen delays. If sending materials that require dry ice or ice packs, such as antibodies or antisera, there must be enough dry ice to allow the package to maintain the appropriate temperature during shipping for approximately 5 days. This requires utilizing much larger packaging boxes than are normally used to ship the same material within the United States. When shipping cell lines, sometimes it is better to send cells in culture, rather than frozen aliquots. To send cells in culture, the tissue culture flask containing the live cells must be filled to the very top with the appropriate medium, tightly capped, and the seal secured with parafilm. If the tissue culture flask is not completely filled with medium, the resulting air pockets will cause the flasks to explode in flight. Thus, the packaging of any biological material for shipping is an import consideration to ensure success of the scientific collaboration!

OBTAINING AN IMPORT PERMIT APPLICATION

The Division of Veterinary Services of the USDA Animal and Plant Health Inspection Service (APHIS) administers regulatory programs to control the import/export of biological materials. Import permits can be obtained from either local USDA port offices or from APHIS directly: USDA, APHIS, VETERINARY SERVICES, National Center for Import-Export Products Program, 4700 River Road Unit 40, Riverdale, MD 20737-1231, Tel: (301) 734-7830, Fax: (301) 734-8226.

When submitting an import application, (1) obtain the import permit well in advance of the proposed shipping date; (2) inform the supplier of the USDA's requirements, and do not allow shipment of materials until an import permit has been issued and the supplier has received a copy of the permit; (3) list all the potential U.S. ports of entry; (4) specify whether the material is for in vitro or in vivo use and whether it is for commercial distribution or for research in one's own laboratory; (5) list any treatments the material has undergone, such as processing and purification steps involving pH, heat, chromatography, or other methods; and (6) indicate the source(s) of nutrient factors in culture media, cell line designation and history, whether enzymes were used, and what types of viruses (if any) are being studied in the laboratory of origin (all must be listed).

RESOURCES

APHIS Web Site

More information regarding APHIS programs and import/export can be obtained on their internet home page at http://www.aphis.usda.gov.

RCU IAS/CERT LIBRARY

Fax Service of Veterinary Services, National Center for Import-Export

By calling (301) 734-4952, the investigator can access an automated document retrieval system and arrange to have an import application faxed directly, and choose from a menu of documents that describe general instructions for completing the application, as well as information regarding the importation of biological materials from 18 distinct categories.

SELECTED SUPPLIERS OF REAGENTS AND EQUIPMENT

Listed below are addresses and phone numbers of commercial suppliers who have been recommended for particular items used in our manuals because: (1) the particular brand has actually been found to be of superior quality, or (2) the item is difficult to find in the marketplace. Consequently, this compilation may not include some important vendors of biological supplies. For comprehensive listings, see *Linscott's Directory of Immunological and Biological Reagents* (Santa Rosa, CA), *The Biotechnology Directory 1998* (Stockton Press, New York), the annual Buyers' Guide supplement to the journal *Bio/Technology*, as well as various sites on the Internet.

MAIN INDEX

How to Use This Index

A new main index is provided once a year. Thereafter, with the next three supplements, a cumulative supplement index, which amends the main index, will be provided. Thus, readers should consult both the main index and the supplement index when seeking an entry, as page numbers may change for replacement units and new entries will be added.

A

AAA, *see* Amino acid analysis
AAA (*Anguilla anguilla*), as lectin source, 9.1.3 (table)
Absorbance
  in concentration determination
    at A_{205}, 3.1.2, 3.1.4–3.1.6
    at A_{280}, 3.1.1–3.1.2, 3.1.4–3.1.6
    absorption maxima and molar absorptivity of amino acids, 3.1.4–3.1.5
    concentration limits of interfering reagents, 3.1.6 (table)
    conversion equations, 3.1.6
    pH and polarity in, 3.1.5
  of recombinant proteins, 6.1.2, 6.2.8, 7.1.3, 7.1.5, 7.1.6 (table)
  relation to circular dichroism, 7.6.2 (fig.)
  See also Optical density
Absorption, *see* Absorbance, Spectrophotometricmethods, *and* Ultraviolet absorption spectroscopy
Absorption flattening, 7.2.16
Accessibility assays, of recombinant proteins, 7.1.4 (table)
Acetate
  in chromatofocusing, 8.5.3
  production, in *E. coli* fermentation, 5.3.17 (fig.)
Acetic acid, in
  nondenaturing polyacrylamide gels, 10.3.2 (table)
  recombinant protein extraction, 6.1.13
  RP-HPLC, 6.5.9
Acetone, in hydrophobic-interaction chromatography, 8.4.9
Acetone precipitation, in concentration of proteins, 4.5.13–4.5.14, 4.5.29, 12.3.6–12.3.7
Acetonitrile, in RP-HPLC, 6.5.9
Acetylation, in labeling using anhydride, 3.3.2 (fig.), 3.3.11–3.3.12
Acetyl blocking groups, removal of
  by acid hydrolysis, 11.7.9, 11.7.13
  with trifluoroacetic acid, 11.7.10
N-Acetyl-D-galactosamine (GalNAc)
  cleavage of, 12.4.12, 12.4.14
  defined, 12.1.6
β-*N*-Acetyl-D-glucosaminidase, 4.3.15
O-Acetyl-D-galactosamine—linked glycoproteins, monosaccharide distribution and modification in, 12.2.11 (table)
N-Acetyl-D-glucosamine (GlcNAc)
  defined, 12.1.6
  in lectin affinity chromatography, 9.1.7–9.1.8
  monsaccharide distribution and modifications in, 12.2.11 (table)
N-Acetyl-glucosamine-pyrophosphate dolichol (GlcNAc-PP-dolichol), 12.3.8
N-Acetylglucosaminyltransferase (GlcNAc-transferase), 12.3.2 (table), 12.3.3 (fig.), 12.3.8
N-Acetyl-D-neuraminic acid (Neu5Ac), defined, 12.1.7
N-Acetylphenyl ethyl ester, UV absorption spectra, 7.2.1 (fig.)
N-Acetyl-L-tryptophanamide, UV absorption spectra, 7.2.1 (fig.)
N-Acetyl-L-tyrosineamide, UV absorption spectra, 7.2.1 (fig.)
Acid digestion–ninhydrin assay
  applications, 3.4.20
  interfering compounds, 3.4.18 (table)
  method, 3.4.7–3.4.8
  sample size and detection range, 3.4.22 (table)
  TCA precipitation of samples, 3.4.13
Acid hydrolysis
  of phosphoamino acids, 13.1.2, 13.3.1–13.3.2, 13.3.7
  in quantitative amino acid analysis, 3.2.2
  See also Acid digestion–ninhydrin assay
Acid phosphatases
  in phosphorylation detection, 13.5.2–13.5.3, 13.5.6, 13.5.7
  in *S. cerevisiae* expression system, 5.6.2, 5.6.4 (fig.), 5.6.5, 5.6.6
Acid precipitation, of recombinant interleukin1β, 6.2.12
Acids and bases, concentrated, storage, A.2A.3
Acrylamide
  alkylation of cysteine residues using, 15.1.2 (table), 15.1.9
  in nondenaturing electrophoresis
    for acetic acid gels, 10.3.2 (table)
    concentration and molecular weight standard curves, 10.3.5–10.3.7, 10.3.8 (fig.), 10.3.9
    for glycine gels, 10.3.5 (table)

Annexins, 4.3.8–4.3.9, 17.1.26
Anomalous-scattering methods, in X-ray crystallography, 17.3.3
Anomers, defined, 12.1.3
Antibiotics
in baculovirus expression system, 5.5.16–5.5.17
in *S. cerevisiae* expression system, 5.6.3
for tissue culture, A.3C.4 (table)
Antibodies
anti-phosphopeptide, purification
phosphopeptide, 13.6.7–13.6.8
phosphotyrosine, 13.6.8–13.6.9
cross-reactivity of, depleting, 13.6.1, 13.6.2, 13.6.11
in density shift using colloidal gold conjugates, 4.2.40, 4.2.48
in glycophospholipid anchor detection, 12.5.7, 12.5.11, 12.5.12
mammalian expression systems for production of, 5.9.4, 5.9.12–5.9.13
peptides as antigens for, synthesis of, 13.6.6, 13.6.11
in phosphoamino acid detection applications, 13.1.2, 13.4.4
immunoblotting and detection using [^{125}I]protein A, 13.4.1–13.4.2, 13.4.4–13.4.5
in preparation of antibody-Sepharose, 9.5.6–9.5.7
production in rabbits, 13.6.2
purification, 13.6.3–13.6.6
recombinant proteins and
monitoring of folding, 6.1.15
sequence analysis, 6.1.1
sequence analysis, 2.1.14
in solid-phase immunoadsorption, 4.2.5, 4.2.47–4.2.48
synthetic peptides for production of
computer-assisted selection of antigenic sequences, 18.3.2–18.3.4, 18.3.15
coupling peptides to carrier protein, 18.3.8–18.3.9, 18.3.12–18.3.13, 18.3.15–18.3.16
designing multiple antigenic peptide, 18.3.7–18.3.8, 18.3.16
designing peptide for coupling to carrier protein, 18.3.5–18.3.7
free sulfhydryl assay, 18.3.9–18.3.11
manual inspection for sequence selection, 18.3.4, 18.3.5 (table), 18.3.15
reducing cysteine groups, 18.3.11–18.3.12
strategy, 18.3.1–18.3.2
structural features in, 18.3.14–18.3.15
uses of, 13.6.1, 13.6.10–13.6.11
yield of, 13.6.12
Antibody-Sepharose (Ab-Sepharose)
preparation of, 9.5.6–9.5.7
use in
batch purification, 9.5.5
column purification, 9.5.1–9.5.4
Anti-CRD antibody, 12.5.7, 12.5.11, 12.5.12
Antigenic sites, hydropathy profiles in predicting, 2.2.5–2.2.7
Antigens
detection by immunoblotting, UNIT 10.10
formation in murine cells, 5.9.9
isolation of soluble or membrane-bound, by immunoaffinity chromatography, 9.5.1–9.5.4, 9.5.9
Anti-phosphopeptide antibodies, *see* Antibodies, anti-phosphopeptide
Anti-phosphotyrosine antibodies, immunoblotting and detection, 13.4.1–13.4.2, 13.4.4–13.4.5
Antithrombin III (At-III), 5.6.3–5.6.6
α-1-Antitrypsin, 6.4.2
AOX genes, 5.7.3–5.7.11
Apical plasma membranes, 4.2.34, 4.2.48
arg5 genotype, 5.7.3 (table), 5.7.4
Argos hydropathy scale, 2.2.3
Aromatic amino acids
as chromophores in fluorescence, 7.7.1, 7.7.11–7.7.13
in spectrophotometric determination of protein concentration
absorbance, 3.1.1–3.1.2, 3.1.4–3.1.6
fluorescence emission, 3.1.3, 3.1.4–3.1.5
in UV absorption spectroscopy, UNIT 7.2
Aryl ligand, in hydrophobic-interaction chromatography, 8.4.3
Aseptic technique, *see* Sterile technique
aspA transcription terminator, 6.7.1
Asparagine–glycine bonds (Asn-Gly), cleavage with hydroxylamine
on membranes, 11.5.5–11.5.6
in solution, 11.4.4, 11.4.7 (table)
Aspartic acid, cleavage of recombinant proteins at, 7.1.10
Aspartic acid–proline bonds (Asp-Pro), cleavage with formic acid
on membranes, 11.5.5, 11.5.6
in solution, 11.4.4, 11.4.7 (table)
Asp-N endoproteinase, *see* Endoproteinase Asp-N
Assays
comparison of methods, 1.1.3
in fractionation evaluation, 4.1.7–4.1.8
for HIV-1 integrase, 6.5.14
kinetic, UNIT 3.5
laboratory equipment required, 1.1.5
for membrane-bound proteins, 1.2.3
mobility-shift, 9.7.6–9.7.9
protease activity in stock solutions, 11.1.8–11.1.9, 11.1.13
protein purity, structural and functional assessment, 8.1.2–8.1.3
quantitative amino acid analysis in, 3.2.1
ASTRA software, 7.8.6
Asymmetric membrane disks, 4.4.4–4.4.6
Asymmetry, optical, relation to circular dichroism, 7.6.1
Asymmetry factor, in hydrophobic-interaction chromatography, 8.4.9 (fig.), 8.4.10
At-III (human antithrombin III), 5.6.3–5.6.6
ATP
alkaline phosphatase hydrolysis of, 13.5.6–13.5.7
in endosome fusion, 4.3.16
^{32}P-labeled
in direct analysis of kinases, 13.8.10
in permeabilization for phosphorylation studies, 13.8.1–13.8.5, 13.8.8, 13.8.18–13.8.19
specific radioactivity determination, 13.8.11–13.8.15
ATPase, 17.1.43
AtT-20/D16V mouse pituitary cells, 4.2.18–4.2.19
Australian National University Molecular Biology Resources, 2.1.14, 2.1.15 (table)
Autoblending, gradient formation by, 8.2.22
Autoclaving of biohazardous waste, A.2A.2
Autographa californica, *see* Baculovirus expression system
Autoradiography
exposure procedures
direct, 10.11.2–10.11.3
fluorographic, 10.11.3–10.11.4
intensifying-screen, 10.11.4
sensitivity of X-Omat AR film, 10.11.4 (table)
for specific applications, 10.11.3 (table)
TranScreen intensifying screen, 10.11.4–10.11.5
film
handling of, 10.11.2
preflashing of, 10.11.5
types of, 10.11.1–10.11.2

of phosphoamino acids, 13.3.5, 13.3.8, 13.8.19
processing
automated, 10.11.5
manual, 10.11.5–10.11.6
quantitative, 10.11.2
two-dimensional gel electrophoresis, 10.4.26, 10.4.30
Avidin, 3.6.10, 3.6.11, 3.6.12
Avidin-biotin, immunoprobing with, 10.10.3–10.10.4
Azide
detection, A.2A.22–A.2A.23
disposal, A.2A.21–A.2A.22

merits and limitations, 4.2.2
method, 4.2.1 (fig.), 4.2.12–4.2.14
requirements, 4.2.49
Centrifuges
analytical vs. preparative, 7.5.5
concentration and desalting with, 4.4.8–4.4.9
relative centrifugal force and speed equation, A.2C.1
maximum rotating radii, A.2C.4–A.2C.5 (table)
nomograms for conversion, A.2C.2–A.2C.3 (fig.)
Ceramide, 12.5.12
Cetyltrimethylammonium bromide, in inclusion body extraction, 6.3.8
cGMP-PrK, *see* Cyclic nucleotide–dependent protein kinases *and* Kinases
Chaotropic agents
in chemical cleavage, 11.4.2, 11.4.3, 11.4.4
in enzymatic digestion of proteins in solution, 11.1.2 (table), 11.1.4–11.1.5
Chaperones
crystallizable domains, 17.3.12
in folding, 1.3.2–1.3.3, 5.9.9, 6.1.15, 6.4.2, 6.4.6
in fusion expression systems, 6.7.10–6.7.11
Chaperonins, 17.1.41–17.1.42
CHAPS (3-[(3-cholamidopropyl)-dimethylammonio]-1-propane sulfonate), in
enzymatic digestion of proteins in solution, 11.1.1–11.1.3
folding and purification of recombinant proteins, 6.5.14, 6.5.21
glycoprotein denaturation, 12.4.14
see (3[(3-cholamidopropyl)-dimethylammonio]-1-propane- sulfonate)
Characterization of proteins
electroblotting of polyacrylamide gels for, 10.7.1
molecular weight determination by electrophoresis,UNITS 10.1 & 10.3
properties in, 1.1.4–1.1.5
of recombinant proteins
chemical identity, 7.1.2–7.1.3
contaminants, 7.1.1–7.1.2
N-terminal heterogeneity in *E. coli*, 7.1.9–7.1.11
physical and conformational, 7.1.3–7.1.9
strategy, 7.1.9
by UV absorption spectroscopy, UNIT 7.2

PROTEIN CENTER LIBRARY

in subcellular fractions, 4.3.13–4.3.16, 4.3.18–4.3.19
Charge-coupled devices (CCDs), 10.12.5
Charge heterogeneity, determining, in recombinant proteins, 7.3.13 (fig.), 7.3.13–7.3.15, 7.3.18–7.3.21, 7.3.22 (fig.), 7.3.23 (figs.)
Charge-injection devices (CIDs), 10.12.5
Charge of proteins
in aggregation, 6.4.6
capillary electrophoresis based on, 10.9.6–10.9.8
in nondenaturing electrophoresis, 10.3.10
pH and isoelectric point in, 8.2.1
purification methods based on, 1.1.4
Charge-to-shape ratio, 10.9.12
Chelating agents, in dye affinity chromatography, 9.2.15
Chelating groups, in MCAC, 9.4.13
Chemical analysis
chemical cleavage
of GPI-anchored proteins, 12.5.7, 12.5.12
on membranes, UNIT 11.5
in solution, UNIT 11.4
digestion in gels for sequence analysis, UNIT 11.3
enzymatic digestion
in solution, UNIT 11.1
on membranes, UNIT 11.2
reversed-phase isolation of peptides, UNIT 11.6
Chemical cleavage
of fusion proteins, 5.1.5–5.1.6
in gels, CNBr in, 11.3.9–11.3.10
of GPI-anchored proteins, 12.5.7, 12.5.12
on membranes
analysis and separation of fragments, 11.5.6–11.5.7
at Asn-Gly bonds with hydroxylamine, 11.5.5–11.5.6
at Asp-Pro bonds with formic acid, 11.5.5
with CNBr of Edman degraded proteins, 11.5.3
at C-terminus of Met residues with CNBr, 11.5.1–11.5.2
at C-terminus of Trp residues with BNPS-skatole, 11.5.4–11.5.5
cysteine reduction and alkylation, 11.5.8
sample size, 11.5.8
in solution
at Asn-Gly bonds with hydroxylamine, 11.4.4–11.4.5, 11.4.7 (table)
at Asp-Pro bonds with formic acid, 11.4.4, 11.4.7 (table)
at C-terminus of Met residues with CNBr, 11.4.1–11.4.2, 11.4.5–11.4.8
at C-terminus of Trp residues with BNPS-skatole, 11.4.2–11.4.3, 11.4.5–11.4.8
Chemical reactivity, of recombinant proteins, 7.1.4 (table)
Chemicals, hazardous
use and disposal, A.2A.2–A.2A.26
See also individual chemicals
Chemiselective adsorption, defined, 9.3.10
Chinese hamster ovary (CHO) cells
carboxylation of factor VIII in, 5.9.10
cell cycle and protein production, 5.9.12
culture of, 5.9.11
DG44 cells, 5.9.5, 5.9.11
DXB11 cells, 5.9.5, 5.9.11
glycosylation in, 5.9.10
K1 cells, 5.9.5
pro3$^-$ cells, 5.9.5
promoters for, 5.9.4–5.9.5
for recombinant protein production, 5.9.3 (table), 5.9.4–5.9.5, 5.9.6, UNIT 5.10
selectable markers for, 5.9.6
transfection of glycosylation genes into, 5.9.12
Chirality, relation to circular dichroism, 7.6.1
Chloramine T, iodination using, 3.3.5–3.3.6
N-Chloro-4-methylbenzenesulfonamide, 3.3.3
4-Chloro-1-naphthol (4CN), in immunoblot visualization, 10.10.5 (table)
Chlorotrimethylsilane, disposal of, A.2A.11
3-[(3-Cholamido propyl)-dimethylammonio]-1-propane sulfonate, *see* CHAPS
CHO cells, *see* Chinese hamster ovary cells
3[(3-Cholamidopropyl)-dimethylammonio]-1-propane-sulfonate,
in IEF, 10.4.31–10.4-32
in lysis for immunoprecipitation, 13.2.1–13.2.4, 13.2.7
Cholesterol, in density shift using digitonin, 4.2.35–4.2.37, 4.2.48
Chou and Fasman method of secondary structure prediction
accuracy of, 2.3.2
amino acid positional preferences in αhelices, 2.3.5
applying, 2.3.4 (fig.), 2.3.8, 2.3.9 (fig.), 2.3.10 (fig.)
compared with other methods, 2.3.11–2.3.18
conformational preference parameters, 2.3.3–2.3.5
for peptide sequences in antibody production, 18.3.2–18.3.4, 18.3.15
rules, 2.3.11 (table)
Chromatofocusing
applications, 8.5.1, 8.5.8
medium and buffer selection and preparation, 8.5.1, 8.5.3, 8.5.4 (table), 8.5.5 (table)
polybuffer removal from protein, 8.5.8
regeneration of column, 8.5.7
separation of proteins by, 8.5.3, 8.5.5–8.5.7
strategic planning, 8.5.1–8.5.3
troubleshooting guide, 8.5.9 (table)
Chromatographic titration curves, in ion-exchange chromatography, 8.2.25, 8.2.26 (fig.), 8.2.28
Chromatography
adsorptive vs. nonadsorptive, 8.4.1
affinity, *see* Affinity chromatography
of chemically cleaved fragments, 11.4.8, 11.5.6
chromatofocusing, UNIT 8.5
gel filtration, UNIT 8.3
hydrophobic-interaction, UNIT 8.4
hydroxylapatite, UNIT 8.6
immunoaffinity
batch method, 9.5.5
column method, 9.5.1–9.5.4, 9.5.9
preparation of antibody-Sepharose for, 9.5.6–9.5.7, 9.5.9
in iodination product separation, 3.3.8–3.3.9, 3.3.17
ion-exchange, UNIT 8.2
of nonrecombinant soluble proteins, 1.3.5
properties of proteins as basis for, 1.1.4
of radiolabeled glycoconjugates, 12.2.14
of recombinant proteins
buffer compatibility, 6.1.16–6.1.17
equipment, 6.1.18–6.1.19
resolution
capacity in, 8.1.6–8.1.7
determination and parameters affecting, 8.1.5–8.1.7
efficiency in, 8.1.7–8.1.8, 8.1.9 (fig.)
selectivity in, 8.1.7, 8.1.8, 8.1.9 (fig.), 8.3.27
RP-HPLC, UNIT 11.6
strategies
assessing protein purity, 8.1.2–8.1.3
bead size in resolution, 8.1.4
capture stage, 8.1.3–8.1.4
intermediate purification, 8.1.4
optimizing purification, 8.1.4–8.1.5
polishing stage, 8.1.4
yield and purity of target protein, 8.1.1–8.1.3
thin-layer, *see* Thin-layer chromatography
for X-ray crystallography samples, 17.3.8

Chromogenic substrates, immunoblot visualization with, 10.10.5 (table), 10.10.5–10.10.6, 10.10.9–10.10.12
Chymotrypsin
conditions for activity, 11.1.2 (table)
proteolysis of undenatured substrates, 11.1.6 (table)
sequence analysis of, 11.1.17 (table)
specificity, 11.1.14–11.1.15
specificity of digestion, 11.1.12 (table)
Chymotrypsinogen, 8.3.20 (fig.)
cI857 gene, 5.2.2, 5.2.14
Circular dichroism (CD)
and absorbance, 7.6.2 (fig.)
aromatic amino acids, contribution of, 7.6.1, 7.6.5 (fig.), 7.6.15–7.6.18, 7.6.19–7.6.21
buffers for determining, 7.6.9–7.6.10
disulfide bonds, contribution of, 7.6.1, 7.6.18
and ellipticity, 7.6.3–7.6.4
and fluorescence, 7.6.21
histidine, contribution of, 7.6.1
mutations, analysis by, 7.6.20 (fig.), 7.6.21
phenylalanine, contribution of, 7.6.1, 7.6.16
in recombinant protein characterization, 7.1.6 (table), 7.1.7–7.1.8
requirements for, molecular, 7.6.1
spectra
artifacts in, 7.6.22 (fig.)
for cathepsin D, 7.6.17 (fig.)
for GM-CSF, 7.6.6 (fig.)
for hen egg white lysozyme, 7.6.8 (fig.)
for proteins with high helix concentration, 7.6.7 (fig.)
for CSA, 7.6.8 (fig.)
interpretation of, 7.6.15–7.6.19, 7.6.21–7.6.22
parameters for scanning, 7.6.11 (table), 7.6.13 (fig.)
recording, 7.6.10–7.6.15
spectrometer
calibration of, 7.6.8
characteristics of, 7.6.7
cells for, 7.6.8–7.6.9
units for, 7.6.3
cI repressor gene, 5.1.2
cI repressor protein, in thioredoxin expression system, 6.7.2–6.7.3
cis Golgi stack, in mammalian cells, 5.9.10
cis-trans isomerization, 6.4.1, 6.4.6
CL100, 13.1.3
^{14}C labeling
applications, 3.3.16–3.3.17
at cysteine residues using iodoacetic acid oriodoacetamide, 3.3.13
at lysine or N-terminus by acetylation using anhydride, 3.3.11–3.3.12
at lysine or N-terminus by reductive alkylation, 3.3.12
in N-linked glycosylation, 12.3.5
during peptide synthesis, 3.3.14–3.3.15
strategies, 3.3.1 (table)

Clarification of protein samples, 4.5.2, 4.5.3 (fig.)
Classification of proteins, by
function, 1.2.1, 1.2.2 (table)
size, 1.2.1
structural characteristics, 1.2.1
Clathrin-coated vesicles
density shift using gold conjugates, 4.2.48
purification, 4.2.47
Cleavage, *see* Chemical cleavage *and* Enzymatic digestion
Cloning
single-cell, 5.10.9–5.10.10

Colicins, 17.1.40
Collagenase, in fusion protein cleavage, 5.1.6
Colloidal gold conjugates, in density shift centrifugation
applications, 4.2.48–4.2.49
merits and limitations, 4.2.6–4.2.7
method, 4.2.37–4.2.42
requirements, 4.2.51
Colorimetric methods
for pyroglutamate aminopeptidase activity, 11.7.4–11.7.5
for quantitation of free sulfhydryls, 15.1.13
total protein assays, UNIT 3.4
Colorimetric microkjeldahl nitrogen, calibration plots, 3.4.17 (table)
Column packing, ion-exchange gel, 8.2.20
Columns, in
capillary electrophoresis, 10.9.1, 10.9.2
chromatofocusing
packing, 8.5.5–8.5.6
regenerating, 8.5.7
gel-filtration chromatography
for inclusion body extraction, 6.3.11
of recombinant proteins, 6.2.9, 6.2.13, 6.3.4–6.3.5, 6.5.5
hydroxylapatite chromatography, 8.6.1
immunoaffinity chromatography, 9.5.1–9.5.4, 9.5.2 (fig.)
required in laboratory, 1.1.5
Compact domains, 2.3.1
Comparative homology modeling, 2.3.3
COMPARE (software), 2.1.3
Computational methods for protein sequence analysis, UNIT 2.1
Computer-assisted selection of antigenic peptide sequences, 18.3.2–18.3.4, 18.3.15
Computer software, *see* Software
Concanavalin A (Con A)
in glycoprotein purification, 9.1.2 (table)
-Sepharose affinity chromatography, 9.1.4–9.1.6
Concentration determination
at A_{205}, 3.1.2, 3.1.4–3.1.6
at A_{280}, 3.1.1–3.1.2, 3.1.4–3.1.6
fluorescence emission, 3.1.3, 3.1.4–3.1.5
Concentration methods
acetone precipitation, 12.3.6–12.3.7
dialysis through regenerated cellulose tubing, 4.4.1–4.4.4
for protein samples, 4.5.2–4.5.3
for recombinant proteins
equipment, 6.1.19
HIV-1 integrase, 6.5.12
interleukin 1β, 6.2.8, 6.2.9
precipitation, 5.2.12, 5.2.15
for soluble proteins, 1.3.4–1.3.5
ultrafiltration
with centrifugal ultrafilters, 4.4.8–4.4.9
membrane selection and characteristics, 4.4.9–4.4.12
tangential-flow, 4.4.6–4.4.8
through asymmetric membrane disks, 4.4.4–4.4.6
Concentration polarization, 4.4.11
Conductivity measurements, 4.4.3
Conformational changes and switches, analysis by electronmicroscopy, 17.2.10–17.2.11
Conformation of recombinant proteins, 7.1.3–7.1.8
Conformers, defined, 12.1.4–12.1.5
Consensus sequence, 2.1.10
Constitutive route in translocation, 5.9.7–5.9.9
Contact blots, protein detection in polyacrylamide gels, 10.6.2–10.6.3, 10.6.6–10.6.8
Contaminants
in assessment of protein purity, 8.1.2
in hydrophobic-interaction chromatography, 8.4.13–8.5.14
in ion-exchange media, 8.2.24
protein, 11.10.7–11.10.8
in recombinant expression systems, 6.1.17
Continuation in sequence analysis, 2.1.1
Continuous electrophoresis
nondenaturing, 10.3.1–10.3.5, 10.3.9–10.3.10
SDS-PAGE, 10.1.13–10.1.14, 10.1.33
Continuous gradients
in differential centrifugation by equilibrium, 4.2.9–4.2.10
in gradient fractionation using nonionic iodinated solutes, 4.2.21
in rate zonal centrifugation using sucrose, 4.2.13
Coomassie blue
brilliant blue-G, contaminants in, 11.2.6
in digital electrophoresis analysis, 10.12.5, 10.12.10
dye–binding assay
applications and reliability, 3.4.10, 3.4.20–3.4.21
interfering compounds, 3.4.18 (table)
method, 3.4.10–3.4.11
sample size and detection range, 3.4.22 (table)
in gel electrophoresis
blot transfer membrane staining, 10.8.2, 10.8.6–10.8.7
continuous nondenaturing, 10.3.3
denaturing discontinuous, 10.1.7
SDS-PAGE, 10.1.32
sensitivity and membrane compatibilities, 10.8.1 (table)
protein detection in polyacrylamide gels
acid-based Coomassie brilliant blue G-250, 10.5.3, 10.5.11
Coomassie brilliant blue R-250, 10.5.1–10.5.2, 10.5.11
rapid Coomassie brilliant blue R-250 staining, 10.5.2–10.5.3, 10.5.11
recipes, 10.5.9, 10.5.10
two-dimensional gel electrophoresis, 10.4.30, 10.4.36
Copper ion–dependent assays for total protein, 3.4.17–3.4.18
Copper ions, 5.6.2, 9.4.12–9.4.13
Copy number, 5.6.2, 5.8.14
Corey-Pauling α-helical geometry, 2.3.1
Cosolvents, in folding of recombinant proteins, 6.4.4, 6.4.5, 6.4.6, 6.5.3
Cotransfection, of selectable markers, 5.9.6
Cotranslational folding, 14.1.1
Coupling methods, for synthetic peptides
using a carbodiimide, 18.3.13
comparison of methods, 18.3.1, 18.3.15–18.3.16
design of peptide and, 18.3.5–18.3.7
using heterobifunctional reagent, 18.3.8–18.3.9
using homobifunctional reagent, 18.3.12
photochemical, 18.3.13
Covalent modification, of recombinant proteins expressed by mammalian cells, 5.9.10
CRD (cross-reacting determinant), 12.5.7, 12.5.11, 12.5.12
Cresol compounds, Folin assay for, 3.4.16
Cross-linked proteins, purification
detergents in, 1.3.5
strategies, 1.2.3
Cross-linking reagents, for coupling synthetic peptides to carrier proteins, 18.3.1, 18.3.8–18.3.9, 18.3.12–18.3.13, 18.3.15–18.3.16
Cross-reacting determinant (CRD), 12.5.7, 12.5.11, 12.5.12
Crowding agents, in protein precipitation, 4.5.15–4.5.16, 4.5.30–4.5.32
Cryo–electron microscopy, 17.2.17 (fig.), 17.2.18–17.2.19
Cryopreservation, *see* Freezing of cells
Crystallization, in protein characterization, 1.1.5, 6.1.16, 6.1.18
Crystallography, *see* X-ray crystallography
Crystals, two-dimensional, visualization by electronmicroscopy, 17.2.15, 17.2.19–17.2.20

EMBL Profile Neural Network (PHD) method of secondary structure prediction
accuracy, 2.3.2–2.3.3
applying, 2.3.8
basis of, 2.3.7
compared with other methods, 2.3.11–2.3.18
Internet location, 2.3.18 (table)
Emphaze, 9.3.9
Enantiomers, 12.1.3, 12.1.6
Endocrine granules, fractionation, 4.1.8 (table)
Endocrine tissues, gradient fractionation using deuteriumoxide, 4.2.18–4.2.19
Endocytosis, in density shift using gold conjugates, 4.2.6–4.2.7, 4.2.48
Endoglycosidases
in glycoprotein cleavage
comparison of, 12.4.5 (fig.)
endoglycosidase D, 12.4.14
endoglycosidase F_2, 12.4.3–12.4.4, 12.4.13–12.4.14, 12.4.15
endoglycosidase H, 12.4.2–12.4.3, 12.4.12–12.4.13, 12.4.15
estimating N-linked oligosaccharide chains, 12.4.6–12.4.7
gel filtration of released N-linked oligosaccharide chains, 12.4.8–12.4.12, 12.4.15
purchasing or purifying enzyme, 12.4.14
specificities, 12.4.1
strategy, 12.4.1
sugar chains in, 12.4.4 (fig.)
in oligosaccharide cleavage, 12.3.5–12.3.6, 12.3.8
Endoplasmic reticulum
density gradient electrophoresis, 4.2.30
density shift using digitonin, 4.2.36, 4.2.38 (fig.), 4.2.48
endoglycosidase H sensitivity, 12.4.12–12.4.13
fractionation, 4.1.8 (table)
gel filtration, 4.2.47
glycosylation in, 5.6.5
in protein synthesis, 5.9.7–5.9.10
in rat pancreas, 4.2.15 (fig.)
Endoproteases, *see* Proteases
Endoproteinase Asp-N
conditions for activity, 11.1.2 (table)
proteolysis of undenatured substrates, 11.1.6 (table)
specificity of digestion, 11.1.12 (table)
Endoproteinase Glu-C
conditions for activity, 11.1.2 (table)
in digestion on PVDF membranes, 11.2.2 (table), 11.2.4–11.2.5
proteolysis of undenatured substrates, 11.1.6 (table)
sequence analysis of, 11.1.17 (table)
specificity of digestion, 11.1.12 (table)
Endoproteinase Lys-C
buffer compatibilities, 11.1.13–11.1.16
compatibility with other proteases, 11.1.13–11.1.16
conditions for activity, 11.1.2 (table)
in digestion on PVDF membranes, 11.2.2 (table), 11.2.4–11.2.5
proteolysis of undenatured substrates, 11.1.6 (table)
sequence analysis of, 11.1.17 (table)
specificity of digestion, 11.1.12 (table)
Endosomal carrier vesicles (ECV), 4.3.2 (table), 4.3.4, 4.3.14, 4.3.15–4.3.16, 4.3.18
Endosomes
composition and morphology, 4.3.18–4.3.19
density shift using colloidal gold conjugates, 4.2.40
electrophoresis, 4.2.27–4.2.29, 4.2.30 (fig.), 4.2.47
fractionation, 4.1.8 (table), UNIT 4.3
fusion events in in vitro fusion assay, 4.3.8, 4.3.15–4.3.16
labeling conditions for characterization, 4.3.2 (table)
latency, 4.3.7
Endotoxins
detection and elimination, 7.1.2
in recombinant protein contamination, 6.1.17
End-point assay, in baculovirus expression system, 5.5.8–5.5.9
Engineering, *see* Protein engineering
Enhanced chemiluminescence, in anti-phosphotyrosine antibody detection, 13.4.3–13.4.5
Enterokinase
in fusion protein cleavage, 5.1.6
in thioredoxin fusion protein cleavage, 6.7.1, 6.7.2 (fig.), 6.7.4
Enthalpy, protein thermostability, 7.9.10–7.9.13
Enzymatic cleavage, in N-terminal methionine removal, 6.1.3
Enzymatic digestion
capillary electrophoresis in monitoring, 10.9.1, 10.9.11–10.9.13
in gels
amino acid analysis of SDS-PAGE proteins, 11.3.6–11.3.7
CNBr in, 11.3.9–11.3.10
concentration of protein in, 11.3.1 (table), 11.3.8–11.3.9
database searching in sequencing, 11.3.12
density of protein in, 11.3.9
glycosylation in resistance to, 11.3.9
laser desorption mass spectra in sequencing, 11.3.11
reduction and alkylation of SDS-PAGE proteins, 11.3.7
with SDS, 11.3.4–11.3.5, 11.3.8
of transferrin, 11.3.9, 11.3.11 (fig.)
trypsin and lysyl endopeptidase in, 11.3.7–11.3.8
with Tween 20, 11.3.1–11.3.4, 11.3.8
without detergent, 11.3.5–11.3.6
of GPI-containing proteins, 12.5.5–12.5.7, 12.5.11–12.5.12
of histidine tags, 6.5.13, 6.5.21, 6.5.22–6.5.23
in MCAC, 9.4.14
of oligosaccharides, endoglycosidase and glycoamidaserelease, 12.3.5–12.3.6, UNIT 12.4
in phosphorylation detection
with acid phosphatase, 13.5.2–13.5.3
with alkaline phosphatase, 13.5.3
applications, 13.5.1
^{32}P measurement and identification, 13.5.5, 13.5.6
with protein serine/threonine phosphatases, 13.5.3–13.5.4
with protein tyrosine phosphatases, 13.5.4
strategy, 13.5.1–13.5.2, 13.5.5–13.5.7
on PVDF membranes, UNIT 11.2
in solution
endoprotease activity, conditions for, 11.1.2 (table)

BOSTON UNIVERSITY / CENTER FOR SCIENCE LIBRARY

limited and partial digestion, 11.1.16
under nondenaturing conditions, 11.1.1, 11.1.3
peptide mapping, 11.1.11
protease compatibilities, 11.1.13–11.1.16
protease-resistant proteins, 11.1.6 (table), 11.1.11, 11.1.13 11.1.15 (fig.), 11.1.16
protease specificities, 11.1.11
protease stock preparation, 11.1.7–11.1.9, 11.1.13
reduction and alkylation of peptides in digest mixtures, 11.1.10
SDS in, 11.1.5–11.1.7, 11.1.15–11.1.16
urea or guanidine·HCL in, 11.1.4–11.1.5 11.1.13–11.1.16
Enzyme assay, in baculovirus expression systems, nutrientlevel monitoring, 5.5.12–5.5.13
Enzymes
calibration plots for biuret assay, 3.4.2 (table)
characterization, properties in, 1.1.5
as contaminant in ion-exchange chromatography, 8.2.24
in folding of proteins, 6.4.1–6.4.2, 6.4.4
functional assessment, 8.1.2
in fusion protein cleavage, 5.1.5–5.1.6
iodination using, 3.3.6–3.3.7
kinetics, assays of UNIT 3.5
as markers
in density gradient electrophoresis, 4.2.30 (fig.)
in density shift using digitonin, 4.2.36, 4.2.38 (fig.)
in density shift using gold conjugates, 4.2.48
in gradient fractionation using nonionic iodinated solutes, 4.2.22
for lectin adsorption, 4.2.34, 4.2.35
in subcellular fractionation, 4.3.1–4.3.3, 4.3.14, 4.3.18
in zonal centrifugation, 4.2.15 (fig.)
oligosaccharide and, glycosylation inhibition, 12.3.2 (table) 12.3.3 (fig.), 12.3.8
in phosphorylation
digestion of phosphoproteins, UNIT 13.5
kinases, 13.1.3
labeling studies of, 13.1.1–13.1.2
phosphatases, 13.1.3–13.1.4
post-translational modifications in insect cells, 5.4.3
proteases, in SDS-PAGE, 10.1.7, 10.1.32–10.1.33
purification, for industry vs. research, 1.1.1
purification strategies, of intracellular, 1.2.2
purification table, 8.1.3 (table)
recombinant
folding and purification, 6.5.10–6.5.14, 6.5.21–6.5.25
gel filtration in guanidine hydrochloride, 6.3.12–6.3.15
in recombinant expression systems
inclusion body formation, 6.1.3
in viscosity and proteolysis, 6.1.7, 6.1.10
in recombinant protein extraction, 6.5.3
recombinant proteins and, in folding, 6.1.15

in *E. coli* expression systems, 5.3.7, 5.3.16
Hash functions, 2.1.8
Haworth representation of monosaccharides, 12.1.4, 12.1.5
4HCCA (α-cyano-4-hydroxycinnamic acid), in mass spectrometry, 16.1.6, 16.2.3 (fig.)
Heat sealing glass tubes, 3.4.8–3.4.9
Heat-shock proteins
crystallizable domains, 17.3.12
in *E. coli* expression systems, 5.2.1, 5.2.16
in folding of proteins, 5.9.8 (fig.), 5.9.9
Heat treatment, for fusion protein purification, 6.7.8–6.7.9
Heavy metals, 4.4.10, 6.4.5
Heavy metal clusters, for labeling in electron microscopy, 17.2.21, 17.2.22 (fig.), 17.2.24
HeLa cells, for recombinant protein expression, 5.9.3 (table), 5.9.4
Helical net method of secondary structure prediction, 2.3.2
Helical wheel method of secondary structure prediction
applications, 2.3.1–2.3.2
basis of, 2.3.7–2.3.8
Helices
amino acid positional preferences in, 2.3.5
characteristics, 2.3.11 (table)
Chou and Fasman prediction rules, 2.3.11 (table)
conformational preference parameters, 2.3.3–2.3.5
in hemoglobin, IL-1β, and profilin, 2.3.4 (fig.) 2.3.12–2.3.14, 2.3.18 (fig.)
Helix-loop-helix motifs, 17.1.18
Helix-turn-helix motifs, 17.1.13, 17.1.16
Hemacytometer, A.3C.8–A.3C.10, A.3C.13
Hemiacetal, defined, 12.1.3
Hemiketals, defined, 12.1.3, 12.1.4 (fig.)
Hemoglobin
desalting, 8.3.13 (fig.)
hydropathy profile, 2.2.7, 2.2.8 (fig.)
secondary structure prediction
Chou and Fasman method, 2.3.4 (fig.)
comparison of methods, 2.3.11–2.3.18
Henderson-Hasselbach relationship, 6.1.2
Hen egg white lysozyme, hydropathy profiles, 2.2.2 (fig.)
Heparin-agarose chromatography, 9.6.15
Hepatitis B surface antigen, formation in murine cells, 5.9.9
HEPES, in permeabilization, 13.8.3
Heterobifunctional reagent, for coupling synthetic peptides to carrier proteins, 18.3.5–18.3.6, 18.3.8–18.3.9, 18.3.15–18.3.16
Heterologous protein expression, UNIT 5.7
Heteropolyanions, in protein precipitation, 4.5.20
Hewlett-Packard G1009 A C-terminal sequencing system
chemistry used by, 11.8.2, 11.8.5 (fig.), 11.8.5–11.8.6
HPLC in, 11.8.2, 11.8.6
results produced by, 11.8.9–11.8.12 (figs.)
sample preparation for, 11.8.1
use in automated C-terminal sequencing, 11.8.1–11.8.2, 11.8.4–11.8.13
Hewlett-Packard G1005A N-terminal sequencing system
using liquid samples, 11.10.17–11.10.19, 11.10.37
optimizing PTH amino acid separation, 11.10.21
sample cartridge, 11.10.3–11.10.4
using sequencing PVDF-bound samples, 11.10.19–11.10.21
Hexosamines, 12.2.24
Hexoses, 12.2.24
HIC, *see* Hydrophobic-interaction chromatography
High-cell density methods of *E. coli* production, 5.3.8–5.3.9, 5.3.14–5.3.16, 5.3.17 (fig.)
High-mobility group (HMG) box domains, 17.1.18
High-performance anion-exchange chromatography with pulsedamperometric detection (HPAE-PAD), of radiolabeled glycoconjugates, 12.2.14
High-performance liquid chromatography (HPLC)
in amino acid analysis, 11.9.1–11.9.2, 11.9.5, 11.9.7, 11.9.30–11.9.31
for ATP quantitation, 13.8.13
in automated C-terminal sequencing, 11.8.2, 11.8.6
capillary electrophoresis and, 10.9.1, 10.9.11, 10.9.12
using hydroxylapatite
matrices for, 8.6.2 (table)
of proteins and nucleic acids, 8.6.7–8.6.8, 8.6.10
in iodination product separation, 3.3.3–3.3.4, 3.3.17
laboratory equipment required, 1.1.5
in N-terminal sequencing, 11.10.4–11.10.5 (fig.), 11.10.21–11.10.25, 11.10.36 (table)
for peptide mapping, 7.3.2–7.3.5, 7.3.17–7.3.20, 7.3.22
properties of proteins as basis for, 1.1.4
of radiolabeled glycoconjugates, 12.2.14
of recombinant proteins
in contamination detection, 7.1.1, 7.1.2
with diode-array detector, 7.2.10–7.2.12, 7.2.15–7.2.16
interleukin 1β isolation, 6.2.12
primary structure determination, 7.1.3
in solubility determination, 6.2.11

γ-Interferon, mammalian cell production and specific growth rate, 5.9.12–5.9.13
Interleukin 2
folding and purification, 6.5.6–6.5.8, 6.5.20, 6.5.22–6.5.25
RP-HPLC of native and misfolded forms 6.5.8–6.5.9
Interleukin 5
characterization, 7.1.10
folding of, 6.1.16
Interleukin 1β
hydropathy profile, 2.2.7–2.2.8, 2.2.9 (fig.)
purification of recombinant
acid precipitation, 6.2.12
ammonium sulfate fractionation, 6.2.5–6.6.6, 6.2.12
clarifying lysate, 6.2.4–6.2.5
concentration and storage, 6.2.8, 6.2.9
dialysis of fractionated sample, 6.2.7
gel-filtration chromatography, 6.2.8–6.2.9
ion-exchange chromatography, 6.2.3, 6.2.5
lysis of cells, 6.2.3–6.2.4
monitoring, 6.2.13
osmotic shock, 6.2.13
recombinant vs. authentic, 6.2.12
salt fractionation, 6.2.13
scale of procedure, 6.2.13
strategy, 6.2.1–6.2.3
yield at various stages, 6.2.14
reversible unfolding transition, 6.4.3 (fig.)
secondary structure prediction
Chou and Fasman method, 2.3.4 (fig.)
comparison of methods, 2.3.11–2.3.18
Interleukin 2, mammalian cells for expression of, 5.9.13
Intermediate purification stage, in chromatography, 8.1.4
Internet
basics
connecting, 2.4.1–2.4.2
electronic mail, 2.4.1–2.4.8

Intranets, internet *vs.*, 2.4.15
Intrinsic tryptophan fluorescence, protein detection in polyacrylamide gels, 10.6.7
Invertase, 5.6.4 (fig.), 5.6.5 (table)
In vitro assay, of endosome fusion, 4.3.8, 4.3.15–4.3.16
Iodinated nonelectrolytes, in centrifugation media, 4.1.6
Iodinated solutes, gradient fractionation using
merits and limitations, 4.2.4
method, 4.2.20–4.2.22
Iodination
amount of isotope, 3.3.17
applications, 3.3.16
in density shift using colloidal gold conjugates, 4.2.42
in detection of tyrosine phosphorylation, 13.4.1–13.4.2 13.4.4–13.4.5
equimolar, 3.3.7
at lysine or N-terminus using Bolton-Hunter reagent, 3.3.9–3.3.11
in N-linked glycosylation, 12.3.5
oxidation in, 3.3.16
reactions, 3.3.2 (fig.)
sensitive amino acids, 3.3.17
separation of unlabeled peptides, 3.3.8–3.3.9, 3.3.17
strategy, 3.3.1–3.3.3
troubleshooting, 3.3.18 (table)
at tyrosine or histidine using chloramine T or iodogen, 3.3.5–3.3.6
Iodo-Beads, 3.3.3–3.3.5
lactoperoxidase, 3.3.6–3.3.7
Iodine, decontamination, A.2A.18
Iodoacetamide
radiolabeling via, 3.3.13
in recombinant protein stability, 6.1.16
Iodoacetic acid (IAA)
alkylation of cysteine residues using, 15.1.3, 15.1.15
properties, 15.1.2 (table)
purification of by recrystallization, 15.1.12–15.1.13
radiolabeling via, 3.3.13
Iodoacetyl-LC-biotin, 3.6.2 (table), 3.6.6–3.6.7, 3.6.11
N-Iodoacetyl-*N*′-(5-sulfo-1-naphthyl)ethylenediamine (IAEDANS)
for alkylation of cysteine residues, 15.1.2 (table), 15.1.3, 15.1.5
modification of proteins, 10.6.3–10.6.4, 10.6.6, 10.6.7 10.6.8
for protein labeling on blot transfer membranes, 10.8.5–10.8.6, 10.8.7
Iodo-Beads, iodination using, 3.3.3–3.3.5, 3.3.16
N-(iodoethyl)-trifluoroacetamide, modification of cysteine residues using, 15.1.2 (table), 15.1.7
Iodogen, iodination using, 3.3.5–3.3.6
Ion-exchange amino acid analysis, in cleavage of proteins in gels, 11.3.4
Ion-exchange chromatography
applications, 8.4.1, 9.6.14
batch adsorption
pH-based step-gradient elution, 8.2.13–8.2.14
step-gradient elution, 8.2.10–8.2.13
capacity optimization, 8.2.29
chromatogram of results, 8.2.29 (fig.)
column
capacity measurement and breakthrough capacity, 8.2.20–8.2.21
pH-based step-gradient elution, 8.2.14–8.2.16
coupling with other techniques, 8.2.25
gradient-formation techniques
autoblending, 8.2.22
multichannel peristaltic pumps, 8.2.22, 8.2.23 (fig.)
profile construction, 8.2.28–8.2.29
simple mixers, 8.2.21, 8.2.22 (fig.)
switch-valve-based mixing, 8.2.22–8.2.23
twin pumps, 8.2.22
in iodination product separation, 3.3.17
media cleaning and regeneration, 8.2.23–8.2.24
pH in protein charge, 8.2.1
properties of proteins as basis for, 1.1.4
in purification strategy
capture stage, 8.1.3–8.1.4
intermediate stage, 8.1.4
of recombinant proteins
bovine growth hormones, 6.5.4–6.5.5
contamination in, 6.1.17
equipment, 6.1.18–6.1.19
vs. hydroxylapatite, 8.6.9–8.6.10
insoluble, 6.1.14
interleukin 1β, 6.2.3, 6.2.5, 6.2.12
stages, 6.1.9 (fig.), 6.1.10
resolution optimization, 8.2.25–8.2.29
storage of media, 8.2.24–8.2.25
strategic planning
batch vs. column techniques, 8.2.3–8.2.4
buffer system selection, 8.2.2–8.2.3
equipment, 8.2.8–8.2.9
medium selection, 8.2.2, 8.2.4, 8.2.5–8.2.7 (table), 8.2.8
scale-up conditions, 8.2.9–8.2.10
solution preparation, 8.2.8
steps, 8.2.2–8.2.4
test tube pilot experiment to determine starting conditions 8.2.16–8.2.19
troubleshooting guide, 8.2.27–8.2.28 (table)
yield, 8.1.3 (table)
Ion-exchange media
anion vs. cation, 8.2.2
for batch adsorption, 8.2.4 (table)
capacity of, 8.2.4, 8.2.8
cleaning and regeneration, 8.2.23–8.2.24
for column purification, 8.2.5–8.2.7 (table)
regenerating, 8.2.13
in resolution, 8.2.28–8.2.29
storage, 8.2.24–8.2.25
Ionic detergents, A.1B.2
Ionic strength, in
aggregation, 6.4.6
ion-exchange chromatography
batch adsorption, 8.2.10–8.2.13
chromatographic titration curve, 8.2.25, 8.2.26 (fig.), 8.2.28
gradient-formation techniques, 8.2.21–8.2.23
test tube experiment to determine, 8.2.16–8.2.19
Ionization methods, for mass spectrometry, 16.1.2 (table)
IPG gels, *see* Immobilized pH gradient gels
IPL-41 medium, 5.5.16
IPTG, *see* Isopropyl-β-D-thiogalactopyranoside
Iron-dextran conjugates, 4.2.48
Isoelectric focusing (IEF)
by capillary electrophoresis, 10.9.5
to determine charge heterogeneity, 7.3.13–7.3.15
one-dimensional electrophoresis
applications of, 10.2.6
in denaturing slab gels, 10.2.1–10.2.4
electroblotting from denaturing slab gels, 10.2.4
fluorography of denaturing slab gels, 10.2.5, 10.2.7
of immune complexes, 10.2.7
nonequilibrium gels, 10.2.8

FOR PERSONAL USE ONLY / CENTRAL UNIVERSITY LIBRARY

polymerization in, 10.2.7
SDS in, 10.2.7
vs. SDS-PAGE, 10.2.6–10.2.7
staining of gels, 10.2.7
for phosphorylation studies, permeabilization for, 13.8.7, 13.8.9
of recombinant proteins, in primary structure characterization, 7.1.2
two-dimensional electrophoresis, 10.2.7
high-resolution equilibrium in tube gels, 10.4.2–10.4.7
immobilized pH gradient gels, 10.4.13–10.4.16, 10.4.32–10.4.34
immobilized pH gradient gel strips, 10.4.9–10.4.13
investigator 2D gel system, 10.4.33
molecular weight standards preparation, 10.4.24
nonequilibrium of very acidic proteins, 10.4.8, 10.4.32
nonequilibrium of basic proteins, 10.4.8–10.4.9, 10.4.32
pH profile measurements, 10.4.7
using soluble ampholytes, 10.4.31–10.4.32
tissue culture cell extracts, 10.4.17–10.4.19
tissue sample preparation, 10.4.19
tube gels, 10.4.20–10.4.22
in X-ray crystallography sample preparation, 17.3.7
Isoelectric point (pI)
in aggregation, 6.4.6
in capillary electrophoresis, 10.9.4, 10.9.7, 10.9.11
in chromatofocusing, 8.5.1
electrophoresis based on, 10.2.1
HPLC and, 10.9.1
in hydroxylapatite chromatography, 8.6.9
in ion-exchange chromatography, in medium selection, 8.2.2
methods based on, 1.1.4
in nondenaturing electrophoresis, 10.3.9–10.3.10
pH effects and protein charge, 8.2.1
of recombinant proteins, 6.1.2, 6.1.7
standards, 10.4.7
Isoionic precipitation of proteins
column method, 4.5.9–4.5.12
dialysis method, 4.5.12
isoionic point, definition, 4.5.9
resins for, 4.5.9–4.5.10, 4.5.29
Isomerization, in folding, 6.4.1, 6.4.6
Isoprenoid biosynthetic pathway
biochemistry of, 14.3.8–14.3.9
groups used in post-translational modification, 14.3.8 (fig.)
radiolabeling of intermediates
in vitro, 14.3.3–14.3.4. 14.3.9–14.3.10
in vivo, 14.3.1–14.3.2, 14.3.9–14.3.10
Isopropanol, in enzymatic digestion of proteins in solution 11.1.2 (table)
Isopropyl-β-thiogalactopyranoside (IPTG), *lac* promoter system induction, 5.1.2, 5.2.4, 5.2.14–5.2.15
Isopropyl-1-thio-β-D-galactopyranoside (IPTG)
induction of GST fusion protein expression with, 6.6.5–6.6.7, 6.6.20
recipe, 6.6.17
Isopycnic density gradient centrifugation, 4.1.2
Isothermal titration, of recombinant proteins, 7.1.4 (table)
Isotopes
effect on accuracy of mass spectrometry, 16.1.17–16.1.22
mass and abundance values, 16.1.18 (table), A.1A.2
Isotopic labeling, *see* Radiolabeling

J

Jackalin, in glycoprotein purification, 9.1.3 (table)
JPEG (Joint Photographic Experts Group), 10.12.7

K

Kanamycin phosphotransferase, 6.3.13
Kanamycin resistance gene, 5.7.5, 5.7.6 (table), 5.7.8, 5.7.10 (fig.)
Karlin-Altshul (K-A) statistics, 2.5.30
KDEL salvage pathway in mammalian cells, 5.9.9, 5.9.10
Keratan sulfate chains, 12.3.8
Keratin, as contaminant in silver staining, 10.5.11
Ketose, defined, 12.1.7
KEX2 gene, 5.6.6
Keyhole limpet hemocyanin (KLH), as carrier protein inantibody production, 18.3.1, 18.3.8–18.3.9
K homology domain, 17.1.22
Kinases
assays for
activity, defined, 13.7.20
assay conditions, 13.7.4
ATP concentration, importance of, 13.7.21
Ca^{2+}/calmodulin-dependent (CaM) kinases, 13.7.9–13.7.10
casein kinases, 13.7.7–13.7.9
cell lysates for, preparation, 13.7.14
controls, 13.7.21
cyclic nucleotide–dependent kinases, 13.7.4–13.7.5
direct analysis of cytosolic or membrane-bound, 13.8.10
enzymes, 13.7.1–13.7.2, 13.7.3 (table), 13.7.21
in-gel kinase assays, 13.7.12–13.7.13
P81 phosphocellulose paper, use of, 13.7.15–13.7.17
peptides as substrates for, 13.7.3, 13.7.20, 13.7.21
permeabilization for phosphorylation studies, UNIT 13.8
protein kinase C isoforms, 13.7.6–13.7.7
substrates, choice of, 13.7.2–13.7.3, 13.7.20
tyrosine kinases, 13.7.11–13.7.12
phosphorylation and
activation and inhibition, 13.1.1, 13.1.3
detection of phosphoproteins, 13.5.5, 13.5.6
labeling studies, 13.1.1
post-translational modifications in insect cells, 5.4.3
in recombinant expression systems, in folding, 6.1.16
structure, 17.1.11–17.1.12
Kinetic assays of enzymes
binding studies, 3.5.8
buffer for reaction, selection of, 3.5.3
continuous vs. stop-time, 3.5.7
coupled, 3.5.7–3.5.8
design of
enzyme concentration, 3.5.5
reaction conditions, 3.5.2–3.5.3
stability and purity of enzyme, 3.5.4–3.5.5
stability and purity of substrate, 3.5.3–3.5.4
substrate concentration, 3.5.5–3.5.7
initial-rate data, presentation of
double-reciprocal plots, 3.5.6 (fig.), 3.5.8–3.5.9
Eisenthal–Cornish-Bowden plots, 3.5.8–3.5.9
metal-ion concentrations for reaction, 3.5.3
Michaelis constant, estimation of, 3.5.5–3.5.7
multisubstrate systems, 3.5.6–3.5.7
progress curves for
regions of, 3.5.1–3.5.2
typical, 3.5.2 (fig.)
Scatchard plots in, 3.5.8
steady-state in, 3.5.1–3.5.2, 3.5.5
temperature for reaction, 3.5.2
Kinetics
of expression in baculovirus system, 5.5.4–5.5.5
of growth in *E. coli* fermentation, 5.3.17 (fig.)
Kjeldahl method, 3.4.15
KLH, *see* Keyhole limpet hemocyanin
KM71 *P. pastoris* strain, 5.7.3 (table), 5.7.4
Kringle domain, 6.1.1
Kyte and Doolittle hydropathy scale
applications of, generally, 2.1.13, 2.2.2–2.2.3, 2.2.4 (table), 2.2.6 (fig.), 2.2.7–2.2.9, 2.2.10 (fig.), 2.2.11 (fig.)
for peptide sequences in antibody production, 18.3.2–18.3.4, 18.3.15

L

Labeling
biosynthetic, with fatty acids, 14.2.1–14.2.3
biotin
on carbohydrate groups, 3.6.8–3.6.9
on cell surfaces, 3.6.4–3.6.6
detection, 3.6.10, 3.6.12
at lysine residues, 3.6.1–3.6.1–3.6.4, 3.6.11
media for, 3.6.14
reaction, 3.6.3 (fig.)
reagents for, 3.6.2 (table), 3.6.11–3.6.12, 3.6.13
of endosomal carrier vesicle fusion with gold particles, 4.3.16
glycoproteins, 12.4.6–12.4.7

soluble proteins, 6.1.6 (fig.), 6.1.7, 6.1.10, 6.2.11, 6.2.13–6.2.14
Lysis of cells, for immunoblotting, 13.4.1
Lysosome-Associated Membrane Protein (LAMP-1),glycosylation sites, 12.4.7 (fig.)
Lysosomes
density gradient centrifugation in nonionic solutes, 4.2.47
density shift using colloidal gold conjugates, 4.2.41
deuterium oxide fractionation, 4.2.46–4.2.47
as endocrine secretion granule contaminant, 4.2.19
fractionation, 4.1.8 (table)
gradient fractionation using nonionic iodinated solutes, 4.2.20–4.2.22
latency, 4.3.7
subcellular fractionation, UNIT 4.3
Lysozyme, endoproteinase digestion of, 11.1.6 (table)
Lysozymes
hydropathy profiles of, 2.2.2 (fig.), 2.2.6 (fig.)
T7, 5.2.14
Lysozyme treatment, of recombinant expression systems
applications, 6.1.7, 6.1.8 (fig.), 6.1.12–6.1.13
bovine growth hormone, 6.5.2–6.5.3
inclusion body extraction, 6.3.1–6.3.2
interleukin 1β, 6.2.4
Lysyl endopeptidase, in digestion in gels, 11.3.1, 11.3.4, 11.3.7–11.3.8

M

MACAW (software), 2.1.8
α-Macroglobulin, 6.1.7
Macromolecular crystallization
crystallographic analysis, optimization of equilibration conditions, 17.4.14–17.4.16
parameters, 17.4.12–17.4.14
defined, 17.4.16
macromolecular complexes, preparation of, 17.4.3–17.4.4
nucleic acid fragments, preparation of, 17.4.2–17.4.3
protein preparation, 17.4.1–17.4.2
salt composition, analysis of
using cryoloop, 17.4.10–17.4.11
using filtration, 17.4.11
trials, preparation and analysis of, 17.4.4–17.4.9
vapor-diffusion technique, 17.4.16–17.4.17
Macro-Prep matrices, 8.4.2 (table)
Macro-Prep media, 8.2.5–8.2.6 (table)
MacVector (software), 2.3.13 (table)
MAD, *see* Multiwavelength anomalous diffraction
MADS box domain, 17.1.16

Magnetic beads
in immunoisolation, 4.3.9–4.3.10, 4.3.14
in solid-phase immunoadsorption, 4.2.29–4.2.33, 4.2.48
Magnetic-affinity cell sorting, generally, 5.10.8
Major histocompatibility complex class II molecules, 4.2.30 (fig.), 4.2.47
Major histocompatibility complex (MHC) peptide-bindingfold, 17.1.5
MAL, in glycoprotein purification, 9.1.2 (table)
MALDI-MS, *see* Matrix-assisted laser-desorption/ionization mass spectrometry
MALDI-TOF, *see* Matrix-assisted laser-desorption/ionization time-of-flight mass spectrometry
m-Maleimidobenzoyl-*N*-hydroxysuccinimide ester (MBS), for coupling synthetic peptides to carrier proteins, 18.3.5–18.3.6, 8.3.8–18.3.9, 18.3.10 (fig.), 18.3.15–18.3.16
Maltose-binding protein, in fusion protein systems
generally, 5.1.4
for soluble protein expression, 6.7.10
Mammalian cells
Mammalian cells, recombinant cell production
applications and features, 5.9.1, 5.9.14–5.9.15
background sensitivity to G418, determination of, 5.10.8
cell banks, freezing cells for production of, 5.10.23
cell growth
in batch mode in large-scale spinner culture vessels, 5.10.14–5.10.17
in continuous culture in bioreactors, 5.10.19–5.10.20
graphical determination of, 5.10.24
in large-scale batch reactors, 5.10.17–5.10.18
mechanisms of, 5.10.31–5.10.34
numerical determination of, 5.10.24
productivity and, 5.10.37
shaker flask growth curve, 5.10.26–5.10.27
cell lines, choice of, 5.10.31
choice of host, 5.9.1–5.9.5
cloning, single-cell, 5.10.9–5.10.10
culture of cells for protein expression, 5.9.10–5.9.13
dihydrofolate reductase (DHFR), amplication with methotrexate (MTX), 5.10.10–5.10.11
flow chart of, 5.9.2 (fig.)
GFP, screening by flow cytometry, 5.10.8–5.10.9
glycosylation in, 5.6.5
harvesting of protein product from batch-mode spinnercultures and large-scale batch reactors
cell-associated products, 5.10.22
secreted products, 5.10.21–5.10.22
expression vector construction, 5.10.34
heterologous protein production
graphical determination of, 5.10.25, 5.10.38 (table)
numerical determination, 5.10.25, 5.10.38 (table)
organelle purification, UNIT 4.2
plasmid purification by alkaline-lysis/anion-exchange capture, 5.10.3–5.10.5
quantity produced by specific systems, 5.9.13 (table)
requirements for analyses, 5.9.14 (table)
samples, preparation for product assay, 5.10.26
scale of operation, 5.9.13–5.9.14
secreted products, 5.10.21–5.10.22, 5.10.30–5.10.31
selection process, for neomycin phosphotransferase (NPTII)with geneticin, 5.10.7–5.10.8, 5.10.28–30
shaker flask growth curve, determination of, 5.10.26–5.10.27, 5.10.36
specific productivities, 5.10.35–5.10.37, 5.10.38 (table)
suspension cells, adaptation to production medium throughmultiple passaging, 5.10.1–5.10.2, 5.10.12–5.10.14, 5.10.31
transfection of cells
generally, 5.10.1, 5.10.5–5.10.6, 5.10.34–5.10.35
selection, and amplification, 5.9.5–5.9.6
translation, quality control, and covalent modification, 5.9.6–5.9.10
Mammalian cell culture, APPENDIX 3C
Mammalian expression systems, applications, 6.1.2
Manganese, in phosphatase stimulation, 13.5.8
Mannitol, as centrifugation media, 4.1.5
Mannosamine, 12.5.10
D-Mannose
chair conformation, 12.1.6 (fig.)
defined, 12.1.7
in mammalian cells, 5.6.5
radiolabeling via, 12.2.12
Mannosidases, 12.3.2 (table), 12.3.3 (fig.), 12.3.8
Manton-Gaulin-APV homogenizer, 6.1.7, 6.1.18, 6.5.22
Manual inspection for sequence selection, 18.3.4, 18.3.5 (table), 18.3.15
MAP, *see* Multiple antigenic peptide (MAP)
Mapping, peptide
by high-resolution SDS-PAGE, 7.3.5–7.3.6, 7.3.17–7.3.22
by HPLC, 7.3.2–7.3.5, 7.3.17–7.3.20, 7.3.22
by mass spectrometry, 7.3.18
Markers
in chromatofocusing, 8.5.6
enzymatic, for subcellular fractionation, 4.3.1–4.3.3, 4.3.14
in gel-filtration chromatography, 6.1.19, 6.2.8
in mammalian cell expression systems, 5.9.5–5.9.6
in organelle purification
density gradient electrophoresis, 4.2.30 (fig.)
density shift using digitonin, 4.2.35, 4.2.38 (fig.)
electrophoresis, 4.2.47
fractionation, 4.1.7–4.1.8
gel filtration, 4.2.24 (fig.)
gradient fractionation using nonionic iodinated solutes, 4.2.22
lectin adsorption, 4.2.34, 4.2.35, 4.2.51
zonal centrifugation, 4.2.15 (fig.)
Mass balance, quantitative amino acid analysis incompiling, 3.2.1–3.2.2
Mass fingerprinting, 11.10.34–11.10.36
Mass spectrometry
accuracy and resolution of, 16.1.17–16.1.22
in bovine growth hormone folding, 6.5.23
ESI-MS, 16.1.10–16.1.15
fast atom bombardment, 16.1.3
and gel-filtration chromatography, 8.3.17–8.3.18, 8.3.25
ionization methods for, 16.1.2 (table), 16.1.3–16.1.4
ions produced by, 16.1.5 (fig.) (table)
MALDI
matrix fast-evaporation method for peptide mapping, 11.6.8–11.6.9
N-terminal sequencing and, 11.10.2, 11.10.11, 11.10.31–11.10.32, 11.10.34–11.10.36
peptide mapping, 11.6.7–11.6.8
theory and techniques, 16.1.6–16.1.10, UNIT 16.2
mass analyzers
quadrupole, 16.1.10–16.1.12, 16.1.15
time-of-flight (TOF), 16.1.7–16.1.8, UNIT 16.2
sensitivities of, compared, 16.1.3
molecular weight determination by, 16.1.8 (fig.)
MS/MS, 16.1.4–16.1.6
plasma desorption, 16.1.3
protein quantitation by, 16.1.16–16.1.16
of recombinant proteins
in contamination detection, 7.1.1
post-translational modification determination, 7.1.3, 7.1.10
primary structure determination, 7.1.3
resolution of, 16.1.19–16.1.20 (figs.)
sample preparation for, 16.1.16–16.1.17
World Wide Web sites for, 16.2.8 (table)

MOSAIC (software), 2.1.14
Motifs, 2.1.12, 2.1.13 (fig.)
Mouse, antigen formation in, 5.9.9
Mouse endocrine secretion granules, gradient fractionation, using deuterium oxide, 4.2.18–4.2.19
Mouse monoclonal antibodies, 4.2.48, 8.6.8 (fig.)
MPD (2-methyl-2,4-pentanediol), 4.5.15, 4.5.31
MPEG (Moving Picture Experts Group), 10.12.7
MRC-5, for recombinant protein expression, 5.9.3 (table), 5.9.4
MS, *see* Mass spectrometry *and specific techniques*
Mucin, defined, 12.1.7
Multiangle low-angle light scattering (MALLS)
calibration, 7.8.6
defined, 7.8.1, in
gel-filtration chromatography, 8.3.17–8.3.18, 8.3.25
measurement of, 7.8.3–7.8.4
molecular weight, evaluation of, 7.8.6–7.8.7
normalization, 7.8.6
radius of gyration, 7.8.7
size exclusion chromatography (SEC-MALLS)
defined, 7.8.4
experimental setup for, 7.8.5 (fig.)
molecular weight distribution, evaluation of, 7.8.7–7.8.8 (fig.)
Multipin techniques for peptide synthesis
apparatus, 18.2.2 (fig.), 18.2.3 (table), 18.2.3–18.2.5
development of, 18.2.16
ELISA, 18.2.17, 18.2.18 (fig.)
flow chart, 18.2.2 (fig.)
Fmoc-protected amino acids for, preparation, 18.2.13–18.2.14
kits, 18.2.3–18.2.5
N-terminal
acetylation of peptides, 18.2.14–18.2.15
biotinylation of peptides, 18.2.15
planning for, 18.2.3–18.2.5
procedure, 18.2.5–18.2.13, 18.2.16–18.2.17
software (Pepmaker), 18.2.5, 18.2.8–18.2.11 (figs.)
Multiple alignments in sequence analysis, 2.1.8–2.1.10
Multiple antigenic peptide (MAP), designing, 18.3.1, 18.3.7–18.3.8, 18.3.16
Multiple gel caster, 10.1.23–10.1.26
Multiple isomorphous replacement, in X-ray crystallography, 17.3.2
Multiplicity of infection (MOI), in baculovirus expression system, 5.5.3, 5.5.15, 5.5.16
Multiply deficient medium (MDM)
composition, 12.2.5 (table)
in glycoconjugate labeling, 12.2.3–12.2.4
preparation and supplementation, 12.2.9
stock solutions for reconstitution, 12.2.8 (table)
Multiprotein-nucleic acid complexes, crystallization of, 17.4.4
Multiwavelength anomalous diffraction (MAD), of recombinant proteins, 5.3.15
Multiwavelength anomalous dispersion (MAD), 17.3.3
Murine cells, *see* Mouse
Muscle movement proteins, 17.1.32–17.1.33
Mut^+ Mut^S, 5.7.2 (table), 5.7.3, 5.7.6, 5.7.14, 5.8.9, 5.8.14, 5.8.15
Mutagenesis
in recombinant protein purification, 1.2.3–1.2.4
of X-ray crystallography samples, 17.3.12–17.3.13
Mutant proteins, conformational analysis, 7.1.8
Mutations, circular dichroism analysis, 7.6.20 (fig.), 7.6.21
Myeloma cells, for recombinant protein expression, 5.9.3 (table), 5.9.4
Myoglobin
adsorptive losses of, 11.10.9 (table)
in chromatofocusing, 8.5.10 (fig.)
hydropathy profile, 2.2.5–2.2.7, 2.2.10 (fig.)
Myohemerythrin, electron density, 17.3.4 (fig.)
Myosin subfragment 1, 17.1.42
Myristic acid
acylation of proteins with, biochemistry of, 14.2.6–14.2.9
identification in labeled cells by TLC, 14.2.5 (fig.)
radiolabeled, in analysis of acylation, 14.2.1–14.1.3
structure of, 14.2.7 (fig.)
Myristylation, in insect cells, 5.4.3

N-terminal sequence analysis, UNIT 11.10
reversed-phase isolation of, UNIT 11.6
signal, in mammalian expression systems, 5.9.7–5.9.8
solid phase synthesis of
analytical techniques for monitoring, 18.1.6
carbohydrate groups, incorporating, 18.1.6
coupling reagents, 18.1.4–18.1.5
disulfide bonds, incorporating, 18.1.6
instruments for, 18.1.4 (table)
modified residues, incorporating, 18.1.5–18.1.6
multipin techniques, UNIT 18.2
reactions in, 18.1.2 (table)
reagents for, 18.1.5 (table)
solid support for, 18.1.3–18.1.4
synthesis of, 10.9.12
synthetic, for production of antibodies, UNIT 18.3
tyrosine-phosphorylated
antibodies against, producing, 13.6.1–13.6.6, 13.6.11
coupling to affinity columns, for purifying anti-phosphopeptide antibodies, 13.6.7–13.6.8
synthesis of, for producing anti-phosphopeptide antibodies, 13.6.1, 13.6.6
See also Polypeptides
Peptidoglycans, in recombinant expression systems, 6.1.46.1.11–6.1.13
Peptidyl prolyl *cis-trans* isomerase, 6.4.1, 6.4.6
Perchloric acid, in protein precipitation, 4.5.20, 4.5.32
Percoll (polyvinylpyrrolidone-coated colloidal silica)
fractionation of tissue homogenates using merits and limitations, 4.2.2–4.2.3
method, 4.2.14–4.2.17
properties of, 4.1.6–4.1.7
subcellular fractionation of tissue culture cells using, 4.3.13 (table)
Performic acid, oxidation of cysteine residues using, 15.1.2 (table), 15.1.10
Perfusion culture, insect cell–recombinant baculovirus production in, 5.5.7–5.5.8, 5.5.15
Peripheral membrane proteins
purification strategies, 1.2.2–1.2.3
as structural classification, 1.2.1 (table)
Periplasmic extracts, of recombinant proteins, 5.2.11, 5.2.15
Periplasmic space, recombinant expression systems in, 6.1.5–6.1.7
Peristaltic pumps, for gradient mixing, 8.2.22, 8.2.23 (fig.)
Perkin-Elmer Procise Sequencer
installing HPLC restricter loop, 11.10.24–11.10.25
optimizing PTH amino acid separation, 11.10.21–11.10.24
sample cartridges, 11.10.4–11.10.5 (fig.)
sequencing liquid samples on glass fiber filters, 11.10.12–11.10.16, 11.10.37
Permeabilization for phosphorylation studies
applications, 13.8.1–13.8.2
autoradiography in analysis, 13.8.19
using cells
for electrophoretic analysis, 13.8.6–13.8.7, 13.8.19
for immunoprecipitation analysis, 13.8.2–13.8.6, 13.8.19
direct analysis of cytosolic or membrane-bound kinases, 13.8.10
using isolated subcellular fractions
for electrophoretic analysis, 13.8.9, 13.8.19
for immunoprecipitation analysis, 13.8.7–13.8.9, 13.8.19
optimizing, 13.8.18–13.8.19
specific radioactivity of ^{32}P-containing compounds determination, 13.8.11–13.8.15
Peroxide, 4.3.7
Peroxisomes
density gradient centrifugation in nonionic solutes, 4.2.47
deuterium oxide fractionation, 4.2.47
fractionation, 4.1.8 (table)
gradient fractionation using nonionic iodinated solutes, 4.2.22
pGEX vectors
expression of GST fusion proteins using, 6.6.1–6.6.7, 6.6.19
map, 6.6.3 (fig.)
polylinker site, 6.6.4 (fig.)
pH
in capillary electrophoresis, 10.9.4–10.9.5
in chromatofocusing, 8.5.1–8.5.3, 8.5.4 (table), 8.5.5 (table)
in Coomassie dye–binding assay, 3.4.10, 3.4.21
effect on electroosmotic flow, 10.9.4
effect on UV absorption spectra, 3.4.7 (fig.), 3.4.20
in electrophoresis, of phosphoamino acids, 13.3.2, 13.3.3 (fig.), 13.3.4 (fig.), 13.3.5 (fig.), 13.3.7
in folding, 6.4.5
in gel electrophoresis
IEF, 10.2.1
nondenaturing, 10.3.1, 10.3.9–10.3.10
in hydroxylapatite chromatography, 8.6.4, 8.6.9, 8.6.10, 8.6.11
immunoaffinity chromatography, 9.5.4–9.5.5
in hydrophobic-interaction chromatography, 8.4.4–8.4.58.4.16, 8.4.19
in ion-exchange chromatography
batch adsorption, 8.2.11
buffer system, 8.2.2
chromatographic titration curve, 8.2.25, 8.2.26 (fig.)
column chromatography, 8.2.15
gradient-formation techniques, 8.2.21–8.2.23
medium selection, 8.2.2, 8.2.8
step-gradient elution, 8.2.13–8.2.14
test tube experiment to determine, 8.2.16–8.2.19
in mammalian cell culture, 5.9.13–5.9.14
in organelle purification
differential centrifugation by equilibrium, 4.2.11
gradient fractionation using nonionic iodinated solutes, 4.2.20
of phosphatases, 13.5.3
in protein charge, 8.2.1
in recombinant protein expression systems
inclusion body extraction, 6.3.8
ion-exchange chromatography, 6.1.10, 6.2.5
metal-chelate affinity chromatography, 6.5.12
purification, 6.2.14
in stability of proteins, 6.1.17
in ultrafiltration, 6.2.8
urea modification of proteins and, 11.10.8
PHA, in glycoprotein purification, 9.1.2 (table)
Phage tail spike protein mutants, 6.4.2
Pharmacological agents, phosphorylation studies, 13.8.5
Pharmalyte, 8.5.3
Phase in X-ray crystallography, 17.3.1–17.3.3
PHD, *see* EMBL Profile Neural Network
Phenolic compounds, Folin assay for, 3.4.16
Phenol–sulfuric acid neutral sugar, calibration plots for spectrophotometric assays, 3.4.17 (table)
Phenylalanine, in spectrophotometric determination of protein concentration
absorbance, 3.1.1–3.1.2, 3.1.4–3.1.6, UNIT 7.2
contribution to circular dichroism spectra, 7.6.1, 7.6.16
fluorescence emission, 3.1.3, 3.1.4–3.1.5
transitions of, electronic, 7.6.1, 7.6.16 (table)
Phenylisothiocyanate (PITC)
as blocking reagent, 11.7.8–11.7.9
in N-terminal sequence analysis, 11.10.1–11.10.2, 11.10.4–11.10.5 (fig.), 11.10.34
Phenylmethylsulfonyl fluoride (PMSF), 6.5.22, 12.5.10, A.2A.20–A.2A.21
4-Phenylspiro[furan-2 (3*H*), 1′-phthalan]-3,3′-
dione *see* Fluorescamine
Phenylthiocarbamyl derivitization, 11.9.3, 11.9.4–11.9.16
Phenylthiohydantoin (PTH) amino acid analysis
using biphasic cartridge sequencer, 11.10.19, 11.10.20–11.10.21
expected recoveries of, 11.10.26, 11.10.29, 11.10.30 (table)
instrumentation, 11.10.4–11.10.5 (fig.)
using liquid samples on glass fiber filters, 11.10.14–11.10.15
optimizing separation for, 11.10.21–11.10.25
process, 11.10.1–11.10.1
using PVDF-bound samples and Blott cartridge, 11.10.16
PHO5 promoter, 5.6.2, 5.6.4 (fig.)
Phosphatase inhibitors, 13.5.2
applications, 13.1.3–13.1.4
Phosphatases
labeling studies, 13.1.1–13.1.2
in phosphorylation detection
acid phosphatase digestion, 13.5.2–13.5.3
alkaline phosphatase digestion, 13.5.3
applications, 13.5.1
^{32}P measurement and identification, 13.5.5, 13.5.6
properties of enzymes, 13.5.5–13.5.8
protein serine/threonine phosphatase digestion, 13.5.3–13.5.4
protein tyrosine phosphatase digestion, 13.5.5
strategy, 13.5.1–13.5.2
regulation of, 13.1.3–13.1.4
role of, 13.1.1
structure, 17.1.12
types of, 13.1.3

Phosphate, in hydroxylapatite chromatography, 8.6.4, 8.6.9, 8.6.10, 8.6.11
Phosphate nondenaturing polyacrylamide gels, 10.3.3 (table)
Phosphatidylinositol-specific phospholipase C, *see* Phospholipase C
Phosphoamino acids
  acid hydrolysis and two-dimensional electrophoresis, 13.3.1–13.3.5, 13.3.7–13.3.8
  alkali hydrolysis for Tyr- and Thr-phosphorylated proteins blotted onto filters, 13.3.6, 13.3.7–13.3.8
  quantitation of, 11.9.26–11.9.27
Phosphocellulose, 6.1.10
Phosphocellulose paper, P81, 13.7.15–13.7.17, 13.7.21
Phosphoimaging, two-dimensional gel electrophoresis, 10.4.26
Phospholipase C
  in cleavage of GPI-containing proteins, 12.5.5–12.5.7, 12.5.11–12.5.12
  hydrophobic-interaction chromatography of, 8.4.16
Phospholipase D, 12.5.5–12.5.7, 12.5.11–12.5.12
Phosphopeptides, production of antibodies against,UNIT 13.6
Phosphoric acid, in Coomassie dye–binding assay, 3.4.21
Phosphorylase *a*, 13.1.1
Phosphorylase B, 11.10.9 (table)
Phosphorylation
  dephosphorylation, inhibiting following lysis, 13.2.7
  enzymatic techniques, UNIT 13.5
  immunological techniques in detection of, UNIT 13.4
  inhibiting following lysis, 13.2.7
  kinase assays, UNIT 13.7
  kinases, 13.1.3
  labeling studies, 13.1.1–13.1.2
  permeabiliation strategies for study of, UNIT 13.8
  phosphatases, 13.1.3–13.1.4
  phosphoamino acid analysis
    with labeling, UNIT 13.3
    without labeling, 13.1.2
  $^{32}P_i$ labeling and lysis for immunoprecipitation, UNIT 13.2
  role of, 13.1.1
  sites, 13.1.2
  two-dimensional gel electrophoresis, 10.4.30
Phosphoryl chloride, in activating matrix hydroxyl function 9.3.2 (table)
Phosphotransferases, gel filtration of, 6.3.13
Phosphotyrosine, 13.6.8–13.6.9
Photochemical methods, for coupling synthetic peptides to carrier proteins, 18.3.6, 18.3.13
Photography, of proteins in polyacrylamide gels, 10.5.8–10.5.9
Photopolymerization catalysts, 7.4.1–7.4.2, 7.4.5, 7.4.8
o-Phthalaldehyde, in chemical cleavage on membranes, 11.5.3
Phycocyanins, 17.1.40
Phylogenetic trees, 2.1.10, 2.1.11 (fig.)
Physical appearance, of recombinant proteins, characterizing, 7.1.3, 7.1.5
pI, *see* Isoelectric point
$^{32}P_i$ in phosphorylation studies
  vs. [^{125}I]protein A, 13.4.1
  kinases vs. phosphatases, 13.1.1–13.1.2
  labeling procedures
    cell and isotope amounts, 13.2.6
    for cultured cells, 13.2.1–13.2.2
    lysis by boiling in SDS, 13.2.4
    lysis with mild detergent, 13.2.2–13.2.4
  measurement and identification of release, 13.5.5, 13.5.6, 13.5.8
  phosphatase vs. protease, 13.1.1–13.1.2
  in phosphoamino acid analysis, UNIT 13.3
  safety considerations, 13.1.1
  specific radioactivity determination, 13.2.14–13.8.15

[γ-^{32}P]ATP solution, 13.7.18
avidin buffer, 3.6.10
basal salts solution, 5.8.11
basic protein sample buffer, 7.4.5
BCA reagents, 3.4.13–3.4.14
biotin-cellulose
binding buffer, 9.7.9
elution buffer, 9.7.9–9.7.10
biuret reagent, 3.4.14
blocking buffers, for colorimetric and luminescent immunoblot detection, 10.10.7
bovine growth hormone
break buffers, 6.5.14
column buffers, 6.5.15
extraction buffer, 6.5.15
folding buffers, 6.5.15–6.5.16
wash buffer, 6.5.16
3-bromopropylamine, 15.1.15
BSSM fermenter medium, 5.8.11
buffer TM, 9.6.11
buffer Z, 9.6.11
buffer Ze, 9.6.12
CAA/glycerol/ampicillin 100 medium, 6.7.9
CaM kinase reaction buffer, 13.7.18

Reagents and Solutions (continued)

cA-PrK assay buffer, 13.8.16
carbonate developing solution, 10.5.10
Casamino acids, 5.8.11, 6.7.9
casein kinase reaction buffer, 13.7.18
cathode buffer, 10.1.27
cation-exchange buffer, 10×, 6.2.9
chase medium, 14.1.9
chromogenic visualization solutions, 10.10.8
CNBr, 9.3.7–9.3.8
  5 mg/ml in formic acid, 11.4.4–11.4.5
CNBr/acetonitrile, 9.5.8
cold ATP stock solution, 13.8.16
column buffer, 9.1.8
column regeneration buffer, 9.6.12
column storage buffer, 9.6.12
column storage solutions, 9.5.8
commonly used buffers and stock solutions, A.2E.1–A.2E.5
Coomassie blue staining solution
  G-250, 10.1.27
  acid-based, 10.5.9
  R-250 for fixing and staining in PAGE gels, 10.5.10
  R-250 for staining in urea gels, 7.4.5
Coomassie dye reagent, 3.4.14
coupling buffer, 3.6.11
cyanide detection reagent, A.2A.24
cyanogen bromide, 2 mg/ml in 70% formic acid, 7.3.16
cyclic nucleotide–dependent protein kinase reaction buffer, 13.7.18
cycloheximide, 14.1.10
cysteine, 1 M, 14.1.10
cysteine standard stock solution, 15.1.15, 18.3.14
DEPC treatment of solutions and labware, 14.1.10
depletion medium, 14.1.10
detector flow cell, 11.6.10
detergent lysis buffer, 5.5.14
detergent stock solutions, 9.5.8
dialysis tubing, pretreated, 7.3.16
digestion buffer, for peptide mapping, 7.3.16
digestion buffer, for PVDF-bound proteins, 11.2.4
digitonin density shift gradient stock solutions, 4.2.43
digitonin stock solution (20 mg/ml), 4.2.43
diisopropylfluorophosphate (DFP) solution, 1%, 11.2.4
dioxetane phosphate substrate buffer, 10.10.8
dithiothreitol (DTT), 1 M, A.2E.1
DLM medium, 5.3.12
DMEM, complete, A.3C.11
DMEM/F12 custom-modified medium, 5.10.27
DMSO/PPO solution, 10.2.6
DNase and RNase solution, 10.4.27
DNase I solution, 9.4.11
DryStrip equilibration solutions, 10.4.27
ECPM1 medium, 5.3.13
EDTA (ethylenediamine tetraacetic acid), 0.5 M (pH 8.0),A.2E.1
EDTA, 200 mM, 14.1.10
EDTA, 2%, 10.4.28
electrode solutions, 7.3.17
electrophoresis buffer
  pH 1.9, 13.3.6
  pH 3.5, 13.3.6–13.3.7
  for urea-gradient gels, 7.4.5
Ellman's reagent solution, 18.3.14
endo H digestion buffer, 12.3.7
enzyme solutions
  clostripain, 11.2.5
  endoproteinases, 11.2.4–11.2.5
  trypsin, 11.2.4
equilibration buffer, 10.4.28

Reagents and Solutions (continued)

ethanolamine hydrochloride, 9.6.12
ethidium bromide, 10 mg/ml, A.2E.1
N-ethylmaleimide (NEM), 14.1.11
extracellular buffer, 13.8.16
extraction buffer, 6.3.7
extraction solution (40% acetonitrile/1% trifluoroaceticacid), 10.7.11
Farmers reducer, 10.5.10
fast-evaporation MALDI solution, 11.6.10
FBS (fetal bovine serum), A.3C.11–A.3C.12
formaldehyde fixing solution, 10.5.10
formamide loading buffer, 9.6.12
gel-filtration buffer, 6.2.10, 6.3.7
gel-filtration chromatography
  buffers, 8.3.22–8.3.23
  calibration standards, 8.3.23, 8.3.24 (table)
  columns, for separating released oligosaccharides, 12.4.12
  total liquid volume marker, 8.3.23
  void marker, 8.3.23
glass beads, acid washed, 5.8.11
L-glutamine, 0.2 M, A.3C.12
glutaraldehyde solution, 18.3.14
glutathione
  buffer, 6.6.17
  stock solutions, 0.1 M, 6.5.16
glycine buffer, for immunoaffinity chromatography, 9.5.8
glycine gel buffer, 4×, 10.3.8
GPI-PLD buffer, 12.5.9
guanidine·HCl, 18.3.14
GuMCAC buffers, 9.4.11
GuMCAC-EDTA buffer, 9.4.11
Hanks' balanced salt solution (HBSS), A.3C.12
Hartree-Lowry reagents, 3.4.14
HCDF1 medium, 5.3.13
HCDM1 medium, 5.3.14
HCl, 1 M, A.2E.2
HEPES, 14.1.10
holmium oxide reference solution, 7.2.13
homogenization buffer, 4.3.10, 5.10.28
homogenization medium (lectin adsorption), 4.2.44
homogenization medium (velocity differential centrifugation) 4.2.44
horseradish peroxidase, A.2A.24
HPLC solvents, 7.3.17
HRPO substrate solution, 4.3.11
hydrazine detection reagent, A.2A.24
hydroxylamine·HCl (pH 7.5), 1 M, 12.5.10
hydroxylamine solution, 11.4.5, 11.5.7
hyperosmotic buffer, 4.2.44
hyperosmotic homogenization medium (colloidal gold density shift), 4.2.43
IEF solubilization buffer, 10.2.6
IMC medium, 6.7.9
IMC plates, 6.7.9
immunoprecipitate wash buffer for boiled sample, 13.2.5
immunoprecipitation wash buffer for analysis of disulfidebond formation, 14.1.11
indole-3-acrylic acid, 5.2.13
inducer stock solutions, 5.2.13
inhibitor stock solutions, 12.3.7
interleukin
  break buffers, 6.5.16
  extraction buffer, 6.5.18
  folding buffer, 6.5.18
internalization medium, 4.3.11
intracellular buffer, 13.8.16
isopropyl-β-thiogalactopyranoside, 5.2.13
isopropyl-1-thio-β-D-galactopyranoside (IPTG), 6.6.17
KCl, 1 M, A.2E.2
LB medium, 5.2.13

Reagents and Solutions (continued)

leupeptin, 10.4.28
linker-kinase buffer, 9.6.12
loading buffer, 10×, 9.7.10
luminescent visualization solutions, 10.10.8
lyophilization buffer (25 mM sodium phosphate, pH 7.5/0.5mM sodium azide), 6.2.10
lysis buffer
  for analysis of disulfide bond formation, 14.1.11
  for extraction of insoluble *E. coli* proteins, 6.3.7
  for immunoaffinity purification, 9.5.8
lysis buffer
  for immunoprecipitation, 13.8.16
  for inhibition of N-linked glycosylation, 12.3.7
  for kinase assays, 13.7.18
  for preparation of soluble *E. coli* proteins, 6.2.10
  for preparing soluble GST fusion protein, 6.6.18
  two-dimensional gel electrophoresis, 10.4.28
M9 salts, 6.7.10
Mg/ATP solution, 13.7.19
MALDI matrix solution, 11.6.10
mass standard solution, 11.6.11
MCAC buffers, 9.4.12
MCAC-EDTA buffer, 9.4.12
methionine, 14.1.11
mevalonic acid, 100 mM, 14.3.7
mevinolin, 10 mM, 14.3.7–14.3.8
7.4 M medium, 4.3.10
M9 medium, 9.4.11
$MgCl_2$, 1 M, A.2E.2
$MgSO_4$, 1 M, A.2E.2
mild lysis buffer, 13.2.5
M9 minimal medium, 5.2.13
modification mixture, 11.9.28
multiply deficient medium, 12.2.8–12.2.9
M9ZB medium, 9.4.11
NaCl, 5 M, A.2E.2, A.2E.3 (table)
NaOH, 10 M, A.2E.2
NED solution, 11.7.11
ninhydrin, 3.4.15
nutrient supplements for YNB medium, 5.8.13 (table)
orthophosphoric acid (H_3PO_4), 10.4.28
oxidizer, 10× and 1×, 10.5.10
PBS, 10.4.28
PBS/BSA, 13.8.16
PBS/EDTA, 6.6.18
PBS/EDTA/PMSF buffer, 6.6.18
PBS/glycerol buffer, 6.6.18
PBS with proteolysis inhibitors, 10.4.29
pepstatin, 10.4.29
Percoll gradient stock solutions, 4.2.44
permeabilization buffer, 13.8.17
PGA digestion buffer, 11.7.11
PGA-N substrate, 11.7.2
phenol, buffered, A.2E.2
phosphate buffer, A.2A.24
phosphate-buffered saline (PBS), 13.2.5, A.2E.3
phosphate gel buffer, 4×, 10.3.8
phosphate/SDS, pH 7.2, 10.1.13
phosphate/SDS sample buffer, 2×, 10.1.29
phosphoamino acid standards mixture, 13.3.7
physiological buffer, pH 7.4, 3.6.11
piperidine/DMF, 18.2.15
PI-PLC buffer (for *B. thuringiensis* enzyme), 12.5.10
PKC reaction buffer, 13.7.19
plates, 5.2.14
plug solution, 10.1.28
PMSF, 14.1.12

BOSTON UNIVERSITY MEDICAL CENTER LIBRARY

- polyacrylamide gels
  - acetic acid nondenaturing, 10.3.2 (table)
  - acrylamide/bisacrylamide
  - 30%/0.8%, 10.1.5
  - 30%/1.6%, 10.2.6
  - glycine nondenaturing, 10.3.5 (table)
  - heavy acrylamide solutions, for gradient gels, 10.1.19, 10.1.23
  - light acrylamide solutions, for gradient gels, 10.1.19, 10.1.22
  - modified Laemmli peptide separating and stacking gels, 10.1.12
  - multiple single-concentration, 10.1.16
  - phosphate nondenaturing, 10.3.3
  - separating and stacking, 10.1.5
  - tricine peptide separation and stacking gels, 10.1.10
  - Tris nondenaturing, 10.3.4 (table)
- polyacrylmide-urea gel, 16%, 9.6.13
- potassium acetate buffer, 0.1 M, A.2E.3
- potassium phosphate buffer, 0.1 M, A.2E.4
- protease inhibitor cocktail
  - for MCAC, 9.4.12
  - for subcellular fractionation, 4.3.11
  - for yeast, 5.8.12
- protease inhibitor mix, 5.5.13
- protease inhibitor stock solutions, for kinase assays, 13.7.19
- proteinase inhibitor cocktail, 4.2.44
- protein extraction buffer, 5.8.12
- PTM_1 salt solution, 5.8.12
- radioactive ink, 14.3.8
- rate zonal centrifugation gradient stock solutions, 4.2.45
- reducing buffer, 10.4.29
- reduction/acylation cocktail, 15.1.15
- resuspension buffer, 5.10.28
- RIPA (RadioImmunoProtection Assay) correction buffer, 13.2.5
- RIPA (RadioImmunoProtection Assay) lysis buffer, 13.2.5–13.2.6
- RP-HPLC solvents, 6.5.18
- RPMI, complete, A.3C.11
- running buffer, 4.2.45
- sample buffer, nonreducing, 14.1.12
- SDS
  - 10%, 10.1.12
  - electrophoresis buffer, 5×, 10.1.27–10.1.28
  - lysis buffer, 13.2.6
  - recrystallized, 10.1.28
  - sample buffer
  - 2×, 10.1.28
  - 6×, 10.1.29
- SDS, 20%, A.2E.4
- SDS-PAGE sample buffer, 6.7.10, 13.8.17
- side chain deprotecting solution, 18.2.16
- small peptide mixture, 14.1.12
- SOC medium, 5.2.14N2 = sodium acetate, 3 M, A.2E.4
- sodium acetate buffer, 0.1 M, A.2E.4
- sodium phosphate buffer, 9.5.8
- sodium phosphate buffer, 0.1 M, A.2E.4
- sodium sulfite reagent buffer, 15.1.15
- sonication buffer, 18.2.16
- SSC (sodium chloride/sodium citrate) 20×, A.2E.4
- standard protein solution, 3 mg/ml, 3.1.3
- stop buffer, 14.1.12
- streptolysin O solutions, 13.8.17
- sucrose solutions, 4.3.11–4.3.12
- sulfanilic acid solution, A.2A.24
- synthetic peptide substrate solution, 13.7.19
- TAE (Tris/acetate/EDTA) electrophoresis buffer, A.2E.4
- TBE electrophoresis buffer, pH 8.1, A.2A.25
- TBE (tris/borate/EDTA) electrophoresis buffer, 9.6.13,A.2E.4
- TBS, 12.5.10
- TE buffer, A.2E.4
- T4 polynucleotide kinase buffer, 9.6.13
- thiosulfate developing solution, 10.5.10
- thrombin, 2000 NIH units/ml, 6.5.18
- trace element solutions 1 & 2, 5.3.14
- transfer buffer, 10.6.6
  - 20×, 10.7.11
- tricine sample buffer, 2×, 10.1.29
- triethanolamine solution, 9.5.8
- Tris-buffered saline (TBS)
  - for immunoblot detection), 10.10.9
  - for phosphoamino acid analysis, 13.3.7
- Tris·Cl
  - pH 6.8, 4×, 10.1.12
  - pH 8.8, 8×, 10.1.12
- Tris·Cl/SDS
  - pH 6.8, 4×, 10.1.5
  - pH 8.45, 10.1.10
  - pH 8.8, 4×, 10.1.5
- Tris-buffered saline (TBS), 13.2.6
- Tris gel buffer, 4×, 10.3.9
- Tris/glycerol solubilization buffer, 2×, 10.3.9
- Tris/glycine electrophoresis buffer, 10.3.9
- Tris/guanidine buffer, 15.1.16
- Tris/saline/azide (TSA) solution, 9.5.9, 12.3.7
- Tris/SDS buffer, 10.4.29
- Tris/Triton/NaCl buffer, 9.5.9
- Triton/SDS buffer, 10.7.11
- Triton X–100 solution, 20%, 10.4.29
- trypsin/EDTA solution, A.3C.12
- tryptophan, 6.7.10
- Tween 20/TBS (TTBS), 10.10.9
- two-dimensional-PAGE
  - lysis buffer, 13.8.17
  - sample buffer, 13.8.17
- tyrosine kinase reaction buffer, 13.7.20
- U buffer, 6.6.18–6.6.19
- urea/acrylamide gel solutions, 7.4.5
- urea, 8 M, 10.4.29
- vitamin solution, 5.8.12
- wash buffer
  - for analysis of disulfide bond formation, 14.1.12
  - for exclusion-body extraction, 6.3.7
  - for immunoaffinity chromatography, 9.5.9
  - for preparing soluble GST fusion protein, 6.6.19
- water-saturated *n*-butanol, 12.5.10
- YNB stock, 5.8.12
- YNB medium, 5.8.13
- YP broth, 5.8.13

Receptor agonists, permeabilization strategies, 13.8.18

Receptor-mediated signal transduction, 17.1.9–17.1.10

Receptors, mammalian expression of, 5.9.10

Recombinant proteins
- characterization
  - chemical identity, 7.1.2–7.1.3
  - contaminants, 7.1.1–7.1.2
  - N-terminal heterogeneity in *E. coli*, 7.1.9–7.1.11
  - physical and conformational, 7.1.3–7.1.9
  - strategy, 7.1.9

silver, colloidal, 10.8.4
staining sensitivities and membrane compatabilities, 10.8.1
negative, preparative technique for electronmicroscopy, 17.2.14 (fig.), 17.2.16, 17.2.17 (fig.)
of polyacrylamide gels
in continuous nondenaturing electrophoresis, 10.3.3
Coomassie blue staining, 10.5.1–10.5.3, 10.5.11
in denaturing discontinuous gel electrophoresis, 10.1.7
in IEF, 10.2.7
photography, 10.5.8–10.5.9
in SDS-PAGE, 10.1.32
silver staining, 10.5.4–10.5.8, 10.5.11
in quantitation for N-terminal sequencing, 11.10.11
Staphylococcus aureus, in immunoprecipitation of proteins, 14.1.7–14.1.8
STEM, *see* Scanning transmission electron microscopy*and* Electron microscopy
Step gradients
in gradient fractionation using deuterium oxide, 4.2.19
in gradient fractionation using nonionic iodinated solutes, 4.2.21–4.2.22
in hydroxylapatite chromatography, 8.6.6–8.6.7
Steric exclusion chromatography, *see* gel-filtration chromatography
Sterile technique, in tissue culture, A.3C.1–A.3C.4
Streptavidin, purification of DNA-binding proteins,UNIT 9.7
STL, in glycoprotein purification, 9.1.2 (table)
Stochastic random sequence model, 12.1.10
Stoichiometric iodination, 3.3.7, 3.3.9
Stoichiometry, assessment by electron microscopy, 17.2.3
Stokes radius, 7.8.10, 8.3.25
Storage
of hazardous chemicals, A.2A.2–A.2A.3
of recombinant proteins, 6.1.16, 6.2.9, 6.2.14
of recombinant strains, 5.2.8–5.2.9
Storage granules, density gradient centrifugation in nonionic solutes, 4.2.47
STREAMLINE media, 8.2.5 (table)
Streptolysin O, for permeabilization, 13.8.2–13.8.4, 13.8.8, 13.8.18
Streptomycin, in nucleic acid removal, 1.3.1
Stringent control in plasmid replication, 5.1.1
Structural assays, of protein purity, 8.1.2

Structural proteins
classification, 1.2.2 (table)
functional assessment, 8.1.2–8.1.3
translocation in mammalian cells, 5.9.9, 5.9.10
Structure
immunoglobulins, 17.1.4–17.1.5
MHC peptide-binding fold, 17.1.5
primary, 17.1.1
of proteins
analysis by electron microscopy, UNIT 17.2
calcium-binding proteins, 17.1.25–17.1.26
in classification, 1.2.1
in cytoskeleton and muscle movements, 17.1.32–17.1.33
DNA-binding, 17.1.13–17.1.20
electron-transfer, 17.1.38–17.1.39
enzymes, 17.1.29–17.1.32, 17.1.33–17.1.38
globin-like, 17.1.39–17.1.40
large multisubunit, 17.1.41–17.1.44
lectins, 17.1.24–17.1.25
mammalian expression of proteins and variations in, 5.9.12
membrane, 17.1.44–17.1.45
nucleotide-binding, 17.1.26–17.1.29
purification methods based on, 1.1.4
recombinant, 7.1.2–7.1.3, 7.1.7–7.1.8
RNA-binding, 17.1.20–17.1.24
signal-transduction pathway proteins, 17.1.5–17.1.13
toxins, 17.1.40–17.1.41
X-ray crystallography of, UNIT 17.3
quarternary, 17.1.2
secondary
elements of, 17.1.1
hydropathy profile correlation, 2.2.7–2.2.8, 2.2.9 (fig.) 2.2.10
prediction from sequence
Chou and Fasman method, 2.3.4–2.3.5, 2.3.6 (fig.), 2.3.8, 2.3.9 (fig.), 2.3.10 (fig.)
compact domains, 2.3.1
comparison of schemes, 2.3.11–2.3.18
EMBL Profile Neural Network method, 2.3.2–2.3.3, 2.3.8
Garnier, Osguthorpe, and Robson method, 2.3.5–2.3.7, 2.3.8
groups of proteins involved, 2.3.1
Guzzo and Prothero method, 2.3.1
helical net, 2.3.2
helical wheel method, 2.3.1–2.3.2, 2.3.7–2.3.8
hydrophobic residues, 2.3.1
Lim's method, 2.3.2
polar residues, 2.3.1
Protein Sequence Analysis method, 2.3.7, 2.3.8–2.3.9
software, 2.3.18
statistical method, 2.3.2
strategy, 2.3.3
tertiary, 17.1.2
three-dimensional
assemblies/motifs commonly observed, 17.1.2–17.1.3
database access through Internet, 17.1.3–17.1.4
database searching, 2.3.2–2.3.3
elements of, 17.1.2
fold analysis, 17.1.3
Structure factor, in X-ray crystallography, 17.3.1–17.3.2, 17.3.5
Stultz method of secondary structure prediction, 2.3.3
Subcellular fractionation of tissue culture cells
analysis of fractions, 4.3.13–4.3.16, 4.3.18–4.3.19
balance sheet, 4.3.15
density-shift methods, 4.3.13
endosomal compartment labeling conditions, 4.3.2 (table)
flotation-gradient fractionation of homogenates, 4.3.8–4.3.9
free-flow electrophoresis, 4.3.13
gradients, 4.3.12–4.3.13
growth and experimental conditions of cells, 4.3.17
homogenization of cells, 4.3.6–4.3.7, 4.3.16–4.3.18
HRPO activity determination, 4.3.7
immunoisolation of endosomal fractions, 4.3.9–4.3.10, 4.3.13–4.3.14
internalization of fluid-phase marker, 4.3.1–4.3.3
preparation of cells for, 4.3.10
strategy, 4.3.12
VSV G protein implantation and internalization, 4.3.3–4.3.5
Subcellular fractions
direct analysis of cytosolic or membrane-bound kinases, 13.8.10
permeabilization for phosphorylation studies, 13.8.7–13.8.9
Substitution in sequence analysis, 2.1.1
Subtilisin
compatibility with other proteases, 11.1.13–11.1.16
conditions for activity, 11.1.2 (table)
proteolysis of undenatured substrates, 11.1.6 (table)
specificity of digestion, 11.1.12 (table)
SUC2 gene, 5.6.4 (fig.), 5.6.5 (table)
Succinic anhydride
as blocking reagent, 11.7.5–11.7.8
in modification of amino groups, 15.2.8–15.2.11,
Succinimidyl esters, in modification of amino groups
amidation using, 15.2.5–15.2.7
vs. sulfosuccinimidyl esters, 15.2.6 (fig.)
Succinimidyl 4-(*N*-maleimidomethyl)-cyclohexane-1-carboxylate (SMCC), for coupling synthetic peptides to carrier proteins, 18.3.8
Succinylation, modification of amino groups by, 15.2.8–15.2.11
Sucrose
in organelle purification
centrifugation media, 4.1.5–4.1.7
density shift using colloidal gold conjugates, 4.2.41–4.2.42
density shift using digitonin, 4.2.35–4.2.37, 4.2.38 (fig.)
gradient in differential centrifugation by equilibrium, 4.2.9–4.2.11
rate zonal centrifugation, 4.2.2, 4.2.12–4.2.14, 4.2.15 (fig.)
refractive index, 4.2.17
in storage of recombinant proteins, 6.1.16
in subcellular fractionation, 4.3.13 (table)
Sugar, reducing, defined, 12.1.7
Sugar alcohols, as centrifugation media, 4.1.5
Sugars
calibration plots for spectrophotometric assays, 3.4.16, 3.4.17 (table)
as interfering compound in BCA assay, 3.4.19
in lectin affinity chromatography, 9.1.1–9.1.4, 9.1.8–9.1.9
See also Glycoconjugate analysis
Sulfhydryl groups
assay using Ellman's reagent, 18.3.9–18.3.11
colorimetric quantitation of, 15.1.13
molar extinction coefficients of when reacted with Ellmanreagent, 15.1.13 (table)
Sulfhydryl reagents, as interfering compound in BCA assay, 3.4.19
Sulfitolysis, modification of cysteine residues by, 15.1.9
Sulfo-NHS-biotin, 3.6.2 (table), 3.6.4–3.6.6, 3.6.11
Sulfonyl chlorides, in activating matrix hydroxyl function, 9.3.2 (table)
Sulfuric acid, in acid digestion–ninhydrin assay, 3.4.7–3.4.8
Superantigen toxins, 17.1.41
Superdex resins
74, 6.2.8
75, 6.3.11 (fig.), 6.3.14 (fig.)
200, 6.3.11 (fig.), 6.3.13–6.3.14
columns, 8.3.5 (table), 8.3.17 (fig.)
in gel-filtration chromatography, 6.3.10–6.3.11
matrices, 8.3.4 (table)
Superose
columns, 8.3.5 (table)
matrices, 8.3.4 (table), 8.4.2 (table)
Superoxide dismutase
endoproteinase digestion of, 11.1.6 (table)
protease digestion of, 11.1.15 (fig.)
Surface features, purification methods based on, 1.1.3–1.1.4
Suspension cells
HRPO internalization, 4.3.1–4.3.3
recombinant protein production in mammalian cells, 5.10.1–5.10.2, 5.10.12–5.10.14, 5.10.31
Suspension cultures, permeabilization, 13.8.4–13.8.5, 13.8.6, 13.8.7
Svedberg equation, 4.1.2
Svedberg unit, 7.5.2
Swainsonine
concentrations for dilution series, 12.3.4 (table)
oligosaccharide structure, effects on, 12.3.2 (table), 12.3.8
SWISS-PROT database, 2.1.5
Switch-valve-based gradient mixing, 8.2.22–8.2.23
Synaptic vesicles
in electrophoresis, 4.2.47
fractionation, 4.1.8 (table)
gel filtration, 4.2.47
Synchrotrons, 17.3.2
Synthesis of peptides, labeling
of amino acids during, 3.3.14–3.3.15
on N-terminus during, 3.3.15

T

tac promoter
induction in *E. coli*, 5.2.4, 5.2.14–5.2.15

Tricine, in peptide electrophoresis, 10.1.9–10.1.13, 10.1.31
Triethanolamine/acetic acid, in homogenization medium, 4.3.17
Trifluoroacetic acid (TFA)
  in recombinant protein purification, 6.1.14
  in removal of acetyl blocking groups, 11.7.10
Triosephosphate isomerase
  endoproteinase digestion of, 11.1.6 (table)
  protease digestion of, 11.1.15 (fig.)
Tripos/Biopolymer (software), 2.3.11 (table)
Tris-based buffers
  nondenaturing polyacrylamide gels, 10.3.3 (table)
  in recombinant protein purification, 6.1.14
  Tris/borate in electroblotting, 10.7.13
  urea and, 11.10.8
N,N,N'-Tris (carboxymethyl)ethylenediamine, 9.4.13
Trisose phosphate isomerase, 17.1.35
Tris-tricine in electrophoresis, 10.1.9–10.1.13, 10.1.31 11.4.2, 11.4.3, 11.4.4, 11.4.5, 11.4.7, 11.4.8, 11.5.7
Triton/SDS solution, 10.7.9
Triton X-100
  in enzymatic digestion on PVDF membranes, UNIT 11.2
  in extraction of inclusion bodies from recombinant expression systems, 6.3.2
  in glycoprotein denaturation, 12.4.14
  in IEF, 10.4.29, 10.4.31, 10.4.33, 10.4.35
Triton X-114
  in extraction and partitioning of GPI-containing proteins, 12.5.3–12.5.4, 12.5.11, 12.5.12
  precondensation, 12.5.4
trxA gene, 6.7.1–6.7.5
T7 RNA polymerase promoter
  induction in *E. coli*, 5.2.5, 5.2.15
  summary of system, 5.1.2, 5.2.2 (table)
  transformation of *E. coli* cells, 5.2.5
Trp, *see* Tryptophan
trp promoter
  chemical induction, 5.2.3–5.2.4, 5.2.15
  in fermentation, 5.3.6
  summary of system, 5.2.2 (table)
Trypan blue exclusion method in baculovirus expression system 5.5.12–5.5.13
Trypan blue staining, A.3C.8–A.3C.10
Trypsin
  in cleavage of proteins
    avoiding chemical modification of proteins for, 11.10.8
    in gels, 11.3.1, 11.3.7–11.3.8
    on membranes, 11.2.2 (table), 11.2.4, 11.2.9 (fig.)
    for N-terminal sequencing, 11.10.2, 11.10.34
    sequence analysis of, 11.1.17 (table)
    in solution, 11.1.2 (table), 11.1.6 (table), 11.1.13–11.1.15
  in electrophoresis, 4.2.28
  specificity of digestion, 11.1.12 (table)
Trypsin inhibitor, endoproteinase digestion of, 11.1.6 (table)
Tryptic peptide masses, 11.10.34–11.10.35
Tryptophan (Trp)
  as chromophore in fluorescence, 7.7.1, 7.7.11–7.7.13
  cleavage at C-terminus with BNPS-skatole
    on membranes, 11.5.4–11.5.5
    in solution, 11.4.2–11.4.3, 11.4.5, 11.4.7 (table)
  contribution to circular dichroism spectra, 7.6.1.7.6.16–7.6.18
  in model protein construction, 7.1.7–7.1.8
  in protein detection in polyacrylamide gels, 10.6.7
  quantitation of, in amino acid analysis, 11.9.25–11.9.26
  in recombinant protein labeling, 6.1.18
  in spectrophotometric determination of protein concentration
    absorbance, 3.1.1–3.1.2, 3.1.4–3.1.6
    fluorescence emission, 3.1.3, 3.1.4–3.1.5
  in thioredoxin expression system, 6.7.2–6.7.3
  transitions of, electronic, 7.6.1, 7.6.16 (table)
  UV absorption spectroscopy of, UNIT 7.2, 3.4.9–3.4.10, 3.4.20
Tryptophan operon, *see trp* promoter
TSK columns, 8.3.5 (table)
TSK matrices, 8.4.2 (table)
Turbidimetry, 7.8.1, 7.8.3
Tubing, dialysis, 6.2.7
Tunicamycin
  concentrations for dilution series, 12.3.4 (table)
  oligosaccharide structure, effects on, 12.3.2 (table), 12.3.8
TurboGopher
  defined, 2.4.12
  Home Gopher window, 2.4.12–2.4.13 (figs.)
Tween 20, cleavage in gels containing, 11.3.1–11.3.4, 11.3.8
Two-dimensional electrophoresis
  IEF in, 10.2.7
  of phosphoamino acids, 13.3.1–13.3.5, 13.3.7–13.3.8
Tyrosine
  as chromophore in fluorescence, 7.7.1, 7.7.11–7.7.13
  contribution to circular dichroism spectra, 7.6.1, 7.6.16 (table)
  iodination
    equimolar, 3.3.7
    product separation by HPLC, 3.3.8–3.3.9
    reaction, 3.3.2 (fig.)
    using chloramine T or iodogen, 3.3.5–3.3.6
    using Iodo-Beads, 3.3.3–3.3.5
    using lactoperoxidase, 3.3.6–3.3.7
  labeling strategies, 3.3.1 (table)
  in model protein construction, 7.1.7–7.1.8
  in spectrophotometric determination of protein concentration
    absorbance, 3.1.1–3.1.2, 3.1.4–3.1.6
    fluorescence emission, 3.1.3, 3.1.4–3.1.5
  transitions of, electronic, 7.6.1, 7.6.3 (fig.), 7.6.16, 7.6.17 (fig.)
  UV absorption spectroscopy of, UNIT 7.2, 3.4.7 (fig.), 3.4.9–3.4.10, 3.4.20
Two-dimensional gel electrophoresis
  diagonal, 10.4.25–10.4.26, 10.4.33
  formats, 10.4.1
  IEF
    high-resolution equilibrium in tube gels, 10.4.2–10.4.7
    immobilized pH gradient gels, 10.4.13–10.4.16, 10.4.32–10.4.34
    immobilized pH gradient gel strips, 10.4.9–10.4.13
    investigator 2D gel system, 10.4.33
    molecular weight standards preparation, 10.4.24
    nonequilibrium of very acidic proteins, 10.4.8, 10.4.32
    nonequilibrium of basic proteins, 10.4.8–10.4.9, 10.4.32
    pH profile measurements, 10.4.7
    using soluble ampholytes, 10.4.31–10.4.32
    tissue culture cell extracts, 10.4.17–10.4.19
    tissue sample preparation, 10.4.19
    tube gels, 10.4.20–10.4.22
  IPG gels, 10.4.22–10.4.23
  protein databases, 10.4.26–10.4.27
  size options, 10.4.31 (table)
Tyrosine kinases
  assay for, 13.7.11–13.7.8
  in recombinant expression systems, infolding, 6.1.15
Tyrosine phosphatases, in phosphoprotein digestion, 13.5.4, 13.5.6
Tyrosine-phosphorylated peptides, *see* Peptides, tyrosine-phosphorylated
Tyrosine protein kinase, post-translational modifications in insect cells, 5.4.3
Tyrosines, detection
  acid hydrolysis and two-dimensional electrophoresis, 13.3.1–13.3.5
  alkaline hydrolysis of blotted proteins, 13.3.6

BOSTON UNIVERSITY / CENTRAL LIBRARY

alkaline phosphatases in, 13.5.3–13.5.4
immunological techniques, 13.1.2, UNIT 13.4

U

Ubiquitin, 6.1.3
Udy dye–binding assay, 3.4.21
UEA-I, in glycoprotein purification, 9.1.3 (table)
Ultracentrifugation
analytical, UNIT 7.5
for X-ray crystallography samples, 17.3.9–17.3.11
of recombinant proteins, 7.1.4 (table)
Ultrafiltration
applications, 4.4.1
centrifugal, for concentration or desalting, 4.4.8–4.4.9
concentration polarization, 4.4.11
membrane selection and characteristics, 4.4.4–4.4.5, 4.4.6, 4.4.9–4.4.13
precipitation of protein, 4.4.12
of recombinant protein expression systems, interleukin1β, 6.2.8
in recombinant soluble protein purification, 1.3.1
rejection of solute, 4.4.11
tangential-flow, for diafiltration or concentration, 4.4.6–4.4.8
through asymmetric membrane disks, for concentration ordialysis, 4.4.4–4.4.6, 4.4.12 (table)
volume of filtrate for, 4.4.11
Ultrathin gels, casting and running, 10.1.14–10.1.15
Ultraviolet absorption spectroscopy in
in capillary electrophoresis, 10.9.2–10.9.3, 10.9.11
in protein concentration determination 3.1.1–3.1.2, 3.1.4–3.1.6
of recombinant proteins
absorption flattening, 7.2.16
applications, 7.2.1–7.2.2
conventional scanning instruments, 7.2.14–7.2.15
using far-UV absorption spectra, 7.2.14
HPLC with diode-array detector, 7.2.10–7.2.12, 7.2.14–7.2.17, 7.2.18 (fig.), 7.2.19 (fig.)
intepreting near-UV spectra, 7.2.5–7.2.10
using near-UV absorption spectra, 7.2.2–7.2.5, 7.2.13–7.2.14, 7.2.16
pH in, 7.2.15
photooxidation of tryptophan, 7.2.15
temperature in, 7.2.14–7.2.15
in recombinant protein characterization, 7.1.6 (table)
in total protein quantitation
absorption spectra, 3.4.19 (fig.), 3.4.20
interfering compounds, 3.4.18 (table)
method, 3.4.10
molar absorption coefficients, 3.4.9–3.4.10
Ultraviolet lamps, 7.2.2, 7.2.15 (fig.), 7.2.16
Ultraviolet light wavelengths, 10.12.5
Ultrogel AcA54, 6.2.6, 6.2.6 (fig.), 6.2.8
Undecagold, for labeling in electron microscopy, 17.2.21
Unfolding of proteins
curve, 7.4.9 (fig.)
free energy change for, 7.4.6, 7.4.10
kinetics of, 7.4.6, 7.4.9–7.4.12
study via titration curve analysis, 7.3.13–7.3.15
See also Folding of proteins
Uniform resource locator (URL), 2.4.13–2.4.14
Unweighted Pair-Group Method using Arithmetic Averages (UPGMA), 10.12.12 (fig.)
URA3 gene, 5.6.3
Urea
in aggregation, 6.4.6
avoiding protein modification by, 11.10.8
concentration and reversible unfolding transition, 6.4.4
in cysteine modification, 15.1.2–15.1.3
in enzymatic digestion of proteins in gels, 11.3.5
in glycoprotein denaturation, 12.4.14
in solution, 11.1.2 (table), 11.1.4–11.1.5, 11.1.13–11.1.16
in folding, 6.5.3
in IEF, 10.4.4, 10.4.17, 10.4.33
recombinant proteins and
bovine growth hormone extraction and purification, 6.5.19, 6.5.20
inclusion body extraction, 6.1.12 (fig.), 6.1.13–6.1.14 6.3.2
soluble proteins, 6.1.5–6.1.6
Urea-gradient gel electrophoresis
advantages of, 7.4.7
calculations from, 7.4.9–7.4.11, 7.4.10 (fig.)
method, 7.4.1–7.4.5
patterns produced by proteins, 7.4.11 (fig.), 7.4.12 (fig.)
preparation of gel for, 7.4.1 (fig.), 7.4.3 (fig.)
of recombinant proteins, 7.1.4 (table), 7.1.7
unfolding curve produced by, 7.4.9 (fig.)
Uridine monophosphate, two-dimensional electrophoresis, 13.3.7

V

Vacuum aspiration, drawbacks in radiolabeling, 13.2.7
Van't Hoff enthalpy, 7.9.11–7.9.12
Variant surface glycoprotein (VSG), 12.5.10
Vectastain ABC kit (Vector), use in immunoprobing, 10.10.3–10.10.4

Current Protocols in Protein Science

Supplement 14 **New and Revised Topics** **December 1998**

In this Supplement ...

☑ Sample Preparation for MALDI *(New)* UNIT 16.3

☑ MALDI-MS Fingerprint Mapping *(New)* UNIT 16.4

☑ Protein Identification Using MS-Fit and MS-Tag *(New)* UNITS 16.5 & 16.6

☑ Protein-Protein Interactions *(New)* UNIT 19.1

☑ Interaction Trap/Two-Hybrid System *(New)* UNIT 19.2

Coming soon ...

☑ Peptidic Dendrimers as Protein Mimetics *(New)*

☑ Capillary Electrophoresis Using Isoelectric Buffers *(New)*

☑ BLAST *(Revised)*

This supplement includes important new topics to bring your CPPS subscription up to date with the latest methodology. Also included is a reader response card for forwarding us your comments and suggestions. Please see next page for a full listing of contents and instructions for inserting pages.

For more detailed information about new and upcoming topics, please visit the Current Protocols Home Page at *www.wiley.com/cp.*

Routing List

After filing, you may wish to route this cover sheet to other Current Protocols users to keep them informed of the new topics.

FULL CONTENTS OF SUPPLEMENT 14

Instructions for Adding Pages to Core Manual

Full contents for Supplement 14 are listed below, with instructions for removing old pages and inserting new pages. Every page included with Supplement 14 is labeled as such beneath the page number.

Remove pages	Insert pages	Subject	Primary change/notes
VOLUME 1			
Main TOC: 3-5	Main TOC: 3-5	Main table of contents	Reflects new material in Chap. 16, new Chap. 19, and App. 4
5.0.1-5.0.3	5.0.1-5.0.3	Chapter 5 introduction	Revision
5.9.3-5.9.4	5.9.3-5.9.4	Mammalian cell expression	Revision
5.15.1-5.15.2	5.15.1-5.15.2	Vaccinia virus/T7 RNA polymerase hybrid system	Revision
7.7.15-7.7.16	7.7.15-7.7.16	Fluorescence spectrum	Revision
Ch 8:1-2	Ch 8:1-2	Chapter 8 contents	Reflects *UNIT 8.3* revisions
8.3.1-8.3.30	8.3.1-8.3.30	Gel-filtration chromatography	Revised *UNIT 8.3*
10.1.3-10.1.4	10.1.3-10.1.4	SDS-PAGE	Revision
VOLUME 2			
Vol. 2 contents (2 pages)	Vol. 2 contents (2 pages)	Core contents	Reflects new Chap. 19
Ch 16:1	Ch 16:1	Chapter 16 contents	Reflects new *UNITS 16.3-16.6*
—	16.3.1-16.3.6	Sample preparation for MALDI	New *UNIT 16.3*
—	16.4.1-16.4.5	In-gel digestion for MALDI-MS	New *UNIT 16.4*
—	16.5.1-16.5.6	MS-Fit	New *UNIT 16.5*
—	16.6.1-16.6.7	MS-Tag	New *UNIT 16.6*
Ch 18:1	Ch 18:1	Chapter 18 contents	Reflects new *UNITS 8.3*
—	New Chapter 19 and tab (48 pages)	Detection of protein interactions	New Chapter 19
Appendices:1-3	Appendices:1-3	Appendices contents	Reflects new *APPENDICES 1B, 1C, & 4L*
—	A.4L.1-A.4L.6	Growth and manipulation of yeast	New *APPENDIX 4L*
Supplement index (2 pages)	Supplement index (4 pages)	New supplement index	Entries covering Supplements 13 & 14

BCU IAS / CENTRAL UNIVERSITY LIBRARY

8 Conventional Chromatographic Separations

8.1 Overview of Conventional Chromatography
8.2 Ion-Exchange Chromatography
8.3 Gel-Filtration Chromatography
8.4 Hydrophobic-Interaction Chromatography
8.5 Chromatofocusing
8.6 Hydroxylapatite Chromatography

9 Affinity Purification

9.1 Lectin Affinity Chromatography
9.2 Dye Affinity Chromatography
9.3 Affinity Purification of Natural Ligands
9.4 Metal-Chelate Affinity Chromatography
9.5 Immunoaffinity Chromatography
9.6 Purification of Sequence-Specific DNA-Binding Proteins by Affinity Chromatography
9.7 Purification of DNA-Binding Proteins Using Biotin/Streptavidin Affinity Systems

10 Electrophoresis

10.1 One-Dimensional SDS Gel Electrophoresis of Proteins
10.2 One-Dimensional Isoelectric Focusing of Proteins in Slab Gels
10.3 One-Dimensional Electrophoresis Using Nondenaturing Conditions
10.4 Two-Dimensional Gel Electrophoresis
10.5 Protein Detection in Gels Using Fixation
10.6 Protein Detection in Gels Without Fixation
10.7 Electroblotting from Polyacrylamide Gels
10.8 Detection of Proteins on Blot Membranes
10.9 Capillary Electrophoresis of Proteins and Peptides
10.10 Immunoblot Detection
10.11 Autoradiography
10.12 Overview of Digital Electrophoresis Analysis

11 Chemical Analysis

11.1 Enzymatic Digestion of Proteins in Solution
11.2 Enzymatic Digestion of Proteins on PVDF Membranes
11.3 Digestion of Proteins in Gels for Sequence Analysis
11.4 Chemical Cleavage of Proteins in Solution
11.5 Chemical Cleavage of Proteins on Membranes
11.6 Reversed-Phase Isolation of Peptides

CHAPTER 5
Production of Recombinant Proteins

INTRODUCTION

This chapter deals with the production of recombinant proteins using the expression systems in common use. Methods describing the actual construction of the expression vectors or plasmids containing the genes coding the proteins of interest are described in detail elsewhere (Sambrook et al., 1989; Ausubel et al., 1997).

The most widely used and most important expression systems are those using *E. coli* as the host cell. An overview of the production of proteins in *E. coli* is provided in *UNIT 5.1*. General strategies for gene expression described include direct intracellular expression, secretion of the protein into the periplasmic space, and the expression of fusion proteins. Some of these strategies (e.g., secretion procedures) are used to overcome the common problem of inclusion body formation (see *UNIT 6.1* for additional discussion); others (e.g., fusions involving affinity tags) are used simply to assist in protein purification. Many of the expression vectors discussed are commercially available and suppliers are indicated throughout the text.

Protocols describing protein expression in transformed *E. coli* cells are provided in *UNITS 5.2 & 5.3*. First, protein expression in *E. coli* requires that a suitable host strain (tabulated in *UNIT 5.2*) be transformed with an expression vector. Electroporation, a quick and simple method for transforming *E. coli* host strains, is presented in *UNIT 5.2*. Second, the growth conditions and methods used to induce gene expression are optimized for the particular host strain and controllable transcriptional promoter used. Standard procedures for small-scale expression in shaker flasks using several of the most common expression vectors are also presented, along with protocols for determining plasmid stability and storing transformed strains at low temperature. Finally, methods for establishing the level of protein expression as well as solubility and location (intracellular or periplasmic) are described.

Once suitable host/vector combinations have been selected on the basis of the small-scale experiments described in *UNIT 5.2*, large-scale protein production can be carried out in fermentors with careful monitoring of cell growth. *UNIT 5.3* describes fermentation in batch mode using a fixed amount of medium. For higher-density fermentations, the fed-batch process is described: in this procedure the growth carbon source is continuously fed into the culture. Modifications to the standard fed-batch process are used to introduce the heavy atom derivative selenomethionine into recombinant proteins to facilitate X-ray structure determination and to uniformly label proteins with combinations of the stable isotopes ^{2}H, ^{13}C, and ^{15}N. Isotopically labeled proteins are required for high-resolution structural studies using nuclear magnetic resonance (NMR) spectroscopy (see *UNIT 7.1* for additional details). Protocols for growth monitoring and sterility checking are also included.

There are several eukaryotic cell–based expression systems available for overproducing recombinant proteins (consult Ausubel et al., 1997, Chapter 16), and most of these will eventually be covered in this chapter. One system, which uses insect cells infected with recombinant baculovirus, has become widely used. An overview of protein expression using the baculovirus system is given in *UNIT 5.4*. References covering the molecular

BOTANICAL CENTRE UNIVERSITY LIBRARY

biology required to construct the recombinant baculovirus vector that expresses the gene of interest are provided in the overview. Furthermore, references to protocols describing small-scale expression experiments are supplied in the introduction to *UNIT 5.5*.

The large-scale growth of insect cells infected with baculovirus is carried out in bioreactors, requiring large (liter) amounts of viral stock (*UNIT 5.5*). These stocks must have known titers and are analyzed in small-scale (1- to 3-liter) cultures in order to evaluate and optimize protein expression. For developing protein purification methods and for isolating moderate amounts of recombinant protein, small-scale cultures in shaker or spinner culture flasks may provide adequate starting material. Large-scale insect cell culture is carried out with more sophisticated equipment using bioreactors in either batch mode or perfusion mode. Cell harvesting is carried out by centrifugation or tangential-flow microfiltration. The cells (for intracellular expressed proteins) or the culture medium (for secreted proteins) are retained for downstream processing. Other protocols in this unit provide methods for preparing samples for SDS-PAGE to check protein expression levels and for monitoring nutrient levels in culture media.

Yeast is another important eukaryotic host used for protein expression. The molecular biology of *Saccharomyces cerevisiae* (baker's yeast) is described in Chapter 13 of Ausubel et al. (1997). An overview of protein expression in *S. cerevisiae* is given in *UNIT 5.6*, which details, as a case study, some of the machinations required to achieve high-level production of the human glycoprotein antithrombin 111 secreted into the extracellular medium.

Other strains of yeast apart from *S. cerevisiae* have also been used for heterologous protein expression, including the methylotropic yeast *Pichia pastoris*. There may be some advantages to using this host system over the more common *S. cerevisiae*, as expression levels, especially for intracellular proteins, can be higher. Protein expression using the *P. pastoris* system is reviewed in *UNIT 5.7*. The commonly used expression vectors are described, together with many examples of proteins successfully expressed with the system. Protocols describing the culture of the *S. cerevisiae* and *P. pastoris* strains with various expression vectors for heterologous protein expression are provided in *UNIT 5.8*.

An overview of protein expression using mammalian cells is presented in *UNIT 5.9*. The unit reviews the stages involved in protein production using the stable expression approach. As post-transcriptional modification and intracellular protein transportation are integral components of mammalian protein expression, descriptions of these mechanisms are included. Protocols for the production of recombinant proteins in mammalian cells using various culture configurations are described in *UNIT 5.10*. These are supplemented with a number of support protocols that include the first steps in downstream processing.

The transient expression of proteins in mammalian cells using a viral vector system is described in *UNITS 5.11-5.15*. Methods for constructing recombinant vaccinia virus are presented in *UNITS 5.11-5.13 & 5.15*. The characterization of the recombinant virus is described in *UNIT 5.14*. Proteins produced using this expression system are subject to normal mammalian post-translational processing.

The choice of protein expression system does depend on the intended use and characteristics of the protein. If a protein can be expressed in *E. coli* in a soluble state either directly into the cytoplasm or by secretion into the periplasm, then it may be possible to isolate large amounts of correctly folded and active protein (e.g., see *UNIT 6.2*). On the other hand, if the protein must be post-translationally modified (i.e., glycosylated or phosphorylated), a eukaryotic expression system must be used. Furthermore, if the protein is expressed in an insoluble state in *E. coli*, one way to circumvent this problem is to try expression in an eukaryotic system.

BCU IAS / CENTRAL UNIVERSITY LIBRARY

The baculovirus system complements *E. coli* expression systems and for many investigators is the system of choice, especially for expressing post-translationally modified proteins. Yeast has the advantage that it is cheap to grow (analogous to *E. coli*) but can produce hyperglycosylated proteins; moreover, occasionally protein produced at high levels is insoluble (again analogous to *E. coli*). If a glycoprotein is required for clinical studies, it must usually be produced by mammalian cell expression, as discussed in detail in *UNITS 5.9 & 5.10*. However, no expression system is without its drawbacks; some of the problems reported using the baculovirus and yeast systems are mentioned in *UNITS 5.4 & 5.6-5.8* and elsewhere (Bradley, 1990). In addition, a brief summary of the advantages and disadvantages of all the commonly used host systems is given in the booklet *The Recombinant Protein Handbook* (Pharmacia Biotech, 1994).

nied by death and rapid lysis of the cell. This presents the purification scientist with the challenge of fishing out the protein of interest, which may be present at ~5 µg/ml, from a soup of lysed cellular protein, nucleic acids, and viral particles. The yield of product during purification may be low as a result of the low titer and starting purity; however, when only small quantities of protein are required, transient expression in COS cells or the vaccinia system is a quick and suitable system to employ.

For production of larger quantities of protein, stable expression must be used because of the difficulty in scaling up transient expression into a bioreactor system. Stable expression in Chinese hamster ovary (CHO) cells is described in *UNIT 5.10*.

Some cell lines have successfully been used as hosts in production of viruses and useful proteins. These include the human embryonic lung cell line MRC-5 and the normal embryonic cell line WI-38. These cells are attachment growth–dependent and have a finite lifespan of ~50 generations, after which time the cells enter a senescent phase and begin to die.

Cell lines that have undergone transformation by virus or that have experienced alteration of chromosomes can exhibit a capacity for infinite growth as well as an ability to grow in suspension. Examples of such cell lines are HeLa cells from a human cervical cancer and Namalwa cells from a human lymphoma. There has been some reluctance to use these cell lines in production of clinical agents because of the possibility of transfer of tumorigenic agents to the product. For production of larger amounts of recombinant protein, stable expression is required and has been primarily performed in CHO cells, baby hamster kidney (BHK-21) cells, or myeloma cells (e.g., NS/O). These cell lines are capable of indefinite growth on a large scale and are suitable hosts for stable integration of heterologous DNA.

Stable expression results from integration into the host-cell genome of the gene for the expression of the heterologous protein. The integrated gene is transcribed efficiently and the protein is expressed persistently over many generations by the host cell. A stable producer-cell line typically provides ~1 to 10 mg of secreted protein per 10^9 cells per day (specific productivity). For monoclonal antibody production, productivity levels of 35 to 100 mg per 10^9 viable cells per day in myeloma cells (Bebbington et al., 1992; Shitara et al., 1994) and 15 to 110 mg per 10^9 viable cells per day in CHO cells (Page and Sydenham, 1991) are obtainable. Such levels may allow secreted-antibody titers of 1 to 1.5 mg/liter to be achieved in optimized large-scale systems; hence these systems have been popular in biotechnology. Where protein is accumulated intracellularly, it may reach little more than 0.1% to 0.5% of total cell protein. Thus, the focus has tended to be on secretion of protein where significant amounts of product are obtainable.

The obvious drawback associated with stable expression in mammalian cells is the time required to obtain stable productive cell banks (months) versus that required to obtain large amounts of non-post-translationally modified proteins in *E. coli* or large quantities of high-mannose-containing glycoprotein using yeast and insect cells (2 to 3 weeks). The advantages of obtaining the more complex proteins from mammalian cells include the ability to understand how these molecules interact in biological models both in vitro and in vivo. Using mammalian systems, much knowledge has been gained in the understanding of post-translational modification, protein quality control, and protein translocation. This knowledge ultimately facilitates improved expression in mammalian hosts.

Stable expression requires the transfer of the foreign DNA, along with the relevant DNA-based signals for transcription by RNA polymerase II, into the chromosomal DNA of the host cell (e.g., CHO). A suitable plasmid vector is required to carry the functions through to the host DNA. Vectors are commercially available from a variety of vendors—e.g., Invitrogen, Clontech, and Promega (see *SUPPLIERS APPENDIX*). A large variety of vectors are described in Pouwels et al. (1988). Suitable replicons contain 5 to 10 kb of DNA and usually are designed to contain phenotypic markers for selection in *E. coli* (e.g., Ap^r) and CHO cells ($DHFR^+$). Other features of appropriate plasmids include a promoter-distal cloning site along with other cloning sites; a replication origin for *E. coli*; a polyadenylation sequence from SV40 or bovine growth hormone; a eukaryotic origin of replication (e.g., SV40 or oriP); the gene for expression of the protein in a site proximal to the promoter; and a promoter and associated elements. Commonly used constitutive promoters for CHO cell applications are the SV40 early promoter (Moreau et al., 1981; Neuhaus et al., 1984), the adenovirus late promoter (McKnight and Tjian, 1986), and the cytomegalovirus (CMV) early promoter (Boshart et al., 1985). Transcriptional enhancers such as the human CMV enhancer (Boshart et al.,

BCU IASI CENTRAL UNIVERSITY LIBRARY

Gene Expression Using the Vaccinia Virus/ T7 RNA Polymerase Hybrid System

This unit describes a transient cytoplasmic expression system that relies on the synthesis of the bacteriophage T7 RNA polymerase in the cytoplasm of mammalian cells. To begin, a gene of interest is inserted into a plasmid such that it comes under the control of the T7 RNA polymerase promoter (p_{T7}). Using liposome-mediated transfection, this recombinant plasmid is introduced into the cytoplasm of cells infected with vTF7-3, a recombinant vaccinia virus encoding bacteriophage T7 RNA polymerase (see Basic Protocol 1). During incubation, the gene of interest is transcribed with high efficiency by T7 RNA polymerase. This transfection protocol is adequate for analytical purposes and is simple because no new recombinant viruses need to be made.

For large-scale work, the p_{T7}-regulated gene can be inserted into a second recombinant vaccinia virus by homologous recombination (*UNIT 5.13*) and used in combination with vTF7-3 to coinfect cells grown in suspension (see Basic Protocol 2) or used to infect OST7-1 cells (a stable cell line that constitutively expresses the T7 RNA polymerase; see Basic Protocol 3). Expressed protein is then analyzed by pulse-labeling (see Support Protocol) or by the methods detailed in *UNIT 5.14*, and purified as described in Chapter 6.

There have been several innovations to this vaccinia virus/T7 RNA polymerase hybrid expression system (see Background Information). One new development is the VOTE inducible expression system, which eliminates the need to use two recombinant viruses or a special cell line (see Basic Protocol 4).

NOTE: All culture incubations should be performed in a humidified 37°C, 5% CO_2 incubator unless otherwise specified.

NOTE: All reagents and equipment coming into contact with live cells must be sterile, and aseptic technique should be used accordingly.

LIPOSOME-MEDIATED TRANSFECTION FOLLOWING RECOMBINANT VACCINIA VIRUS (vTF7-3) INFECTION

BASIC PROTOCOL 1

This protocol begins with a plasmid vector containing the gene of interest at a site between p_{T7} and the T7 terminator (Figs. 5.15.1 & 5.15.2; also see Critical Parameters). This recombinant plasmid is then introduced via liposome-mediated transfection (*UNIT 5.10*) into cells already infected with vaccinia virus vTF7-3 (a recombinant virus expressing the T7 RNA polymerase gene). After harvesting, the cells are analyzed for expression of the gene product as described in *UNIT 5.14* or by pulse-labeling (see Support Protocol).

Materials

Recombinant plasmid: gene of interest subcloned into pTF7-5 or pTM1 vectors (available from B. Moss, e-mail *bmoss@nih.gov*; Figs. 5.15.1 and 5.15.2) or other plasmid containing the T7 promoter (e.g., pBluescript, Stratagene)
Confluent CV-1 cell monolayer (ATCC #CCL70; *UNIT 5.12*)
Complete DMEM-10 (*APPENDIX 3C*)
vTF7-3 vaccinia virus stock (ATCC #VR-2153)
Opti-MEM I reduced serum medium (Life Technologies)
Liposome suspension (Lipofectin or TransfectAce; Life Technologies)
6-well tissue culture dishes with 35-mm-diameter wells
Cup sonicator (385-W)

BOURNEMOUTH UNIVERSITY LIBRARY

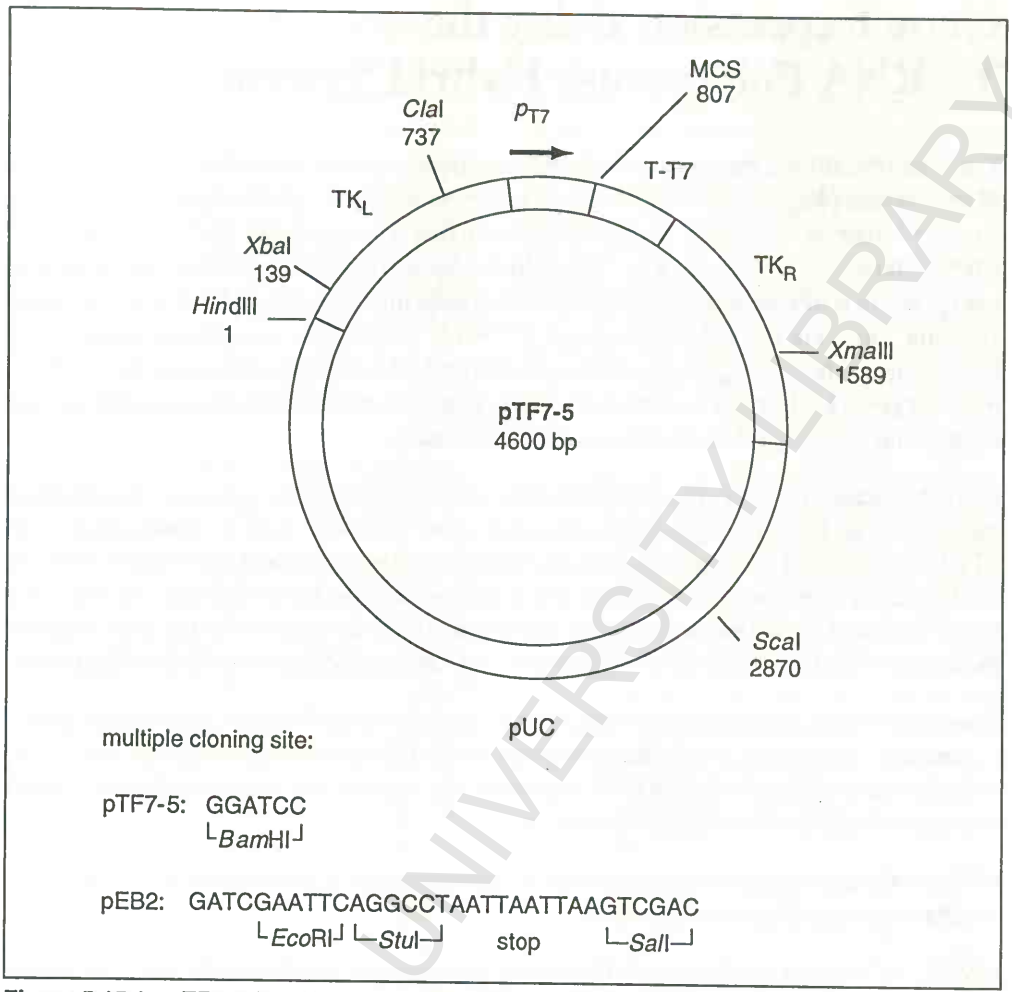

Figure 5.15.1 pTF7-5 (Fuerst et al., 1986) contains p_{T7} and a terminator, between which is a unique *Bam*H1 site for insertion of a gene. The derivative, pEB2 (Berger et al., 1988) contains unique *Eco*RI and *Stu*I sites followed by translation stop codons in all three reading frames. The expression cassette is flanked by segments of the vaccinia virus TK gene; thus, TK^- selection can be used for isolation of recombinant plaques (*UNIT 5.13*).

12 × 75–mm polystyrene tubes (Falcon)

Additional reagents and equipment for purification of plasmid (*APPENDIX 4C*)

1. Purify recombinant plasmid for transfection by CsCl/ethidium bromide centrifugation or PEG precipitation (*APPENDIX 4C*).

   Transfection will require 5 μg DNA/well of cells.

   When using the pTM1 plasmid (Fig. 5.15.2), make sure that the initiator ATG of the gene of interest is the ATG of the pTM1 NcoI site (see Critical Parameters). Determine that the correct construction has been obtained by restriction mapping and DNA sequencing.

2. The day before infection, seed wells of a 6-well tissue culture dish with 5×10^5 CV-1 cells/well in complete DMEM-10. Incubate until cells are near confluency (usually overnight).

   Cells should be counted with a hemacytometer (APPENDIX 3C).

3. Vortex stock of vTF7-3 to disperse clumps. Sonicate the lysate using a cup sonicator as follows.

   a. Fill the cup with ice water (~50% ice).

BAU IASI / CENTRAL UNIVERSITY LIBRARY

Stern-Volmer equations to give the quenching constant (K_{SV}) and the fraction of the initial fluorescence that is accessible to the quencher (see Basic Protocol 1).

The quenching of fluorescence of phosphoglycerate kinase (PGK) is shown plotted according to the Stern-Volmer equation (see Fig. 7.7.6A). The quenching levels off above 0.9 M succinimide and 0.6 M iodide, respectively, indicating that part of the fluorescence is unquenched by these quenchers. The different degrees of quenching by iodide and succinimide is due to the nature of the neighboring groups affecting access to the tryptophan. The plot of some of the data according to the modified Stern-Volmer equation (Fig. 7.7.6B) shows the fluorescence quenched by succinimide to be 42% of the total. The different degrees of quenching at 316 and 350 nm are due to the two tryptophans having substantially different values of λ_{max}, and hence different degrees of accessibility to solvent. Thus, taking into account the crystal structure of PGK, one of the two tryptophans, W333, is seen to be buried and inaccessible to quencher while the other, W308, is quenched with a quenching constant of $K_{SV} = 0.39$ liters/mol.

Another quencher, acrylamide, can quench the fluorescence not only of exposed but also of buried tryptophan residues based on its ability to diffuse through the protein structure. The efficiency of quenching is, therefore, a reflection of the tightness of packing and the dynamics of the protein. Figure 7.7.11 shows the results of acrylamide quenching of the

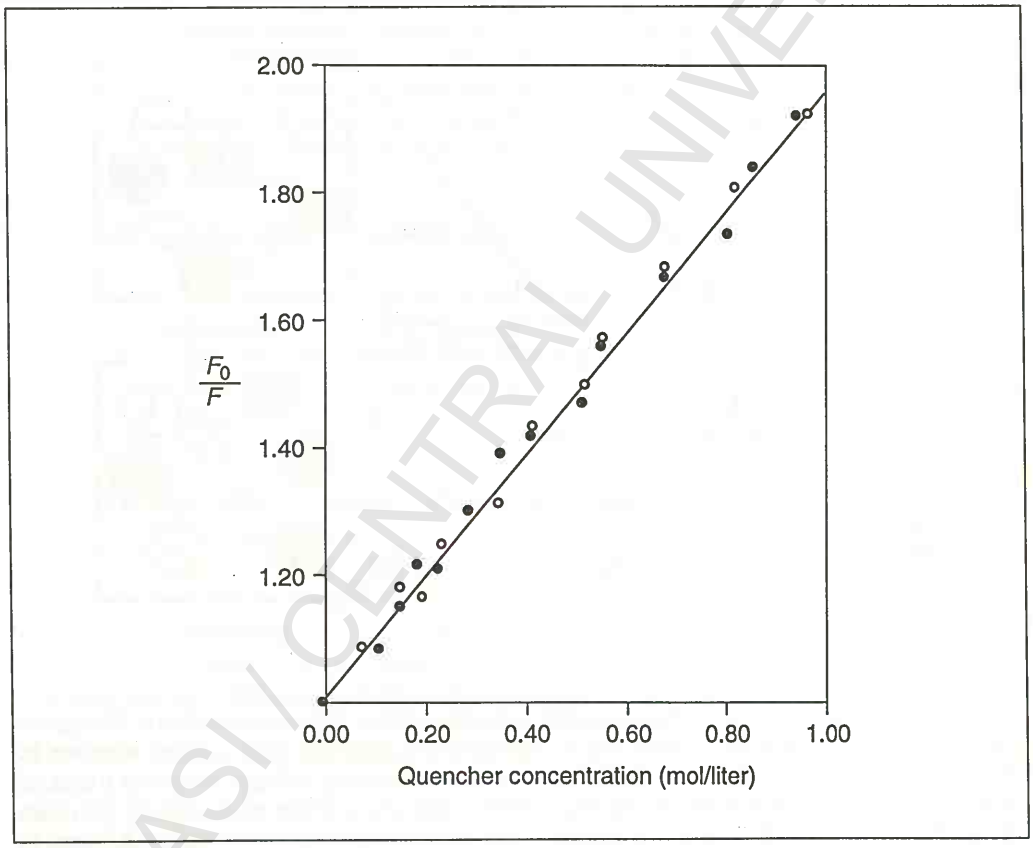

Figure 7.7.11 The quenching of buried tryptophan fluorescence in 3-phosphoglycerate kinase (PGK). In the presence of 1.12 M succinimide (shown to quench the exposed tryptophan fluorescence; see Fig. 7.7.6), fluorescence is further quenched by acrylamide, which is able to gain access to the buried tryptophan. Fluorescence was measured at 316 nm (filled circles) and at 350 nm (open circles) and plotted according to the Stern-Volmer equation (see Basic Protocol 2, step 4). Fluorescence intensities were corrected for dilution and for quencher absorbance using $\varepsilon_{295} = 0.236$ for acrylamide. The linear plot indicates the quenching of a single residue. Measurements made using a Perkin-Elmer MPF3-L. Reprinted from Varley (1991) with permission of Elsevier Science.

BRAWASI / CENTRAL UNIVERSITY LIBRARY

buried W333 of PGK (in this experiment the more exposed W308 is quenched by succinimide). The linearity of the plot, combined with the coincidence of the quenching measured at 316 and 350 nm (in contrast to Fig. 7.7.6), shows that a single tryptophan only is being quenched by the acrylamide. A quenching constant $K_{SV} = 0.94$ liters/mol is obtained from the slope. In general, bimolecular rate constants for quenching, which reflect more directly the dynamics of the protein, can also be calculated if fluorescence lifetime measurements are available (see discussion of Stern-Volmer equation in Basic Protocol 2; see also Eftink and Ghiron, 1981).

Fluorescence Depolarization

If a polarizer is placed in the excitation beam, the radiation passing through the sample solution will be plane-polarized. This beam will now be absorbed only by those chromophores whose transition dipoles are in the same plane (see Fig. 7.7.12). If the chromophore does not rotate within 10^{-8} sec (see Fig. 7.7.7), the fluorescence will be emitted with the same degree of polarization and will pass through a second polarizer (or analyzer) oriented parallel to the first polarizer. If, on the other hand, the excited chromophores rotate before fluorescence takes place, emission will take place from a smaller number of molecules reoriented with transition dipoles parallel and perpendicular to the exciting radiation

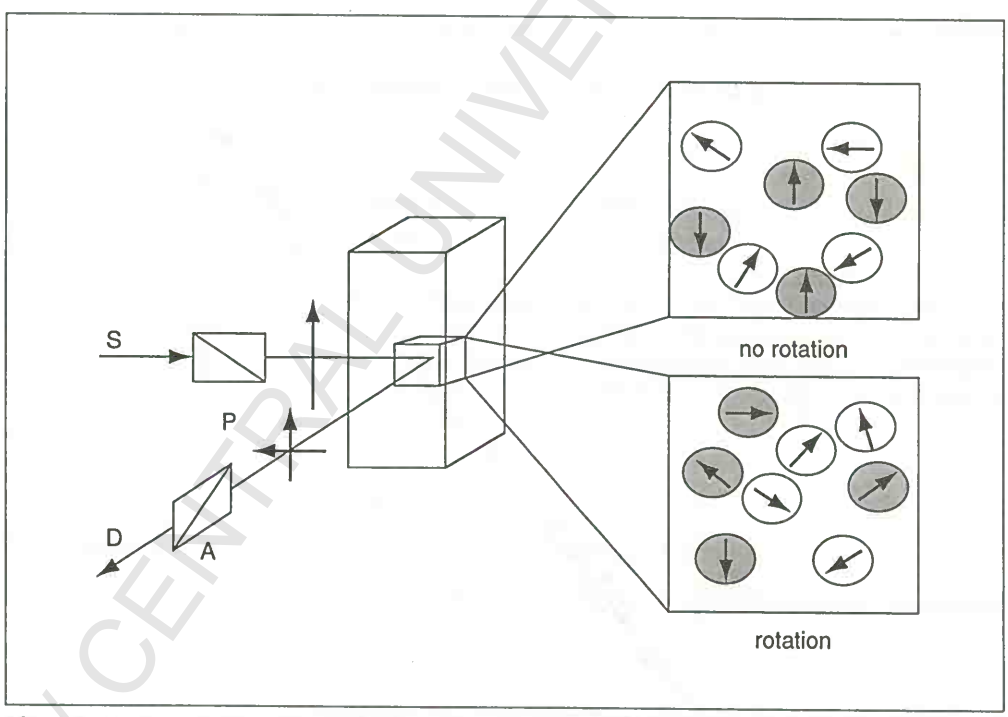

Figure 7.7.12 Depolarization of fluorescence indicates rotation of the chromophore. Monochromatic radiation from the source (S) has all but the vertically polarized electric vector removed by the polarizer (P). This is absorbed only by those molecules (see Fig. 7.7.5) in which the transition dipole of the chromophore is aligned vertically. In the case where these molecules do not rotate appreciably before they fluoresce ("no rotation"), the same molecules will fluoresce (indicated by shading) and their emitted radiation will be polarized parallel to the incident radiation. The intensity of radiation falling on the detector (D) will be zero when the analyzer (A) is oriented perpendicular to the polarizer. In the case where the molecules rotate significantly before fluorescence takes place, some of the excited chromophores will emit radiation with a horizontal polarization ("rotation") and some with a vertical polarization. Finite intensities will be measured with both parallel and perpendicular orientations of the analyzer. The fluorescence from the remainder of the excited molecules will not be detected. The heavy arrows on the left of the diagram illustrate the case where there is rotation.

Gel-Filtration Chromatography

Gel filtration (GF) separates proteins solely on the basis of differences in molecular size. Separation is achieved using a porous matrix to which the molecules, for steric reasons, have different degrees of access (smaller molecules have greater access and larger molecules less). The matrix is packed into a chromatographic column, the sample mixture applied, and the separation accomplished by passing an aqueous buffer (the mobile phase) through the column. Protein molecules that are confined in the volume outside the matrix beads will be swept through the column by the mobile phase and the sample is thus eluted in decreasing order of size. The protein zones eluted are detected by an in-line UV monitor and fractions are collected for subsequent specific analysis or further preparation steps.

GF is often used to condition samples prior to further purification by adsorptive techniques. It is also frequently used in the final polishing stage (*UNIT 8.1*) to remove a few remaining contaminants with surface properties similar to the target protein (e.g., for polishing monomers from oligomers).

Three basic protocols are provided in this unit, corresponding to the major applications of gel filtration. GF is used for desalting or group separation (see Basic Protocol 1), in which the target protein and contaminating solutes differ substantially in molecular size. It is also used for protein fractionation (see Basic Protocol 2), where proteins with only a small size difference must be separated. A third application is in characterizing the molecular dimensions of proteins (see Basic Protocol 3). A Support Protocol is also provided for calibrating GF columns to be used in estimating molecular size.

NOTE: Among the items referred to in this unit, Sephadex, Sephacryl, Superdex, Superose, and HiLoad are trademarks of Amersham Pharmacia Biotech; Bio-Gel and Bio-Sil are trade marks of Bio-Rad; and Toyopearl and TSK SW are trademarks of Toyo Soda.

STRATEGIC PLANNING

Selecting Matrix and Column for Desalting

The exclusion limit—i.e., the smallest-sized protein molecule that will be excluded from the pores of the matrix—is the most important factor in selecting a matrix for desalting. If the protein is able to permeate the matrix, flow-dependent zone broadening (*UNIT 8.1*) will occur, reducing the resolution. On the other hand, gels of very small pore size generally contain more matrix, and thus have smaller separating volumes. A gel of sufficiently small exclusion limit, but not smaller, should therefore be selected. Another factor to take into consideration is the particle size of the matrix. This should not be too small because the pressure drop over the column is inversely proportional to the square of the particle size; this factor is especially important for gravity flow columns.

The selection of column dimensions (i.e., the bed volume of the column) is influenced by the amount of sample that is to be processed. Columns for desalting are typically short and wide to accommodate large sample volumes and keep the processing time short. Because the zone broadening of the column will have a limited effect on the peak width in desalting as compared to other applications of gel filtration—e.g., protein fractionation—short columns run at high flow rates are used for large-scale desalting. The typical length of columns for laboratory use is ~10 cm.

Columns for desalting vary greatly in size and sophistication, ranging from Pasteur pipets plugged with glass wool to prepacked high-performance GF columns. The scale of

operation for which they are used also varies widely, with applications ranging from micropreparative cleanup of a 50-µl reduction/alkylation mixture using a 0.9-ml column to industrial de-ethanolization of 12 liters of human serum albumin using a 75-liter column. Incidentally, columns for both these procedures may be packed with Sephadex G-25—of course, of different particle size.

Some gel-filtration media suitable for laboratory-scale desalting are listed in Table 8.3.1, and some empty columns that can be used with these media are listed in Table 8.3.2. A partial compilation of disposable prepacked columns for desalting is found in Table 8.3.3. This table also contains information about spin columns for use with a centrifuge. Spin columns require special techniques, and they are presently not widely used for desalting proteins; therefore no protocols for their use have been included in this unit. More information about spin columns can be obtained from the suppliers.

Selecting Matrix and Column for Protein Fractionation

Suitability of a gel for protein fractionation may be judged from "typical runs" made with synthetic protein mixtures, the results of which are published by suppliers. The solute of interest should ideally be eluted in the first part of the chromatogram, but not too close to the void volume. A matrix with a distribution coefficient (see Basic Protocol 3) of ~0.2 to 0.4 has been reported to yield maximum resolution (Hagel, 1989). This corresponds to an elution volume of ~1.5 to 2 times the void volume. A long bed and a matrix with a large pore volume will increase the peak-to-peak distance between the proteins and thus increase the resolution of the system (also see Critical Parameters and *UNIT 8.1*). Another way to increase resolution is to employ a GF matrix of small particle size, which will reduce the zone width of the protein bands. The flow rate will also affect resolution. As in the case of desalting, the maximum sample volume that can be processed depends upon the bed volume and the pore volume of the packed bed. Thus, there are many parameters to consider when optimizing protein fractionation by GF. In the worst case, a suitable matrix may have to be found by trial and error.

Commercial prepacked columns for protein fractionation often sacrifice column length and pore volume in favor of small particle size. This results in columns that are optimized for fast separation at the expense of some reduction in the maximum sample volume that can be loaded. Therefore, traditional columns packed in the laboratory are often still a

BCU IASI - CENTRAL UNIVERSITY LIBRARY

good alternative for purification of large volumes of sample. If time is critical in the separation (e.g., in proteinase removal), fast column operation is of course advantageous. Matrices of large particle size will permit protein fractionation at low operating pressure. Some matrices suitable for protein fractionation are listed in Table 8.3.4, and some empty columns suitable for use with these media are listed in Table 8.3.5. Table 8.3.6 lists some prepacked columns for protein fractionation. Columns and media are selected on the basis of the difficulty of the separation (i.e., how small the size difference is between the proteins to be separated) and whether scaleup will be required (i.e., the availability of a variety of

BOSTON UNIVERSITY MEDICAL CENTRAL LIBRARY

columns with different diameters that can be packed with bulk media facilitates linear scaleup).

A matrix of small particle size will permit preparation of columns of high efficiency (i.e., low zone broadening) at the expense of high pressure drops and greater cost. Also, smaller particles generally have smaller pore volumes. The net effect of the relationships between these parameters is that the prepacked columns listed in Table 8.3.6 have resolving power of the same order of magnitude, although protein fractionation may be carried out faster on the columns that have particles of small size.

A final factor to consider in choosing a matrix for protein fractionation is the likelihood of matrix-solute interactions (e.g., as in the case of lectins on gels containing glucose-type structures).

Selecting Matrix and Column for Molecular Size Determination

A matrix with high resolving power is recommended for determination of molecular size as well as for protein fractionation (see Table 8.3.4, Table 8.3.5, and Table 8.3.6 for

BCU LRS / CENTRAL UNIVERSITY LIBRARY

matrices and columns suitable for both these applications). However, certain other criteria that are important for selecting a matrix and column for size determination differ from those for protein fractionation. First, when analyzing samples containing several proteins of varying molecular size (e.g., protein digests) a matrix of sufficient separation range is needed. As selectivity inherently limits separation range, optimal separation range may not be achieved using a matrix of high selectivity. Second, because peak broadening is not critical as long as the peaks are resolved, short (e.g., 30-cm) columns operated at high flow rates may be used. However, in situations where the effluent is continuously monitored with a mass-sensitive detector (see Basic Protocol 3), complete resolution between peaks is essential. In this case the criteria used for protein fractionation may be applied.

BASIC PROTOCOL 1

DESALTING (GROUP SEPARATION)

Desalting, or group separation, is used to separate the target protein from low-molecular-mass contaminants. The purpose might be to remove salt prior to lyophilization, or to remove low-molecular-mass reagents—e.g., a reductive cleavage mixture from a preparation step (*UNIT 11.1*) or polybuffer from chromatofocusing (*UNIT 8.5*). Desalting is also used to change from one buffer to another—e.g., to decrease ionic strength prior to ion-exchange chromatography (*UNIT 8.2*). The pore size of the matrix is selected to exclude the protein of interest while allowing maximum permeation of the contaminants. This is beneficial in three ways. First, because the protein does not penetrate into the pores, little dilution of the sample will take place except where the sample volume is very small. Second, because the protein is unable to diffuse into the pores, no flow-sensitive zone broadening (*UNIT 8.1*) that results from slow mass-transfer will take place. Hence, the flow rate may be kept high during the desalting. Third, because the protein and the low-molecular-mass solutes are maximally separated, very large sample volumes may be applied before contamination of the protein band becomes evident. Thus, very large sample volumes may be applied and desalted in a short time without dilution of the sample.

The procedure described here uses a closed column system and a pump; annotations explain variations needed in some of the steps if an open-bed column and gravity flow are used. The GF matrix is swelled, the column is packed, and the void volume and total volume of the column are determined in preliminary runs using high- and low-molecular-weight solutes. This information is used to determine the maximum sample volume to apply for the unknown protein to be desalted. Guidelines for estimating approximate sample volumes to use for desalting are also given. Alternative steps are provided for using this procedure either to determine elution volume or to desalt a protein for preparative purposes (or further analysis). Elution volumes must be determined to ascertain the exact void volume and total volume of a column in preparation for desalting. It is also necessary to measure the elution volume for certain protein analyses—e.g., for determining molecular size (also see Basic Protocol 3).

Fraction collector (optional; Fig. 8.3.1)

NOTE: Small-scale desalting of multiple samples may be carried out using spin columns and a centrifuge. At present, spin columns are primarily used for preparing microliter-sized samples of oligonucleotides; however, they are equally useful for small-volume protein samples. As the procedure is different from that described here, manufacturer's instructions should be consulted (see Table 8.3.3 for suppliers).

BCC HSL CENTRAL UNIVERSITY LIBRARY

Prepare gel

If GF matrix is supplied dry:

1a. Calculate the amount of dry matrix needed from the swelling factor given by the manufacturer and the approximate bed volume of the column to be packed. Add the calculated amount of dry gel to a volume of GF desalting buffer equal to twice the calculated final gel volume (i.e., twice the approximate bed volume of the column).

2a. Carefully stir suspension with a glass rod. Let gel swell overnight at room temperature or for 3 hr in a 90°C water bath, stirring as needed to keep gel in suspension.

Do not use a magnetic stirrer, as this may break fragile gel particles.

3a. Allow gel bed to settle, then remove fines and broken beads by decanting the hazy solution. Repeat decantation (4 or 5 times if necessary) until bed settles as a sharp zone, then dilute so that final slurry is 50% (v/v) settled gel and 50% (v/v) GF buffer.

Careful removal of fine particles will prevent the nets that support the column end pieces from becoming blocked, and will also permit a higher flow rate through the column.

If GF matrix is supplied preswollen:

1b. Wash gel with an excess of GF buffer on a Buchner or sintered-glass funnel to remove storage buffer.

With some products, the gel slurry is obtained by simply shaking the gel bottle, and this can be used to pack the column without further preparation. If this type of gel is used, skip steps 1b to 3b and proceed directly to step 4.

Gel particles may adhere to the glass wall of the funnel; therefore, to avoid contamination from other types of gels (e.g., ion-exchange media), it is important to ensure that glassware used is clean.

2b. If gel contains fines, remove by decantation as in step 3a.

3b. Dilute so that final slurry is 50% (v/v) settled gel and 50% (v/v) GF buffer.

Pack column

4. Examine column to ensure that it is clean and that the support nets are undamaged. If necessary, supply column with new support nets.

5. Mount column on a stable laboratory stand, using a carpenter's level to ensure that it is vertical. Equip column with an extension that together with the column will hold the complete volume of the gel slurry (i.e., twice the volume of the settled gel).

If <50% of the column volume is to be packed, there is no need for a column extension.

6. Remove air from outlet tubing and end piece of column by injecting GF buffer into outlet tubing (using syringe or peristaltic pump) until support net is covered with 0.5 cm of buffer. Close outlet of column.

7. Inject GF buffer into inlet tubing of adaptor until net is wetted, while holding outlet upwards to ensure that air easily escapes from net. Place adaptor in a beaker containing GF buffer until it is time to use it.

8. Swirl gel slurry from step 3a or b and pour entire slurry into column along a glass rod tilted toward the inner wall of the column or column extension. Fill the remaining space with GF buffer by carefully pouring buffer along glass rod so as to cause minimum disturbance of the gel layer. Put lid on column extension (or put top adaptor on column).

Small columns (e.g., 1-cm i.d., 5-cm length) to be used for preliminary experiments where optimum resolution is not critical may be quickly prepared by adding the gel slurry to the

PCU IASI / CENTRAL UNIVERSITY LIBRARY

chromatographic tube, letting the gel settle by gravity, and washing the bed with one column volume of GF buffer before applying the sample.

9. Fill buffer reservoir with GF buffer and place at a level higher than the pump. Connect reservoir to pump using a large-i.d. tube.

   This step is to ensure a free flow of buffer to the pump head.

10. Purge pump with GF buffer and attach outlet from pump to inlet of column or column extension. Open outlet of column and start pump at flow rate recommended by manufacturer for the gel/column combination used. Continue flow until height of gel bed becomes constant (typically 1 to 4 hr).

    If no manufacturer's recommendation is available, use a flow rate 50% higher than that to be used in the separation.

    If column is to be packed by gravity flow—i.e., by attaching the buffer reservoir directly to the inlet of the column—the actual flow rate must be monitored (e.g., by continuously weighing the effluent, or in the simplest case, by using a graduated cylinder) or controlled by a pump placed after the column. In the latter case it is necessary to check that the free gravity flow exceeds the pump flow—i.e., that the pump is serving to reduce the flow to a constant value.

    The flow rate caused by gravity depends upon the hydrostatic pressure, determined by the difference in height between the air inlet in the buffer reservoir and the outlet tubing from the column. However, because the pressure drop over the column increases with the height of the packed bed, the free gravity flow rate will decrease during packing if the hydrostatic pressure is kept constant. Gravity flow rate may be increased by lowering the outlet tube or raising the buffer reservoir.

11. Turn pump off, close column outlet, remove column extension, adjust bed height if necessary, and adjust inlet adaptor so that it is flush with the bed surface.

    Avoid trapping air under the support net.

    Adjustment of the bed height is recommended only to remove excess gel. This is done by carefully swirling the upper part of the gel surface with a spatula and sucking the excess slurry out with a Pasteur pipet or tubing attached to a pump. If a crater or uneven surface is produced, the gel should be swirled so that a sharp bed surface is obtained before adjusting the inlet adaptor atop the bed. If the bed is too short the column should be repacked, although in most cases the old gel can be reused and added to new slurry prepared as in steps 1a to 3a or 1b to 3b before repacking.

12. Reattach column to pump, open column outlet, and resume flow conditions used in step 10 for 1 hr to stabilize column bed height. Readjust the adaptor so that it is flush with the new bed surface.

    In some cases it is desirable to lower the inlet adaptor a few millimeters into the gel surface to make sure that there is contact between adaptor and gel.

    Stabilizing the bed at a higher flow rate than that to be used during the separation will prevent the bed from shrinking as a result of "after-packing" during the run. If a gap appears between the adaptor and the bed surface, step 12 must be repeated at an increased flow rate before experiments are carried out. A space between the adaptor and the bed surface will act as a mixing chamber; the effect on separation will depend on the separation problem at hand.

13. Inspect packed bed visually for cracks, trapped air, and particle aggregates by observing the light scattered from a light source held behind the column. Chromatograph a colored marker (2 mg/ml Blue Dextran 2000 or 0.2 mg/ml vitamin B_{12}) as in steps 20 to 23, and ascertain that the zone produced is horizontal and sharp.

    Quality of the packed bed need not be as high for desalting as for protein fractionation (see Basic Protocol 2); therefore evaluation of the packed bed may be performed by visual

B.C.U. „M. EMINESCU" IAŞI
CHIMIE

inspection. However, it is important for it to be free of cracks and for a colored sample to produce a sharp horizontal zone.

Air bubbles would be a major problem and should be avoided at all costs (see Troubleshooting).

If column is to be stored, GF buffer containing 0.02% (w/w) sodium azide or 20% (v/v) ethanol as antibacterial agents should be prepared, then 2 column volumes of this mixture should be pumped through the column. The outlet is then closed and the column stored in the buffer/antibacterial agent at room temperature for several months. See recipe for GF buffer for precautions concerning azide.

Prepare and test the GF system

14. Calculate amount of GF buffer necessary for the run and filter this amount plus a 50% excess through a 0.22-μm filter. Adjust pH if necessary and pour filtered buffer into buffer reservoir.

    If the column is going to be used for a prolonged time, it is good practice to continuously deaerate the GF buffer by heating the buffer slightly with heat from a light bulb, or to use a degasser.

15. Assemble GF system according to manufacturer's instructions or Figure 8.3.1, placing detector and chart recorder (if used) in line but leaving column off line. Attach buffer reservoir to pump and purge pump with GF buffer with column off line.

    If the system is run by gravity flow alone, the risk of the column running dry may be eliminated by placing the end of the outlet tubing higher than the inlet adaptor or placing a loop of the tubing from the reservoir with its bend at a lower level than the outlet.

    Detection of salt may be accomplished in line by conductivity or off line by flame photometry or conductimetry. Colorimetric detection of proteins is readily done at 280 or 254 nm; the latter wavelength provides higher sensitivity. Refer to Chapter 3 for specific methods of protein detection.

16. Connect outlet of pump to column via the injection valve, run system with GF buffer at flow-rate settings to be used for separation, collect fractions with fraction collector, and note actual flow rate of the pump (e.g., by weighing collected fractions or measuring them with a graduated cylinder).

    If the concentration of the solute is detected by in-line monitoring, use of a two-channel recorder set at different sensitivities (e.g., 100% and 10% full-scale) is recommended to ensure that the peaks of unknown solutes are not off-scale.

    The actual flow rate of the system must be determined with the column installed, because the flow rate from a peristaltic pump or similar device depends upon the back-pressure of the system.

Determine separating volume of column

17. Determine the void volume of the system (V_o) by running a void marker and obtaining the elution volume according to steps 20 to 23.

    The sample volume for determination of void volume and total liquid volume (steps 17 and 18) is not critical and may typically be 1% to 2% of the bed volume. However, correction of the calculated elution volume is needed if large sample volumes are applied (see annotation to step 23a). See Figure 8.3.2 for graphical depiction of void and total liquid volume.

    The markers for void volume and total liquid volume may be mixed and run together.

    Void volume (V_o) is typically 30% to 33% of the bed volume of a nonrigid (e.g., agarose) gel and 36% to 40% of the bed volume of a rigid (e.g., silica) gel.

18. Determine the total liquid volume of the system (V_t) by running a total liquid volume marker and obtaining the elution volume according to steps 20 to 23.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Total liquid volume (V_t) is typically 85% to 95% of the geometric bed volume ($\pi r^2 L$, where r is the inner radius of the column) for a nonrigid gel and 70% to 80% of the bed volume for a rigid gel. Because solute-matrix interactions may occur, it is advisable to check that the total liquid volume is smaller than the bed volume and perhaps run several different total liquid volume markers to confirm the result.

19. Calculate the separating volume of the column (V_i) as $V_t - V_o$.

The separating volume (V_i) is the amount of liquid that will pass through the column from the point where large proteins begin to emerge to the point where small solutes are eluted. It is equal to the pore volume of the bed, which is typically 50% to 65% of the bed volume of a nonrigid gel and 30% to 50% of the bed volume of a rigid gel.

Prepare, apply, and chromatograph the sample

20. Dissolve sample to be desalted in GF buffer. Filter through a 0.22-µm protein-compatible filter.

If possible, let sample solution reach room temperature before being applied to column to reduce viscosity effects. This is more important for large sample volumes.

The influence of the sample volume on the resolution (see Critical Parameters) is related to the need for column efficiency (see Basic Protocol 2 and UNIT 8.1). Too large a sample volume may ruin the separation of closely eluting proteins in a separation where high efficiency and narrow peaks are required. This is of primary interest in protein fractionation (see Basic Protocol 2), whereas in desalting, conditions are chosen to yield maximum separation of the protein from contaminants. To this end, column efficiency is less important, and very large sample volumes may be applied. See Critical Parameters for guidelines on optimal sample concentration.

When GF is performed for analytical purposes, the sample concentration should be as small as possible within the sensitivity of the detection method employed. For preparative purposes, on the other hand, the concentration should be as high as possible. The limiting factor in the latter case is the viscosity of the sample divided by the viscosity of the GF buffer (relative viscosity). At relative viscosities >1.5, the hydrodynamic instability of the trailing edge of the zone may cause distortion of the protein zone (resulting from invasion of less viscous eluant into the more viscous zone; called "viscous fingering"), which will ruin the separation. It is generally safe to use protein concentrations up to 50 mg/ml and in some cases up to 70 mg/ml, whereas concentrations of 100 mg/ml often result in viscous

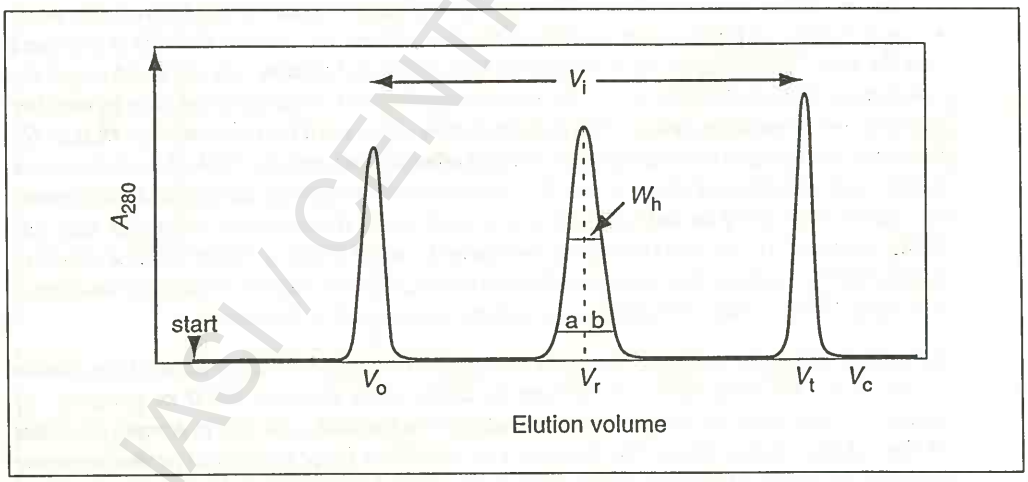

Figure 8.3.2 Chromatogram illustrating the separating volume (V_i) of gel filtration as determined by the void volume (V_o) and the total liquid volume (V_t). The total bed volume (V_c) is equal to the total liquid volume plus the matrix volume. Column efficiency is calculated as $N = 5.54(V_r/W_h)^2$, where N is the efficiency of the column in terms of number of theoretical plates, V_r is the elution volume of the peak, and W_h is the peak width at half peak height. The symmetry of the peak is calculated at 10% peak height as b/a, where b is the width of the tailing part of the peak and a is the width of the leading part of the peak.

BOGAZIÇI UNIVERSITY LIBRARY

fingering. However, when large sample volumes are applied—e.g., in desalting—the low dilution factor will result in a high concentration of protein in the peak, hence lower concentrations than these may be required to avoid viscosity effects.

21. Open outlet from column, turn on pump, and let two bed volumes of GF buffer pass through the column. Turn on detector and recorder and allow baseline to stabilize.

22. Load sample applicator with the appropriate volume of sample for desalting, not exceeding the separating volume determined in step 19. Switch the sample application valve to the load position and put a start mark on the chart recorder paper (or start a stopwatch if no chart recorder is used).

    Smaller sample volumes are used for protein fractionation than for desalting, and much smaller sample volumes are used for analysis.

    Before injecting, flush injector loop with excess sample to avoid trapping air bubbles, which otherwise may end up in the top of the column.

    If the separating volume of the column has not been determined, the maximum sample volume may be estimated as ~50% of the bed volume for nonrigid media and ~30% of the bed volume for rigid media. For a first attempt at desalting, 50% of these volumes should be applied (i.e., 25% and 15% of the bed volume for nonrigid and rigid media, respectively).

    If an open-bed column is used, gently add GF buffer to the top of the column with a Pasteur pipet or similar device, then open the outlet from the column and continue adding GF buffer until two bed volumes of buffer have passed through. Let the last portion of buffer penetrate the gel without the gel surface becoming dry; this is facilitated by using a top filter on the bed. Gently apply the sample to the clear gel surface or the top filter using a micropipet (or a Pasteur pipet if large volumes of sample are to be desalted).

23a. *To determine elution volume:* Pass GF buffer through the system at the appropriate flow rate and follow detector response with recorder while collecting fractions. Construct a chromatogram and calculate elution volume as the time from the start point to the apex of the peak for the protein (or other solute) multiplied by the flow rate of the pump (as determined in step 16).

    If large sample volumes are being applied, the correct elution volume of the peak is obtained by subtracting half the applied sample volume from the apparent elution volume.

    For determination of void volume as in step 17, the fractions that emerge between the point where a volume of buffer equal to 25% of the bed volume has passed through the column and the point where buffer volume equal to 50% of the bed volume has passed through the column are analyzed (either in line by monitoring detector response or off line by another method; see annotation below). For determination of the total liquid volume as in step 18, fractions emerging between the point where a buffer volume equal to 75% of the bed volume has passed through and that where 125% has passed through are analyzed. To determine the elution volume of an unknown protein sample (as in determining molecular size; see Basic Protocol 3), fractions emerging between the point where a buffer volume equal to 25% of the bed volume has passed and that where 125% has passed through are analyzed. Allowing 125% to pass through will permit the entire peak to be traced.

    If fractions are to be collected for subsequent off-line analysis to determine where elution occurs (e.g., by photometry at 280 nm to detect Blue Dextran 2000 or proteins, or conductivity to trace the salt peak), start and stop the fraction collector to sample fractions at the volumes stated above. The fraction size should be large enough to permit accurate assay of the solute of interest; often 1 ml or 2% of the bed volume (whichever is smallest) is a suitable fraction size. The prefraction (i.e., the amount of liquid eluted from the point of sample application to the start of fraction collection for analysis) should be sampled in a vessel of known weight. The elution volume is calculated from the volume of the fractions by adding half the volume of the peak fraction and the volume of the prefraction, then subtracting half the sample volume. For dilute aqueous buffers (e.g., 0.5 M) a density of

BCU IASI / CENTRAL UNIVERSITY LIBRARY

1 may be assumed for converting weight to volume. If the experiment will take a long period of time, it is advisable to minimize evaporation by sealing the fraction cups with Parafilm.

If an open-bed (gravity flow) column is used, carefully add a volume of GF buffer that corresponds to the void volume of the column reduced by half the sample volume—unless the sample volume is <4% of the bed volume, in which case add 1 void volume of buffer. If the column is operating correctly, the effluent collected should contain no protein. Add GF buffer in ≤1-ml increments if the column has a bed volume <50 ml, collect fractions, assay for proteins, and calculate elution volumes as described above.

23b. *To desalt a protein:* Pass a volume of GF buffer equal to the void volume reduced by half the applied sample volume through the column, and collect a waste fraction. Place a vessel that can hold 1.5 times the applied sample volume under the column, then add a volume of GF buffer equal to the applied sample volume. Collect the desalted protein.

Depending upon the efficiency of the desalting system, these quantities may have to be adjusted (i.e., the volume collected in the second fraction may need to be decreased in order to preclude contamination from substances that elute later). If system effects (e.g., mixing after the column) are substantial or the column is badly packed (e.g., contains cracks in the bed), it will be necessary to pass more GF buffer through the column than the void volume minus half the sample volume before sampling the protein (see Critical Parameters). Figure 8.3.3 shows a sample chromatogram of optimized desalting of 400 ml hemoglobin.

The desalting step may be continuously monitored by simultaneous in-line detection of the protein zone by absorbance at 280 nm and in-line detection of the salt peak by conductivity.

24. Wash column with ≥1 column volume of GF buffer containing an antibacterial agent. Close column outlet and store column.

See recipe for GF buffer for acceptable antibacterial agents.

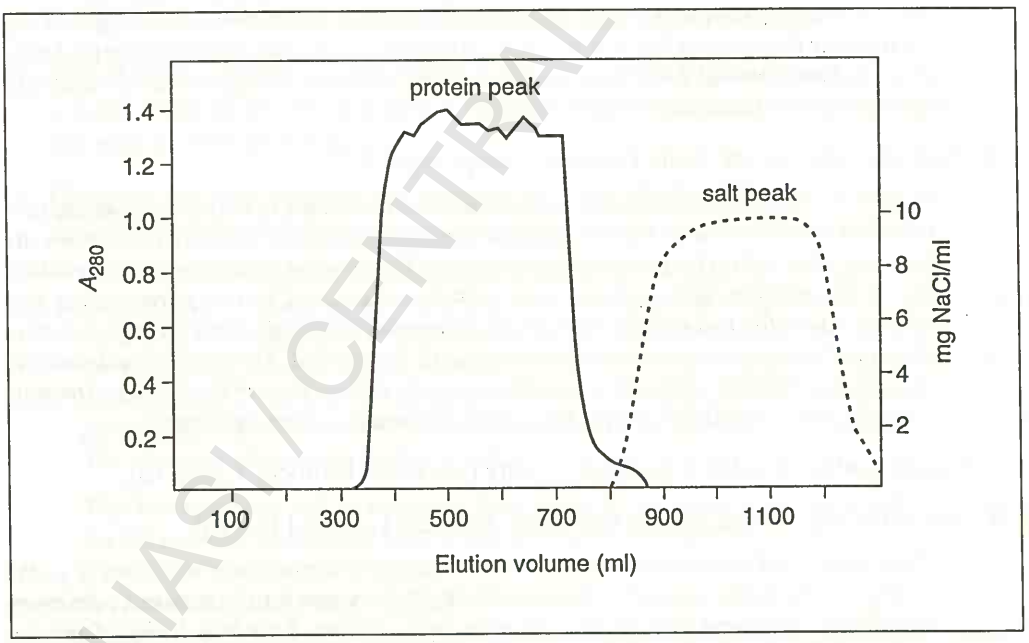

Figure 8.3.3 Chromatogram illustrating desalting of proteins by gel filtration. A 4 × 85–cm column packed with Sephadex G-25 is used. The sample consists of 400 ml hemoglobin (protein peak; solid line) in NaCl (salt peak; broken line). Note that the sample volume is close to the pore volume of the packed matrix, i.e., 490 ml. No correction for sample volume has been made. Calculation from the figure yields V_o = 560 ml – 200 ml = 360 ml, which is 31% of the geometric column volume (V_c). PROTEIN FRACTIONATION

Protein fractionation refers to the separation of proteins of similar molecular size for purification purposes. The objective may be to separate dimer and higher aggregates from a pharmaceutically active protein or peptide. Requirements for the column and system are therefore substantially higher for protein fractionation than for desalting.

The same materials and methodology described for desalting are used for protein fractionation. However, selection of matrix and column (see Strategic Planning) is more critical in this procedure, as are the quality of the column packing and control over experimental conditions (e.g., temperature and flow rate). The protocol includes steps for determining the column efficiency (also see *UNIT 8.1*) to evaluate the fitness of a packed column for use in protein fractionation.

Materials

GF matrix (see Table 8.3.4) or prepacked GF column (see Table 8.3.6) with appropriate selectivity for protein of interest (also see Strategic Planning and see Critical Parameters)
GF fractionation buffer (see recipe)
Colored marker: 0.2 mg/ml Blue Dextran 2000 or 0.2 mg/ml vitamin B_{12}
Low-molecular-weight marker (e.g., 5 mg/ml acetone or 2 M sodium chloride)
Protein sample to be fractionated
GF chromatography column (see Critical Parameters and Table 8.3.5)

Prepare column

1. Prepare GF matrix as described in the desalting procedure (see Basic Protocol 1, steps 1a to 3a or 1b to 3b) using GF fractionation buffer wherever GF buffer is indicated.

   It is generally difficult to prepare columns of maximum efficiency using a GF medium with a small (e.g., 10-μm) particle size. The need to scale up the procedure should be considered when selecting medium and column (see Strategic Planning and Critical Parameters).

   The GF fractionation buffer must be selected in light of the method planned for testing purity of the final protein fraction (step 11), as this may put special restrictions on the buffer (e.g., sodium azide absorbs light at 254 nm and will also interfere with the anthrone reaction used for assaying carbohydrates).

2. Pack the column (see Basic Protocol 1, steps 4 to 12).

   Because protein fractionation puts high demands on the quality of the packed column, care must be taken in selecting columns of proper design. Columns for protein fractionation are typically 30 to 100 cm long, depending upon the difficulty of the separation and the particle size of the medium used. Columns used must be constructed so that parts coming into contact with buffer and sample are made of appropriate materials. Long tubings and other sources of dead space or mixing chambers should be avoided. The pressure resistance of the column should be compatible with the expected pressure drop of the bed. See Strategic Planning and Critical Parameters for details concerning column selection.

3. Check quality of column packing visually (see Basic Protocol 1, step 13).

4. Assemble and test the system (see Basic Protocol 1, steps 14 to 16).

   Place system and column in an environment not subject to temperature variations (e.g., the column should not be exposed to direct sunlight). If the system is to be used in a cold room, the influence of temperature on viscosity must be considered. Zone broadening of proteins and the pressure drop of the system are proportional to the viscosity of the buffer, and the flow rate will have to be adjusted accordingly.

   Successful, reproducible protein fractionation requires a constant flow rate. This may be achieved using a peristaltic or high-precision pump whose flow rate is regularly checked. Continuous monitoring of the effluent is necessary to ensure proper sampling of the fraction

BCU IASI / CENTRAL UNIVERSITY LIBRARY

of interest. Detection may be carried out at 280 or 254 nm to trace proteins containing aromatic amino acids, or at lower wavelength (e.g., 214 or 206 nm) to measure absorption by peptide bonds. Other parts of a protein fractionation system that might be of use include a fraction collector (although in the simplest case it is possible to collect the fraction of interest by using a switch valve) and a chromatography controller, which permits automatic fractionation of the protein of interest.

Evaluate column

5. Chromatograph a colored marker (2 mg/ml Blue Dextran 2000 or 0.2 mg/ml vitamin B_{12}; see Basic Protocol 1, steps 20 to 23) and ascertain that the zone produced is horizontal and sharp.

   A volume of marker solution 1% to 4% of the bed volume should be applied. The zone produced by a colored sample must be horizontal and sharp for packing to be considered acceptable.

   If the supplier recommends a different method than this for evaluating column packing, that method should ordinarily be used.

6. Chromatograph a low-molecular-weight marker (e.g, 5 mg/ml acetone or 2 M sodium chloride; see Basic Protocol 1, steps 20 to 23) and construct a chromatogram to determine the column efficiency.

   The sample volume applied in this step may contribute considerably to the peak width and result in a falsely low value for column efficiency. It is therefore recommended that the sample volume not exceed 0.9%, 0.5%, and 0.4% of the bed volume for columns packed with GF matrices having average particle diameter of 100 μm, 30 μm, and 10 μm respectively (Hagel, 1985).

7. Calculate the number of theoretical plates per column according to the equation $N = 5.54(V_r/W_h)^2$, where N = number of theoretical plates per column, V_r = elution (retention) volume of peak, and W_h = width of the peak at half peak height. See Figure 8.3.2 for a graphical depiction of these variables.

   The efficiency of the column corresponds to the number of theoretical plates under given experimental conditions. See UNIT 8.1 for discussion of column efficacy.

8. Calculate the asymmetry factor of the peak according to the equation $A_s = (b/a)$, where a is the width of the leading part of the peak and b is the width of the tailing part of the peak at 10% peak height.

9. Compare the plate number and asymmetry factor obtained for the column with the acceptance limits for these parameters in the manufacturer's documentation.

   If no data for expected column performance is given, calculate the plate height (H) according to the equation $H = L/N$, where L is the length of the packed bed and N is the number of theoretical plates calculated in step 7. As a rule of thumb, H should be about three times the average particle diameter of the matrix for a good column and twice the average particle diameter for an excellent column. Plate heights of five times the average particle diameter or more are generally not accepted for high-resolution chromatography. The asymmetry factor should be 1.0 ± 0.2.

   The flow rate used will influence the broadening of the solute peak; suggested flow rates for GF matrices of different particle size are given in Table 8.3.7.

Perform chromatography and evaluate results

10. Dissolve, apply, and chromatograph protein sample to be fractionated (see Basic Protocol 1, steps 20 to 23).

    Start by applying a small fraction of the sample to get a rough idea of the separation and to calculate optimum conditions for the actual run. A sample volume of ~1% to 4% of the bed volume has been found to be optimal for protein fractionation using a medium of 30-μm

BOCA RATON CENTRAL UNIVERSITY LIBRARY

particle size, depending upon the processing rate (i.e., amount of substance processed per unit time) of the system (Hagel et al., 1989). As a general rule, a sample volume of 2% of the bed volume can be applied. A chromatogram illustrating protein fractionation where dimers and higher aggregates are separated from the target monomeric form of the protein is given in Figure 8.3.4.

Optimum sample volume depends upon many experimental factors; discussion of optimization strategies have been published (Hagel et al., 1989; Hagel and Janson, 1992). In general, the larger the bead size used, the larger the sample volume that may be applied before the initial resolution is lost. This is due to the fact that smaller bead sizes normally result in more efficient columns that produce narrower peaks; hence the influence of sample volume on peak width is more detrimental.

Table 8.3.7 Practical Velocities for Protein Fractionation or Size Determination[a]

Solute molecular mass	Nominal eluant velocities (cm/hr) at a support particle size of (μm):						
	2	5	10	15	30	50	100
1,000	507	203	101	68	34	20	10
5,000	293	117	59	39	20	12	6
10,000	234	94	47	31	16	9	5
15,000	195	78	39	26	13	8	4
50,000	137	55	27	18	9	6	3
75,000	121	48	24	16	8	5	2
100,000	109	44	22	15	7	4	2
200,000	86	34	17	11	6	3	2
300,000	76	30	15	10	5	3	2

11. Check the purity of the collected fraction(s).

Suitable methods of determining purity include HPLC and electrophoresis (see UNITS 10.1-10.4).

DETERMINATION OF MOLECULAR SIZE

BASIC PROTOCOL 3

The third important application of gel filtration is in determining molecular size. To accomplish this, a GF column is calibrated with reference samples of known molecular size (see Support Protocol). Gel filtration is then carried out on an unknown protein solute as in Basic Protocols 1 and 2, and the molecular size of that solute is then inferred from the calibration curve, which relates elution volumes or distribution coefficients on the calibrated column to the molecular sizes of the different reference samples. If the relationship between the molecular size and mass is known, the mass of the solute may be calculated. However, because the shapes of biological molecules vary considerably (e.g., proteins may be spherical or ellipsoidal, or in some cases more or less rod-shaped), the calculation of molecular mass (M_r) from elution volume must be done with great care. If the shape of the molecule under study is not known, the experiment will yield only its estimated solvated size. The influence of solute shape on size may be exemplified by the fact that the radius of gyration (one estimate of size) is proportional to $M_r^{1/3}$ for spherical molecules (e.g., some proteins), to $M_r^{1/2}$ for molecules shaped like flexible coils (e.g., dextrans and denatured proteins), and to M_r for rod-shaped molecules (e.g., fibrous proteins and DNA fragments of intermediate length). Thus, gel filtration is very suitable for estimating the molecular size but generally not the molecular mass of unknown solutes.

Materials

GF matrix or prepacked GF column (see Table 8.3.4 and Table 8.3.6; see Strategic Planning; see Critical Parameters)
GF fractionation buffer (see recipe; note variations for size determination)
GF chromatography column (Table 8.3.5)
High-precision pump
Protein sample for size determination

1. Prepare gel, pack column, then assemble and test GF system (see Basic Protocol 1, steps 1 to 16) using GF fractionation buffer wherever GF buffer is indicated.

For high-precision analytical gel filtration, the temperature of the chromatographic bed is often kept constant by using a jacketed column and circulating water from a temperature-controlled water bath. This makes the instrument setup more complicated, and the need for this precaution must be assessed on a case-by-case basis (e.g., if the column is calibrated at every other run, as is possible with high-speed gel filtration, there is little need for temperature control).

A high-precision pump must be used to ensure accurate and constant flow rate, which is of utmost importance for achieving reliable results in molecular size determinations. In addition to a UV detector for determining protein concentration, a detector for viscosity and/or light scattering—e.g., one employing multiple-angle laser light scattering (MALLS)—may be used for assay of molecular size or (indirectly) molecular mass. A mass spectrometry detector—e.g., one employing electrospray ionization mass spectrometry (ESI-MS)—may be used for assay of molecular mass.

If denatured standards are to be used in the calibration to eliminate the influence of molecular shape (see Support Protocol), 6 M guanidine hydrochloride (see recipe for GF buffers in Reagents and Solutions) is used as the GF fractionation buffer in this and subsequent steps.

Once a column has been calibrated (see Support Protocol), it is important to check column performance by determining the elution volume of one of the reference samples used for calibration as part of the routine testing of the system.

BCH MAIN CENTRAL UNIVERSITY LIBRARY

2. Determine the void volume (V_o) and the total liquid volume (V_t) for the system (see Basic Protocol 1, steps 17 and 18).

3. Calibrate column (see Support Protocol). Check flow rate during calibration by sampling effluent and weighing fractions.

   Calibration of the column (and chromatography of the sample) may be carried out under denaturing conditions to eliminate the effects of molecular shape. Variations in procedure are described in the Support Protocol.

   There are no general restrictions on the flow rate as long as the protein of interest separates from contaminating solutes (ideally, baseline separation should be achieved). A high flow rate will not influence the qualitative information sought—i.e., the position of the peak maximum. Thus, qualitative information may be obtained by very fast gel filtration; however, at high flow rates the danger of shear effects on elongated solutes must be considered. If a high-precision pump is used, there is less need to check the flow rate for every run (though in the author's experience this is a good practice because any pump may malfunction). If constant flow rate can be taken for granted, time may be substituted for volume in the calculations.

   For both the calibration (see Support Protocol) and the run to determine molecular size of the unknown sample, the elution volume should generally be corrected for the contribution from the sample volume (see Basic Protocol 1, step 23a). However, if the sample volume is kept constant throughout the entire investigation it may arbitrarily be regarded as a part of the dead volume of the system, and no correction is necessary.

4. Apply, elute, and chromatograph unknown sample (see Basic Protocol 1, steps 20 to 23). Prepare a chromatogram and calculate elution volume. Check flow rate by sampling the effluent and weighing fractions.

   The same applied sample volume should be used for the unknown sample as for the size standards (see Support Protocol).

   If denatured standards were used in the calibration to eliminate the effects of molecular shape (see Support Protocol), the sample must be denatured. Elution is then carried out using 6 M guanidine hydrochloride as the GF buffer.

   Often the calculations are performed on a time basis using an integrator or chromatography software (Amersham Pharmacia Biotech).

5. Calculate molecular size of unknown sample components using the calibration graph constructed in performing the support protocol.

   If two different detectors were used for the reference standards and the sample (e.g., a refractive index detector for calibration with dextran standards and a UV detector for the protein sample), a correction factor for the difference in volume between the two detectors must be used in the calculations.

   The estimate of molecular size will be correct only if there are no sample-matrix or sample-sample interactions (in fact, gel filtration has been used to study these self-association processes). The size estimate will be an apparent gel-filtration size which, together with data about the molecular mass (e.g., from mass spectrometry), will yield information about molecular shape.

6. Continue to run GF buffer through column until the next run is to be made.

   It is important to continue flushing the column to maintain column characteristics and avoid the need for recalibration (see Critical Parameters). If the next run is not to be made for a long time, the flow rate may be reduced and buffer recirculated through a filter to the buffer reservoir (see Critical Parameters). Before reusing the column after a long period of rest, the validity of the calibration curve should be checked by running two or three reference samples covering the range of interest and calculating their molecular size from the old calibration curve. The apparent size should agree with the assigned size within ±5% error.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

COLUMN CALIBRATION

Molecular size standards for column calibration should ideally be of the same shape and type as the molecules under study (e.g., globular proteins, fibrous proteins, or peptides). In cases where this requirement cannot be met, the column can be calibrated with other suitable reference substances of known size (e.g., dextrans). An apparent size may thus be assigned to the unknown and the actual size then inferred from the relationship between the shape of the different molecules. It is thus possible to use dextran as a reference for the estimation of Stokes radius for globular proteins (Hagel, 1993). However, a general shape parameter governing separation of all types of molecules by gel filtration has not yet been found (Dubin et al., 1990).

When protein standards are used, the calibration curve will reflect small natural variations in the molecular shapes of proteins, which will decrease the precision of the curve. However, the procedure described here is very simple and will readily yield an apparent molecular mass or molecular weight, which in many cases is quite satisfactory.

The influence of protein shape on the calibration curve may be eliminated by disruption of noncovalent bonds with denaturing solvents (e.g., guanidine hydrochloride). Disulfide bonds are broken by reductive cleavage with a reagent such as DTT, and reoxidation is prevented by carboxymethylation. This treatment converts the shape of sample and reference proteins to random coils. The physical size of a random coil is larger than that of a compact molecule of equal mass; therefore a more porous gel is needed to separate the former species. Detergents may also be used to denature proteins. However, it must be noted that a protein-detergent complex is larger than the protein and that ionic detergents will introduce charged groups. Also, information about size or molecular mass obtained using detergent-denatured proteins may not be relevant to the native protein. As these types of treatment are frequently used to prepare proteins for analytical electrophoresis, the reader is referred to *UNITS 10.1-10.4* for further details.

The influence of variation in shape on the calibration curve may also be eliminated by using as molecular size standards reference substances from a homologous class of nonprotein polymers—e.g., dextran or polyethylene glycol. Dextran has been used extensively as reference substance for calibration of gel-filtration columns. Calibration can be done by running a number of narrow fractions or one sample of broad size distribution.

***Additional Materials** (also see Basic Protocol 3)*

Calibration standards (see recipe and Table 8.3.8)
6 M guanidine hydrochloride (*APPENDIX 3A*)
In-line refractive-index detector

For calibration with native proteins

1a. Calibrate the column using protein standards (see Table 8.3.8) as in steps 20 to 23 of Basic Protocol 1 and construct a chromatogram.

It is practical to mix a number of the calibration standards and chromatograph them simultaneously so that the calibration may be completed in a few runs (see example in Figure 8.3.5).

2a. Plot the elution volume (V_r; i.e., the volume on the chromatogram from the injection point to the apex of the peak for a particular size standard) versus the logarithm of the molecular size, $\log_{10}R$, where R is the molecular radius of the calibration standard.

Table 8.3.8 gives the molecular radii of commonly used calibration standards. A sigmoid curve should be obtained that is approximated by a straight line in the middle section (see Fig. 8.3.5).

BCU IMS / CENTRAL UNIVERSITY LIBRARY

If the sample volumes are not held constant, the elution volume must be normalized by setting the injection point at half injected volume.

The calibration curve is often made system-independent by plotting distribution coefficient (K_D) versus $\log_{10}R$. The distribution coefficient is calculated as

$$K_D = (V_r - V_o)/(V_t - V_o),$$

where V_r is the elution volume for a particular peak, V_o is the void volume for the column, and V_t is the total liquid volume for the column.

For substances belonging to a homologous series (e.g., dextrans), it is meaningful to plot elution volume versus the logarithm of the molecular mass ($\log_{10}M_r$). Where substances of different chemical nature are being used to calibrate the column, the preferable way to

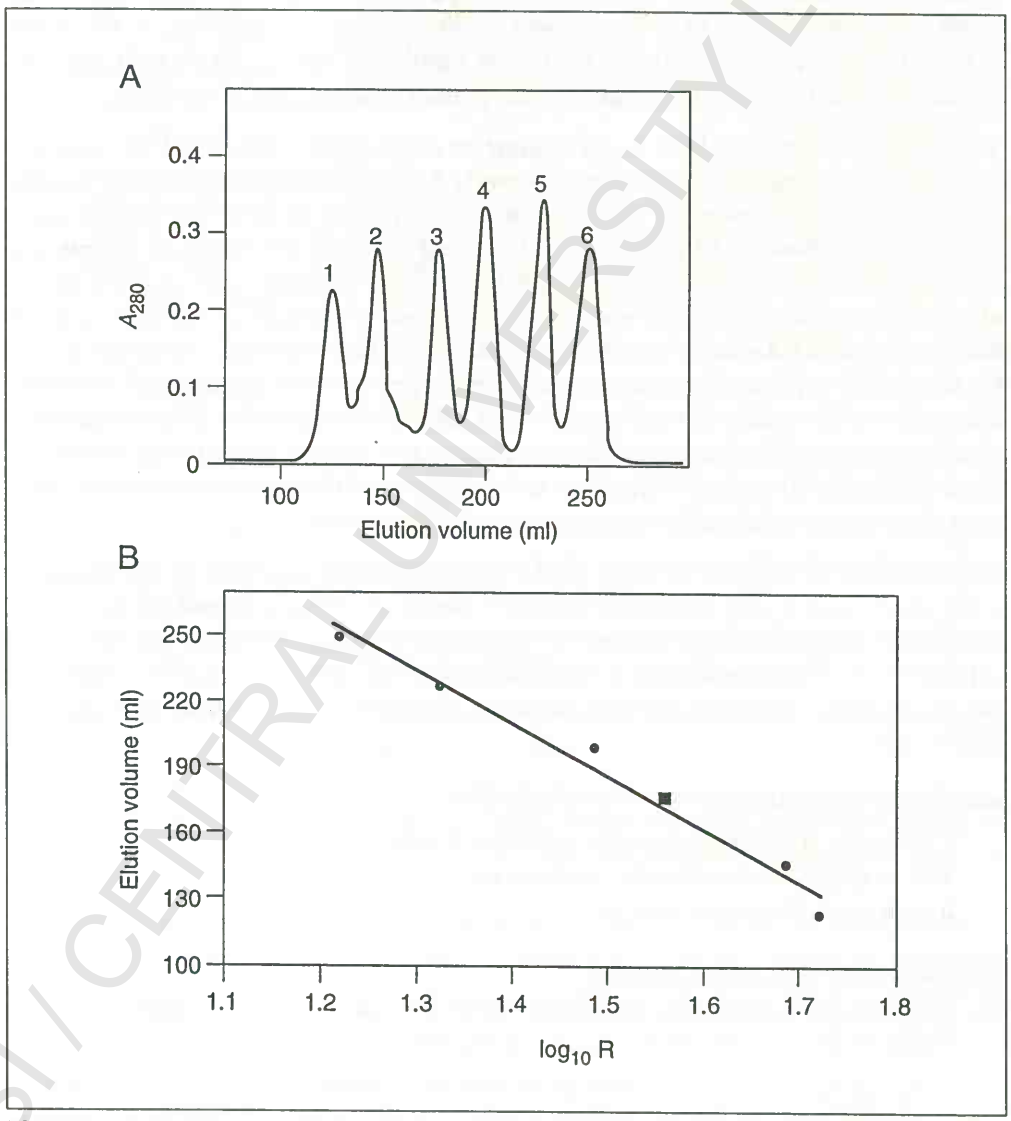

Figure 8.3.5 Calibration of GF column for determination of protein size. A K 26/70 column packed with Sephadex G-200 SF is used. **(A)** Chromatogram obtained for six size standards: 1, catalase; 2, aldolase; 3, bovine serum albumin; 4, ovalbumin; 5, chymotrypsinogen A; 6, ribonuclease A. **(B)** Calibration curve obtained by plotting the logarithms of the molecular radii ($\log_{10}$R) of the standards (*x* axis) versus the elution volumes for peaks 1, 2, 4, 5, and 6 from panel A (filled circles). The curve was used for evaluating the size of bovine serum albumin (filled square; elution volume corresponds to peak 3 in panel A), giving an apparent size of 34.8 Å. The excellent agreement with the nominal molecular size value of 35.5 Å may be incidental. Repeating the procedure for peak 4 in panel A showed that a deviation of ~3 Å from the nominal value may be expected for proteins of globular shape. Panel A reproduced from Pharmacia Biotech (1991) with permission from the publisher.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

calibrate the column is by using the hydrodynamic volume, V_h. This is calculated according to the equation $V_h = (\eta)(M_r)/N\nu$, where η is the intrinsic viscosity, M_r is the relative molecular mass, N is Avogadro's number (6.02×10^{23} molecules per mole), and ν is a shape factor, which for a spherical solute is 2.5.

It is wise to check the accuracy of the calibration by deleting one point at a time from the calibration data set and calculating the size or mass of the protein represented by that point from the calibration curve obtained with the remaining data. The average absolute difference from the nominal value indicates the accuracy of the calibration (see Fig. 8.3.5).

For calibration with denatured standards

1b. Denature calibration standards according to a standard denaturing protocol.

2b. Carry out steps 1a and 2a above, using a column equilibrated in 6 M guanidine hydrochloride and using 6 M guanidine hydrochloride as the GF buffer in the cross-referenced steps of Basic Protocol 1.

Where denatured standards are used, denaturing conditions must be maintained in chromatography of the sample (see Basic Protocol 3).

For calibration with nonprotein polymer standards

1c. Using an in-line refractive index detector, run system until a stable baseline is obtained. Chromatograph a number of dextran calibration standards (see Basic Protocol 1, steps 20 to 23) that will give calibration points surrounding the protein under study, to obtain their elution volumes or distribution coefficients.

The proper number and size of calibration standards to be run may be quickly found by running first the unknown sample and then the necessary calibration samples that will be eluted close to the unknown protein.

Apply each standard individually or as a mixture of two dextrans of high and low molecular mass.

Using a two-channel recorder set at two different sensitivities may prevent the peak from running off scale.

2c. Plot the elution volume (V_r) or distribution coefficient (K_D) versus the logarithm of the viscosity radius of dextran ($\log_{10} R_{vis}$).

The viscosity radius of dextran, R_{vis}, is related to the molecular mass (M) according to the equation $R_{vis} = 0.271 \times M^{0.498}$. Because dextran is a polydisperse polymer, the value of M used here is the molecular mass of dextran that corresponds to the peak apex, sometimes denoted M_p.

When two different detectors are used for calibration and chromatography of the sample—e.g., a refractive index detector for dextran standards and a UV detector for the protein sample—the difference in volume between the two detectors must be taken into account in calculation of elution volume.

Another procedure where the entire separation range of interest was calibrated in one run, using an integral calibration method, has been described (Hagel and Andersson, 1991; Hagel, 1993). Unfortunately, this simple and powerful method cannot yet be performed on routine basis because it requires data for the molecular mass distribution of the sample, and this information is, at the moment, not readily available in most cases.

REAGENTS AND SOLUTIONS

Use Milli-Q-purified water or equivalent for the preparation of all buffers. For common stock solutions, see ***APPENDIX 2E****; for suppliers, see* ***SUPPLIERS APPENDIX****.*

Calibration standards

Table 8.3.8 provides a compilation of commercially available molecular size calibration standards and their suppliers. Some of these are available as kits (e.g., from Amersham Pharmacia Biotech). Protein standards should be prepared in the GF buffer that will be used in the molecular size determination. To prolong the life of the column, samples should be filtered through a protein-compatible filter prior to injection. The exact concentration to be prepared depends on the additives present (e.g., sucrose as stabilizer), detector sensitivity, and the zone broadening of the column. Concentrations of proteins in the range from 1 to 5 mg/ml are frequently used for calibration. It is possible to mix several standards to calibrate the separation range of interest in a few runs (it is seldom necessary to calibrate the entire separation range of the column).

Table 8.3.8 also lists some dextran fractions that are useful for calibrating the column in hydrodynamic volume, which makes comparing solutes of different shape easier.

GF buffers

For desalting: Use a volatile buffer—e.g., 0.05 M ammonium hydroxide, 0.05 M acetic acid, 0.05 M ammonium acetate, or 0.5 M ammonium bicarbonate—unless the step is for buffer exchange, in which case use the desired final buffer.

Distilled (Milli-Q-purified or equivalent) water may be preferred to buffer as an eluant in some cases. This will yield adequate results with noncharged solutes; however, ionic interactions with the small amount of charged groups on the gel surface may disturb the purification of slightly charged molecules when water alone is used. Addition of a volatile bacteriostatic agent—e.g., chlorhexidine—may sometimes provide enough ionic strength to suppress such interactions.

For protein fractionation: Use 0.05 M sodium or potassium phosphate (pK_a = 2.1, 7.2, 12.4), 0.05 M Tris·Cl (pK_a = 8.1), or 0.05 M sodium or potassium acetate (pK_a = 4.8).

The buffering capacity of these buffers is adequate at a pH within ±0.5 units of the pK_a value. If the protein is to be freeze-dried, use of a volatile buffer or water is advantageous.

It is sometimes necessary to add 0.1 M sodium chloride to completely eliminate ionic interactions. If parts of the system that come into contact with the buffer are composed of steel, the sodium chloride should be replaced with 0.05 M sodium sulfate to prevent halide-induced corrosion. In some cases the ionic strength of the buffer will affect the sample, e.g., by disrupting aggregates. This effect can be eliminated only by changing the ionic strength.

For determining molecular size: Use the same buffers as for protein fractionation but select one that will preclude solute-matrix interactions (see Support Protocol). If the column is to be used for a long period, add preservatives to prevent bacterial growth. Make sure the buffer is compatible with the detection step (e.g., use a buffer with low salt content if mass spectrometry will be used for detection).

If calibration is to be conducted under denaturing conditions, 6 M guanidine hydrochloride is used as the GF buffer. Guanidine hydrochloride (APPENDIX 3A) is a better denaturing agent than urea.

For all buffers: Add antimicrobial agent if buffer will be used for a long time, adjust the pH of the buffer, filter through a 0.22-µm filter, then recheck pH and readjust if necessary.

It is also recommended to degas the buffer prior to prolonged use. It is common practice to prepare fresh buffer once a week, but if an antimicrobial agent has been added it may be

continued

BCU IASI / CENTRAL UNIVERSITY LIBRARY

stored for 1 month or more. Antimicrobial agents used for GF buffers include ethanol added to a concentration of 20% (v/v), sodium azide added to a concentration of 0.02% to 0.05% (w/v), or chlorhexidine added to a concentration of 0.002% (w/v). Ethanol is not recommended for use with Sephadex gels as organic solvents cause the bed to shrink when used with this matrix.

IMPORTANT NOTE: Sodium azide is a very potent antimicrobial agent and therefore widely used. However, handling of azide, especially the dry powder, requires special attention; please refer to information from the supplier for safety precautions. Frequent exposure to the dry powder may be avoided by preparing a stock solution (e.g., 20% w/v) from which aliquots (e.g., 1 ml azide stock solution to 1 liter GF buffer) may be drawn conveniently with a micropipet. Azide may form explosive salts in lead-pipe waste disposal systems; collect the effluent in waste bottles.

Total liquid volume marker

5 mg/ml acetone, 10 mg/ml sodium azide, 0.1 mg/ml cytidine, 10 mg/ml sodium nitrate, and 2 M sodium chloride have been used for determination of total volume. A negative pulse from injection of water can also be used. In cases where interactions between matrix and solute must be eliminated, deuterium oxide can be used.

Acetone and cytidine are detected by UV absorbance at 280 nm, azide at 254 nm, and nitrate at 254 nm. Sodium chloride can be detected by flame photometry, conductivity, a sodium or chloride electrode, or precipitation of chloride with silver nitrate solution. A negative pulse from injection of water is detected by measuring the absorbance or refractive index of the buffer or by monitoring the conductivity of the effluent. Deuterium oxide is detected with a refractive-index detector.

Void marker

A suitable substance for determining void volume is a protein of the correct size (not too large and not too small), which may be selected by running a series of large proteins and observing which of them start to permeate the matrix. Other substances that have been used include 2 mg/ml Blue Dextran 2000 and DNA.

Blue Dextran 2000 has the advantage of being visible to the eye. Disadvantages are that small amounts of free dye may stick to the gel and a broad permeating peak may be visible in addition to the sharp excluded peak if the pore size of the gel is large enough (e.g., as with Sepharose 4B). This occurs because of the polydispersity of dextran. If the molecule is too large, so-called secondary exclusion effects, in which the sample is excluded from the narrow space where beads intersect, will yield a falsely low void volume. However, this phenomenon is only important in high-precision gel filtration and rarely has to be considered in desalting.

COMMENTARY

Background Information

Although separation of molecules according to size had been noticed in the mid-1950s (Lindqvist and Storgårds, 1955; Lathe and Ruthven, 1956), the discovery of gel filtration (GF) may be attributed to Porath and Flodin (1959), who realized the potential of the technique and were the first to report using it to desalt proteins. Their discovery provided the basis for a new separation technology that rapidly gained widespread acceptance owing to the commercial availability of a suitable cross-linked gel-filtration matrix—Sephadex—introduced in 1959. Remarkably enough, after 35 years this matrix is still one of the premier choices for desalting of proteins (see Table 8.3.1). The use of gel filtration for determination of molecular size of proteins was described later (Andrews, 1970). Gel filtration was also rapidly established as an important tool for determining the molecular mass distribution of polymers in aqueous (Granath and Flodin, 1961) and organic solutions (Moore, 1964), for which suitable methods were lacking at that time. Moore used cross-linked polystyrene-based media for his application, naming the technique gel-permeation chromatography. Thus, within a few years after the discovery of gel filtration, applications of the technique basically covered the present range.

During the following years, the focus was directed to investigating the mechanism behind gel filtration. Theories suggesting that the separation was regulated exclusively by diffusion

POSTGRADUATE MEDICAL CENTRE UNIVERSITY LIBRARY

of molecules were soon replaced by the explanation, accepted today, that the process is driven by loss of conformational entropy when free permeation of the matrix by a solute is hindered by steric factors (Casassa, 1967). Of course, diffusion affects peak width and thus also the degree of separation, but diffusion does not influence the elution volume of a solute. The definite impact of steric exclusion on the separation has led to the proposal to rename the technique "steric exclusion chromatography" (ASTM, 1978), but this term has not gained wide acceptance. Another generic designation sometimes used in the literature is size-exclusion chromatography (SEC). It is important to realize that all of these designations refer to the same basic separation principle, which the majority of protein chemists refer to as gel filtration.

Development of gel-filtration media was focused for a long period on natural polymers or hydrophilic polymers. The late 1970s saw the introduction of silica-based materials, which combined rigidity and small particle size to enable fast gel filtration. A few years later, natural polymers of enhanced rigidity were

[b]The size of proteins may vary according to the source of information and the methodology used for determination—e.g., a value of 67.1 Å has also been assigned to ferritin (de Haen, 1987).

[c]Dextran is a polydisperse polymer and values given here—e.g., peak molecular mass—may vary from lot to lot. In cases where peak molecular mass is not stated by the supplier, the column is calibrated as elution volume versus $M = (M_w \cdot M_n)^{1/2}$, where M_w is the weight-average molecular mass and M_n is the average molecular mass. The molecular size of dextran is calculated according to the equation $R_{vis} = 0.271 \times M^{0.498}$, where R_{vis} is the viscosity radius and M is the molecular mass (Hagel, 1989).

RCU IASI CENTRAL UNIVERSITY LIBRARY

introduced, which made it possible to pack columns with matrices of 10-μm bead size. To distinguish these media from the traditional type, the designation of high-performance size-exclusion chromatography (HPSEC) was introduced. However, it has been recently pointed out that the advantage of HPSEC media lies not in performance (i.e., traditional media packed in long columns may have equal or even better resolving capacity) but in speed of operation (Hagel, 1992). In addition, none of these materials have the outstanding selectivity shown by some of the traditional matrices (e.g., Sephadex and Bio-Gel P). Therefore, development of matrices for gel filtration has now been directed toward increasing their selectivity, which is done by decreasing the apparent width of the pore-size distribution of the matrix. Development is also geared toward tailoring the apparent pore size of matrices for the separation of molecules in specific interesting areas of application (e.g., for polishing of recombinant peptides). Recently, some of these modern media have become available for separation of peptides and proteins of moderate size (Hagel, 1993).

Even though the theoretical framework for the separation mechanism in gel filtration is well understood, there are still some uncertainties as to which molecular size estimate the elution volume reflects (Dubin et al., 1990). It is generally agreed that Stokes radius is a poor measure of molecular size, especially if different types of molecules are being studied. The hydrodynamic volume seems to be a general size parameter for polymers, globular proteins, and DNA of a certain length (Potschka, 1987). It appears that more work needs to be done to resolve this fundamental issue.

Until recently, development of instrumentation for gel filtration has been modest. High-precision pumps and automated systems for injection, fraction collection, and calculation were introduced more than a decade ago. New equipment and technology being introduced includes multiple-angle laser light scattering (MALLS) detectors and in-line viscosity detectors, which provide information about the shape and size of molecules, and electrospray ionization mass spectrometry (ESI-MS), which has the power to provide in-line detection of molecular mass. ESI-MS combined with high-resolution gel-filtration columns provides a very powerful system for characterizing protein dimensions. Molecular size of solutes may also be determined with an in-line light-scattering or viscosity detector combined with a concentration-sensitive detector. It is now possible to obtain the exact molecular mass of small-to-medium-sized proteins by connecting an in-line mass spectrometer to the GF column. The advantages of using a mass-sensitive detector are that the system does not need to be calibrated, fluctuations in flow rate are not detrimental, and solute-matrix interactions or solute-solute interactions will not affect the molecular mass obtained. In this case, the column acts as a high-resolution separating device to resolve the sample components prior to determination of molecular mass by mass spectrometry.

Critical Parameters

Optimization and scaleup of desalting

Optimization of desalting starts with selection of a matrix of suitable exclusion limit with maximum pore volume and proper particle size. The bed volume is dictated by the sample volume to be purified. The actual elution protocol to be used depends upon the dispersion of the chromatography system, which in turn is related to the particle size and the column length. The particle size will influence the pressure drop over the column; this may be a limiting factor determining the maximum possible flow rate, the maximum column length, and the possibility of scaling up to columns of large diameters (i.e., the pressure specification is often reduced for columns of large diameter). However, in this case the column length can be traded off for an increase in column diameter to keep the bed volume high (also see Strategic Planning, Selecting Matrix and Column for Desalting).

To maximize the sample volume that can be applied to a column

A gel matrix should be selected from which the protein is excluded (see Strategic Planning) and in which the contaminants are eluted close to the total liquid volume (see Basic Protocol 1). It should also have a small matrix volume.

The maximum sample volume that can be applied to a column is directly related to the pore volume of the packed bed (V_i). The pore volume is proportional to the geometric column volume. As a rule of thumb, the maximum sample volume that may be applied for desalting is 25% to 40% of the bed volume for the materials listed in Table 8.3.1. The lower figure applies to small columns (e.g., <10-ml bed volume) and the higher figure to large columns (e.g., 100-ml bed volume). After the bed length

BOSTON UNIVERSITY LIBRARY

is determined on basis of the acceptable pressure drop (which is proportional to the bed length), the sample capacity is maximized by increasing the diameter of the column. This is done because the applicable volume is directly proportional to the cross-sectional area of the column. Limitations in applicable column length may be eliminated by using columns in series ("stacked columns").

The maximum volume that theoretically can be applied for desalting is equal to the separating volume of the system, which is calculated by subtracting the void volume from the total volume (see Basic Protocol 1 for steps to determine these quantities). To account for extra zone-broadening effects, it is generally advisable to apply not more than 80% of the separating volume or even less—e.g., 50%—for small columns in which eddy dispersion (see discussion below) will contribute proportionally more to the zone broadening.

To optimize the yield of desalting

Sampling of the protein fraction must be adjusted according to the zone broadening of the sample (i.e., the width of the protein zone). For a well-packed column with a plate height (see Basic Protocol 2) roughly equal to two particle diameters, this parameter may be estimated as the sample volume plus the dispersion of the zone that occurs through different pathways in the packed bed—i.e., eddy dispersion. The peak width (w_b) is described by Equation 8.3.1:

$$w_b = 4(V_t)\left(\frac{2d_p}{L}\right)^{\frac{1}{2}}$$

Equation 8.3.1

where V_t is the total liquid volume of the column, d_p is the particle size of the matrix, and L is the length of the packed bed. Thus, for a 5-ml NAP-5 column (0.9 × 2.8–cm bed dimensions) packed with Sephadex G-25 medium-particle matrix (particle size 175 µm), eddy dispersion adds ~0.6 ml to the sample volume. This is roughly equal to the maximum sample volume (i.e., the separation volume; see Basic Protocol 1) and thus the eluted fraction is twice the sample volume. However, for a much larger 4 × 85–cm column packed with Sephadex G-25 coarse-particle matrix, which has an estimated particle size of 300 µm, the eddy dispersion adds ~100 ml to the originally applied sample volume of 400 ml, giving a protein zone of 500 ml (see Fig. 8.3.3). If G-25 medium-particle matrix were used, the smaller particle size would in this case theoretically decrease the protein zone from 500 to 475 ml, at the expense of a pressure drop over the column three times higher than with the coarser medium.

To minimize the time of the separation

Use the highest possible flow rate for the desalting step. High flow rates are suitable for desalting because eddy dispersion effects are rather insensitive to flow rate. The limiting factors on the flow rate are the rigidity of the matrix and the pressure limitations of the system used. Because media with small pore volume are generally more rigid than those with large pore volume, the disadvantage of a smaller separating volume may be offset by increasing the applicable flow rate to keep productivity high when working with the former type of medium. Incomplete removal of fine particles from the medium prior to packing may reduce the flow rate of the column after use as a result of partial blockage of the outlet filter. Operating the column with the flow direction reversed may help to increase the applicable flow rate in such situations.

The total process time for repetitive runs to desalt large volumes may be further minimized by utilizing the dead time of the void fraction. To do this, samples are added, not after total liquid volume + sample volume + eddy dispersion volume, but after subtracting the void volume from the total process volume (i.e., the next sample is added before the salt peak of the previous sample has emerged). The saving in time may be in the range of 20% to 30%, but this practice can only be recommended for well-understood processes.

Optimization and scaleup of protein fractionation

There are two basic ways to optimize the resolution of a separation. One is to increase the peak-to-peak distance and the other is to decrease the peak widths. The resolution for gel filtration is described by Equation 8.3.2:

$$R_s = \frac{1}{4}\log_{10}\left(\frac{M_{r1}}{M_{r2}}\right)b\left[\frac{1}{\left(\frac{V_o}{V_i} + K_D\right)}\right]\left(\frac{L}{H}\right)^{\frac{1}{2}}$$

Equation 8.3.2

where M_{r1} and M_{r2} are the molecular masses of the two sample components being separated, b is the slope of the selectivity curve

BCU IASH CENTRAL UNIVERSITY LIBRARY

($-\partial K_D/\partial \log M_r$), V_o is the void volume of the column, V_i is the pore volume of the bed, L the bed height, and H the plate height of the column (i.e., the term $L/H = N$, the plate number). The impact of these parameters will be described below.

To increase the peak-to-peak distance

1. A matrix of high selectivity should be chosen. The most important factor for optimizing protein fractionation is selectivity, which is the inherent ability of the matrix to resolve proteins of similar size. This factor is a function of the pore-size distribution of the matrix. Selectivity is often illustrated by a plot of the elution volumes of a series of reference substances versus the logarithm of the molecular size or molecular mass of those substances. A function of the elution volume (e.g., the distribution coefficient; see Basic Protocol 3) may be substituted for the elution volume in constructing a selectivity curve. The steeper the selectivity curve (i.e., the greater the absolute value of the slope b, defined above), the better the resolvability of proteins differing in size. The selectivity of different gels can be judged from the fractionation range stated by the manufacturer. Gels with a small fractionation range (in terms of $\log M_r$) will generally have higher selectivity than gels with a large fractionation range.

2. A gel of high pore volume should be selected. The pore volume of a matrix is often related to the particle size. Smaller particles need to resist a higher friction force from the high flow rates that are used with matrices of smaller bead size; therefore the matrix volume is generally larger and pore volume smaller when using these matrices. A traditional soft-gel matrix may have up to 98% pore volume, whereas rigid matrices such as silica may have as low a pore volume as 52% (of the bead volume).

3. A column of sufficient length (L) should be selected. The resolution between peaks is proportional to the square root of the column length. The column length chosen for protein fractionation is usually optimized with respect to the particle size of the matrix—i.e., a 100-cm column is often chosen where the particle size is 100 µm, a 60-cm column where the bead size is 30 µm, and a 30-cm column where the bead size is 10 µm.

To decrease peak width

1. A material that yields a small void volume (V_o) should be selected. Reducing the void volume will decrease the dispersion of the protein band (as will minimization of all extra column dead volumes). Irregularly shaped or rigid particles generally yield beds with larger void volumes than spherical, nonrigid beads.

2. A material of small particle size should be used, as this will affect the plate height (H; also see Basic Protocol 3). Zone broadening of proteins within a column is directly proportional to the square of the particle size. Therefore, smaller particles will yield smaller peak widths unless very large sample volumes are applied or large system effects are causing dispersion of zones.

3. The separation should be run at optimum flow rate, as this will affect the plate height (see Basic Protocol 3). Zone broadening is caused by dispersion within the void volume of the chromatographic bed, or by nonequilibrium effects that occur in the separation process itself when the mobile-phase velocity in the extra-particle space is too high as compared with the diffusivities of the proteins and the diffusion distances in the matrix. Flow rates that will allow minimum zone broadening and complete equilibrium will in most cases be impractically low. Table 8.3.7 lists practical flow rates for different solute molecular weights and matrix particle sizes, which represent compromises with regard to these parameters.

Dissolving the sample

Care must be taken to assure that the sample is completely dissolved in the GF buffer. Conditions must be chosen so that spontaneously formed aggregates are dissolved and aggregates that are to be removed are not dissolved merely to reaggregate in the fraction tube. Because gel filtration permits rather free choice of pH, ionic strength, and additives, it is generally not difficult to find suitable conditions.

Solute-matrix interactions

Solute-matrix interactions are generally to be avoided. Even though mixed-mode separations (i.e., separations on the basis of both molecular size and the solute-matrix interaction) have sometimes given good resolution, one must be concerned about the reproducibility of such mechanisms. Solute-matrix interactions may be specific or nonspecific, and the chemical basis may be an ionic or hydrophobic interaction. In the case of specific solute-matrix interactions, the only thing to do is to change the matrix to one based on a different chemistry. Ionic interaction can be suppressed by addition of an electrolyte; hydrophobic interaction can

RCU RESTRICTED USE ONLY LIBRARY

be reduced by adding an organic modifier (e.g., methanol, acetonitrile, or isopropanol) or by reducing the ionic strength of the buffer. Of course, avoidance of solute-matrix interactions is a prerequisite for estimating molecular size using a calibrated column (see Basic Protocol 3 and Support Protocol). Solute-matrix interactions can be uncovered by varying the composition of the mobile phase or temperature and noting the effect. Because ideal gel filtration is driven by entropy, temperature should not affect the elution volume of proteins (unless the temperature change affects protein size or the pore size).

Column maintenance

Column life is drastically reduced by introduction of air into the column, deposition of material on the bed surface, and use of flow rates that exceed the maximum recommended flow rate. To protect valuable columns from air it is advisable to use an air trap, to degas the buffer, or to use a deaerator. Deposition of material is minimized by filtering both sample and buffer through a 0.22-μm filter prior to application. Exceeding the maximum flow rate or pressure (e.g., by failing to compensate for viscosity effects at low temperatures) will result in the bed becoming compressed. This may be avoided by using a flow or pressure sensor to shut down the pump if the limit is exceeded. To maintain the calibration of a column for molecular size determinations (see Basic Protocol 3 and Support Protocol), the flow through the column should never be turned off completely, but may be reduced (e.g., to one-tenth) and the effluent recycled to the buffer reservoir through a filter. The buffer should be treated with preservatives and must be discarded when the column is put back in service. According to the author's experience, the lifetime of a column may be expected to exceed several years and calibration may remain valid for up to 1 year if the appropriate precautions are taken.

A parameter that reflects the possibility of bed compression is the void fraction—i.e., the void volume divided by the bed volume. This parameter is 0.26 for beds made up of tetrahedral, closely packed spheres and 0.40 for beds made up of randomly packed spheres. Experimentally determined void fractions vary from 0.30 to 0.47 because of the surface and packing properties of the matrix and the particle shape. Void fractions <0.30 may indicate compression of beads.

Flow rate

Flow rate must be carefully controlled, especially if the column is used for characterization of molecular size as in Basic Protocol 3. The actual flow rate of a pump seldom agrees with the nominal flow rate, so it is essential that the flow rate be checked regularly.

Troubleshooting

Gel filtration is a comparatively uncomplicated separation technique and troubleshooting is straightforward. Provided that the critical aspects of the technique (see Critical Parameters) are kept under control, gel filtration can be expected to be relatively trouble-free. Problems that may arise most frequently are compression of the bed and consequent decrease in flow rate, air bubbles in the column, tailing or leading peaks, and peaks that elute in the "wrong place."

Bed compression and decreased flow rate

Compression of the bed most likely results from the maximum flow rate being exceeded during packing (see Critical Parameters). It may also arise from excessive packing of the column, which creates an inhomogeneously packed bed with a denser layer in the lower part of the column that will eventually collapse even at a moderate flow rate. A column found to have a compressed bed must be repacked.

Compression may also result from partial clogging of the inlet filter and the upper part of the bed. To save the column in such a case, the adaptor should be removed, the filter cleaned, contaminated upper matrix removed, the upper part of the bed swirled, and the bed restabilized (see Basic Protocol 1, step 11). If the column still does not perform as expected, it must be repacked.

Decrease in the flow rate often accompanies compression of the bed. If the gel contains fines, these may block parts of the outlet net, causing a decrease in flow rate. Reversing the direction of flow may restore normal conditions. If this is not successful, the column should be repacked after exhaustive decantation of fines (see Basic Protocol 1, steps 3a and 2b).

Air bubbles in column

Small air bubbles in the column may be due to failure to deaerate the buffer or to the introduction of bubbles during sample injection. Moving the column from a cold room directly to a warmer laboratory will also release air bubbles in the column and should be avoided.

RCU IASI LIBRARY

An attempt may be made to remove the bubbles by pumping deaerated buffer through the column in the reverse direction. Heating the buffer slightly is sometimes successful, as the temperatures of the buffer and gel will equilibrate, allowing the warmer buffer to dissolve some air. This may have to be done at least overnight and perhaps for several days to be fully successful. A large air pocket situated right under the adaptor that has not been taken up by the buffer may be removed using the procedures for readjusting the adaptor to the bed surface (see Basic Protocol 1, step 11).

Tailing and leading peaks

Tailing peaks indicate a large dead volume somewhere in the system, solute-matrix interactions, or a bed that is packed too loosely. To check the system for extra dead volumes, another column or a dummy column of small volume should be packed and a sample run to see if the problem reproduces itself. If it does not, the problem can be attributed to the column, and a sample of a different substance should then be run to ensure that the effect is not caused by solute-matrix interactions. If the tailing problem is still noted, the defect probably lies in the column packing, and an attempt should be made to stabilize the bed at a higher flow rate (see Basic Protocol 1, step 11). If this does not help, the column should be repacked at a higher flow rate. Before doing this, however, it should first be ascertained that the tailing is really seen with the sample to be run under the actual conditions under which it is to be run. Slight tailing of a small solute may be negligible when compared to a large diffusion-regulated zone broadening of a protein. Tailing may also be caused by partial separation of a small amount of a solute of slightly smaller size or slightly different surface properties.

Leading (fronting) peaks indicate solute-matrix interactions or cracks in the bed. Solute-matrix interactions (e.g., ionic-exclusion effects) are detected by running a different substance and/or using a different buffer. If the problem is related to the column packing (i.e., cracks in the bed), the column must be repacked at a lower flow rate. As with tailing peaks, however, the actual sample should first be run under the actual conditions to be used to determine whether the effect of fronting on the separation is serious. Fronting may also be caused by partial separation of a small amount of slightly larger contaminant.

Peaks that elute in the wrong place

Peaks that elute prior to the void volume indicate ionic-exclusion effects. To suppress these effects, the ionic strength of the GF buffer should be increased. Solutes that elute after the total liquid volume indicate adsorptive effects. These may be masked by adding an organic modifier or by increasing or decreasing the ionic strength of the buffer (see Critical Parameters for discussion of solute-matrix effects).

Anticipated Results

Results from gel filtration are in general very predictable. Guidelines for optimization and scaleup are presented in Hagel et al. (1989) and Hagel and Janson (1992).

Time Considerations

Gel filtration using media of small particle size may generally be carried out in half an hour. Gel filtration using traditional larger-particle matrices are typically run for 5 hr. Desalting is very fast: e.g., 1.4 ml of sample may be desalted in 30 sec.

Preparation (i.e., swelling) of the gel will take 3 hr to overnight, depending on the procedure chosen. Packing of the column takes 1 to 4 hr, and the subsequent stabilization of the packed bed takes 1 hr. Thus, a column is typically prepared in a day, and testing of the packing quality is carried out overnight.

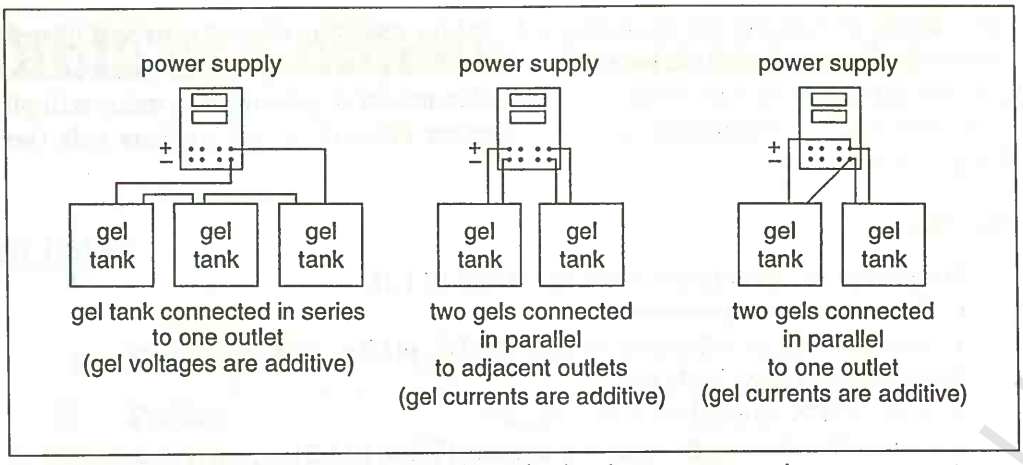

Figure 10.1.1 Series and parallel connections of gel tanks to power supply.

increase the current for each additional gel that is connected to the power supply. Two identical gels require double the current to achieve the same starting voltages and electrophoresis separation times.

Multiple gel apparatuses can also be connected to one pair of outlets on a power supply. This is useful with older power supplies that have a limited number of outlets. When connecting several gel units to one outlet, make certain the connections between the units are shielded and protected from moisture. The gels can be connected in parallel or in series (Fig. 10.1.1). In the case of two or more gels running off the same outlet in series, the current is the same for every gel. If 10 mA is displayed by the power supply meter, for example, each gel in series will experience 10 mA. The voltage, however, is additive for each gel. If one gel at a constant 10 mA produces 100 V, then two identical gels in series will produce 200 V (100 V each) and so on. Thus, the voltage can limit the number of units connected in series on low-voltage power supplies.

Gel thickness affects the above relationships. A 1.5-mm gel can be thought of as consisting of two 0.75-mm-thick gels run in parallel. Because currents are additive in parallel circuits, a 0.75-mm gel will require half the current of the 1.5-mm gel to achieve the same starting voltage and separation time. If a gel thickness is doubled, then the current must also be doubled. There are limits to the amount of current that can be applied. Thicker gels require more current, generating more heat that must be dissipated. Unless temperature control is available in the gel unit, a thick gel should be run more slowly than a thin gel.

NOTE: Milli-Q-purified water or equivalent should be used throughout the protocols.

DENATURING (SDS) DISCONTINUOUS GEL ELECTROPHORESIS: LAEMMLI GEL METHOD

BASIC PROTOCOL 1

One-dimensional gel electrophoresis under denaturing conditions (i.e., in the presence of 0.1% SDS) separates proteins based on molecular size as they move through a polyacrylamide gel matrix toward the anode. The polyacrylamide gel is cast as a separating gel (sometimes called resolving or running gel) topped by a stacking gel and secured in an electrophoresis apparatus. After sample proteins are solubilized by boiling in the presence of SDS, an aliquot of the protein solution is applied to a gel lane, and the individual proteins are separated electrophoretically. 2-Mercaptoethanol (2-ME) or dithiothreitol (DTT) is added during solubilization to reduce disulfide bonds.

This protocol is designed for a vertical slab gel with a maximum size of 0.75 mm × 14 cm × 14 cm. For thicker gels, or minigels (see Basic Protocol 2 and Support Protocol 3),

BOSTON CENTRAL UNIVERSITY LIBRARY

the volumes of stacking and separating gels and the operating current must be adjusted. Support protocols describe the preparation of ultrathin gels (see Alternate Protocol 4) and gradient gels (see Alternate Protocol 5), as well as the use of gel casters to make multiple gels, both single-concentration gels (see Support Protocol 1) and gradient gels (see Support Protocol 2).

Materials

Separating and stacking gel solutions (Table 10.1.1)
H_2O-saturated isobutyl alcohol
1× Tris·Cl/SDS, pH 8.8 (dilute 4× Tris·Cl/SDS, pH 8.8; Table 10.1.1)
Protein sample to be analyzed
2× and 1× SDS sample buffer (see recipe)
Protein molecular-weight-standards mixture (Table 10.1.2)
6× SDS sample buffer (see recipe; optional)
1× SDS electrophoresis buffer (see recipe)

Electrophoresis apparatus: Protean II 16-cm cell (Bio-Rad) or SE 600/400 16-cm unit (Hoefer Pharmacia) with clamps, glass plates, casting stand, and buffer chambers
0.75-mm spacers
0.45-µm filters (used in stock solution preparation)
25-ml Erlenmeyer side-arm flask
Vacuum pump with cold trap
0.75-mm Teflon comb with 1, 3, 5, 10, 15, or 20 teeth
25- or 100-µl syringe with flat-tipped needle
Constant-current power supply (see introduction)

Pour the separating gel

1. Assemble the glass-plate sandwich of the electrophoresis apparatus according to manufacturer's instructions using two clean glass plates and two 0.75-mm spacers.

   If needed, clean the glass plates in liquid Alconox or RBS-35 (Pierce). These aqueous-based solutions are compatible with silver and Coomassie blue staining procedures.

2. Lock the sandwich to the casting stand.

3. Prepare the separating gel solution as directed in Table 10.1.1, degassing using a rubber-stoppered 25-ml Erlenmeyer side-arm flask connected with vacuum tubing to a vacuum pump with a cold trap. After adding the specified amount of 10% ammonium persulfate and TEMED to the degassed solution, stir gently to mix.

   Table 10.1.1 was prepared as a convenient summary to aid in the preparation of separating and stacking gels. The stacking gel is the same regardless of the separating gel used.

   The desired percentage of acrylamide in the separating gel depends on the molecular size of the protein being separated. Generally, use 5% gels for SDS-denatured proteins of 60 to 200 kDa, 10% gels for SDS-denatured proteins of 16 to 70 kDa, and 15% gels for SDS-denatured proteins of 12 to 45 kDa (Table 10.1.1).

4. Using a Pasteur pipet, apply separating gel solution to the sandwich along an edge of one of the spacers until the height of the solution between the glass plates is ~11 cm.

   Use the solution immediately; otherwise it will polymerize in the flask.

   Sample volumes <10 µl do not require a stacking gel. In this case, cast the resolving gel as you normally would, but extend the resolving gel into the comb to form the well. The proteins are then separated under the same conditions as used when a stacking gel is present. Although this protocol works well with single-concentration gels, a gradient gel is recommended for maximum resolution (see Alternate Protocol 5).

Sample Preparation for MALDI Mass Analysis of Peptides and Proteins

The discovery that polar biological substances may be ejected from solid and liquid matrices as protonated or deprotonated ions by deposition of laser pulses initiated the development of methodology and instrumentation for characterization of biomacromolecules at unprecedented sensitivities. This is generally known by the acronym, MALDI-MS, for matrix-assisted laser desorption/ionization mass spectrometry (also see *UNITS 16.1 & 16.2*). The physicochemical properties of matrices that work well analytically are diverse; some matrices are suited to UV/visual laser wavelengths and others to the infrared. Although originally thought to be "soft" in terms of minimal deposition of internal energy (in the case of UV/visual laser frequencies), most modulate the vibronic activation of the analyte, giving rise to a fraction of metastable ions that are formed by unimolecular dissociation of the $[M + H]^{1+}$ or $[M - H]^{1-}$. The recorded mass spectra of these metastable ions, known as post-source decay (PSD) mass spectra, are similar to those of low-energy collision-induced dissociation (CID) fragment ions. The preponderance of ions formed are singly charged. Thus, they are well suited to high-energy collisional activation using appropriate tandem experiments to give high-energy CID-like mass spectra.

Sample preparation may be the most crucial step in mass spectrometric analysis of peptides and proteins by MALDI (also see sample preparation guidelines in *UNIT 16.2*). The free dipolar ionic peptides or proteins must be incorporated into a crystalline solid solution that is comprised of excess solvent (the matrix), which modulates desorption/ionization by preferentially absorbing the laser energy at the irradiation wavelength and laser pulse intensity being employed. Usually the cocrystalline sample and matrix are prepared by mixing solutions of each component and permitting the mixture to crystallize through evaporation of the solvents. Two methods employing this approach are presented in this unit: the dried drop method (see Basic Protocol 1) and the rapid evaporation method (see Basic Protocol 2); also see Background Information and Table 16.3.1). This process can be disturbed by the presence of contaminants such as detergents and salts (see Table 16.2.1). Matrices that are sufficiently water insoluble will permit a degree of on-target washing without dissolving and liberating the analyte. Such matrices are useful for removing some contaminants, and include α-cyano-4-hydroxy-*trans*-cinnamic acid (HCCA) and sinapinic acid. Alternatively, the water-soluble 2,5-dihydroxybenzoic acid (DHB) may be used, since this matrix excludes some impurities during crystallization.

DRIED DROPLET METHOD

BASIC PROTOCOL 1

Materials

100% methanol
Peptide or protein sample of interest: ~1 pmol/μl in 0.1% (v/v) trifluoroacetic acid (TFA)
Peptide or protein matrix solution (see recipes)
Peptide or protein standard mixture (see recipes)
Matrix-assisted laser desorption/ionization (MALDI) mass spectrometer

1. Clean the sample target with the appropriate solvents. Wipe with a Kimwipe wetted with water followed by one wetted with 100% methanol, and repeat for several cycles.

Contributed by C.R. Jiménez, L. Huang, Y. Qiu, and A.L. Burlingame
Current Protocols in Protein Science (1998) 16.3.1-16.3.6
Copyright © 1998 by John Wiley & Sons, Inc.

BOURNS / CENTRAL UNIVERSITY LIBRARY

This cleaning procedure is usually sufficient. Alternatively, wipe with 0.1% (v/v) TFA and/or sonicate the target in 100% methanol or 0.1% TFA. Detergents are not recommended as they are hard to wash away and tend to give background peaks.

2. Pipet 0.5 to 1 µl peptide or protein sample onto the target, add 0.5 to 1 µl peptide or protein matrix solution, and mix by pipetting up and down. Allow to air dry.

   Samples may also be prepared by mixing the sample and matrix solution in a microcentrifuge tube, from which 0.5 to 1 µl is applied to the target.

3. For external calibration, apply 0.5 to 1.0 µl of an appropriate peptide or protein standard mixture and 0.5 to 1.0 µl peptide or protein matrix solution (as in step 2) to the target in the vicinity of the sample.

   For highest mass accuracy, the standard solution may be mixed with an aliquot of the sample for internal calibration. However, do not add an excess of internal standard, as this may result in ion suppression of the sample. The optimal ratio of sample/standard may have to be empirically determined, although starting with equimolar amounts is recommended. In the case of peptide analysis, internal calibration may be performed on matrix ions.

4. Insert sample target into the MALDI mass spectrometer and mass analyze as recommended by the manufacturer.

   The sample target with applied matrix/sample preparations may be stored in the dark at ambient temperature for days without significant loss of signal. For longer storage, the target should be kept at –20°C in a sealed container.

   Irradiate the sample just above the threshold for appearance of the ions. Generally, the ion signals (mass-to-charge ratio, m/z) of peptides correspond to $[M + H]^{1+}$. Larger peptides and proteins yield doubly protonated ions $[M + 2H]^{2+}$ that appear at half the peptide or protein mass since m/z is being measured.

   Due to microheterogeneity of the matrix crystals, spectra should be accumulated from several different crystals of the matrix/sample preparation to obtain a representative sum spectrum. Under certain circumstances, the relative peak abundances may give a semiquantitative indication of the relative concentrations of peptides in a mixture.

BASIC PROTOCOL 2

RAPID EVAPORATION METHOD

Materials

100% methanol
Peptide matrix/nitrocellulose solution (see recipe)
Peptide sample of interest: ~1 pmol/µl in 0.1% (v/v) trifluoroacetic acid (TFA)
10% (v/v) formic acid, 0° to 4°C
Peptide standard mixture (see recipe)
Matrix-assisted laser desorption/ionization (MALDI) mass spectrometer

1. Clean the sample target with the appropriate solvents (see Basic Protocol 1, step 1).

2. Pipet ~0.5 µl peptide matrix/nitrocellulose solution on the sample target. Pipet quickly because of the high volatility of the solvent.

   The matrix/nitrocellulose solution will spread out rapidly, allowing fast evaporation of the solvent and the formation of a uniform white layer.

3. Apply ~0.5 µl peptide sample onto the matrix surface on the sample target. Allow the solvent to evaporate at ambient temperature.

   The sample solution should not completely dissolve the matrix layer. Therefore, the concentration of organic solvent in the sample should be kept <30% and the pH should be acidic. For samples with higher organic solvent concentrations or high pH, apply 0.5 µl

BCU IASI / CENTRALA UNIVERSITARA LIBRARY

water or 0.5 µl of 10% (v/v) formic acid, respectively, onto the matrix surface and then apply the sample.

4. Rinse the sample with ~10 µl cold 10% formic acid. Leave the solution on the sample for 10 sec and then remove using pressurized air, vacuum, or careful pipetting. Repeat the rinse step with water.

   This step is optional and can be omitted for samples that are free of salts (e.g., reversed-phase HPLC fractions). These rinse steps are strongly recommended for unseparated peptide digest mixtures.

5. Apply peptide standard mixture (for details on internal versus external standards, see Basic Protocol 1, step 3).

6. Insert sample target into the mass analyzer and analyze (see Basic Protocol 1, step 4).

   For best ion intensities, matrix/sample preparations made using the rapid evaporation method should be analyzed immediately.

PURIFICATION/RECRYSTALLIZATION OF HCCA

SUPPORT PROTOCOL

α-Cyano-4-hydroxy-*trans*-cinnamic acid (HCCA) matrix that has been purified often yields better sensitivities than matrix used as supplied by the manufacturer. The HCCA cleanup protocol described below was developed by B.O. Keller (Department of Chemistry, University of Alberta).

Materials

α-Cyano-4-hydroxy-*trans*-cinnamic acid (HCCA; Sigma or Aldrich)
95% (v/v) ethanol: 50°C, room temperature, and 4°C

Class C and E Whatman glass filters
50°C water bath

1. Suspend 7 to 8 g HCCA in 100 ml of 95% ethanol at room temperature. Dissolve all brownish crumbs, so that only bright yellow crystals remain undissolved.

2. Filter suspension through a class C Whatman glass filter under a vacuum. Wash the remaining crystals with 50 ml of 95% ethanol.

   The yield of undissolved HCCA is ~50%.

3. Dry the crystals and then pick out and discard any remaining black or brown crumbs in the dried residue.

4. Warm 50 ml of 95% ethanol in an Erlenmeyer flask or beaker in a 50°C water bath. To obtain a saturated solution, add dried HCCA crystals to the ethanol while swirling the flask, and continue until no more HCCA dissolves and yellow crystals remain undissolved at the bottom.

   The temperature should not exceed 50°C, as this may cause the HCCA to decompose.

5. Filter the hot (50°C) HCCA solution using a class C Whatman glass filter. Use a very clean glass flask to collect the filtrate. Cool to room temperature, cover flask, and leave at –20°C overnight.

   The next day, a precipitate of tiny crystals should be observed. If no precipitate is observed, the HCCA solution may be too dilute. Add more HCCA from step 3 to the solution in a 50°C water bath and filter again (step 4).

6. Separate the precipitate from the HCCA solution by filtration using a class E Whatman glass filter. Wash the precipitate moderately with cold (~4°C) 95% ethanol.

BCU IASI/CENTRAL UNIVERSITY LIBRARY

7. Cover the purified HCCA precipitate in the glass filter with foil. Dry 3 to 4 hr, preferably in a laminar-flow hood, and transfer to glass vials. Store below 0°C (stable for years, if repeated freezing/thawing is avoided).

REAGENTS AND SOLUTIONS

Use Milli-Q-purified water or equivalent for the preparation of all buffers. For common stock solutions, see APPENDIX 2E; for suppliers, see SUPPLIERS APPENDIX.

Peptide matrix/nitrocellulose solution

Dissolve 10 mg nitrocellulose and 40 mg/ml α-cyano-4-hydroxy-*trans*-cinnamic acid (HCCA; Sigma or Aldrich) in 1 ml acetone. If necessary, vortex 1 to 2 min to dissolve. Add 1 ml isopropanol (final 20 mg/ml HCCA and 5 mg/ml nitrocellulose in acetone/isopropanol). Prepare fresh before each use.

Peptide matrix solution

Prepare 20 mg/ml α-cyano-4-hydroxy-*trans*-cinnamic acid (HCCA; Sigma or Aldrich) either in 0.1% (v/v) trifluoroacetic acid (TFA)/50% (v/v) acetonitrile *or* in 99:1 (v/v) acetone/water (also see Support Protocol 1). Alternatively, use 20 mg/ml 2,5-dihydroxybenzoic acid (DHB) in 0.1% (v/v) TFA/30% (v/v) acetonitrile. Divide into aliquots and store at –20°C (stable for months to years).

With DHB, the percentage of acetonitrile may be varied depending on the hydrophobicity of the peptide(s) analyzed. The matrix additive 2-methoxy-5-benzoic acid may be added at 1 mg/ml to the DHB matrix solution for better detection of larger peptides (>3000 Da).

Peptide standard mixture

Prepare a mixture of peptides with known masses (e.g., bradykinin, mellitin, and ACTH) at ~1 pmol/µl in 0.1% (v/v) TFA. Divide into aliquots and store at –20° or –80°C (stable for years).

Protein matrix solution

Prepare 20 mg/ml sinapinic acid in 0.1% (v/v) trifluoroacetic acid (TFA)/50% (v/v) acetonitrile *or* in 99:1 (v/v) acetone/water. Divide into aliquots and store up at –20°C (stable for years).

Protein standard mixture

Prepare a mixture of insulin, myoglobulin, and BSA at ~1 pmol/µl (v/v) in 0.1% TFA. Divide into aliquots and store at –20°C (stable for years).

COMMENTARY

Background Information

Different on-target sample preparation methods have been developed for MALDI mass spectrometry. The most frequently used is the dried droplet method, in which the matrix is simply added to the sample on the sample stage (see Basic Protocol 1 above; see *UNIT 11.6*, Basic Protocol 3). Alternatively, a thin layer of matrix material dissolved in a rapidly evaporating solvent may be prepared on the sample target holder, onto which a solution of the analyte sample is subsequently deposited to avoid complete dissolution of the preprepared matrix film. The latter method has provided improved sensitivity and uniform desorption properties (Vorm et al., 1994). Moreover, the addition of nitrocellulose to the matrix solution may be employed to achieve better peptide binding to the target, allowing more extensive rinsing of the sample (see Basic Protocol 2; also Alternate Protocol of *UNIT 11.6*; Shevchenko et al., 1996).

Critical Parameters and Troubleshooting

The method of sample preparation as well as the matrix solvent composition can significantly affect results (Table 16.3.1) due to differential mass discrimination and ion suppression effects (Cohen and Chait, 1996). This is especially true when complex peptide mixtures

BCU IASI CENTRAL UNIVERSITY LIBRARY

are analyzed, such as unseparated protein digests. For example, in tryptic digest mixtures, the C-terminal arginine-containing components are preferentially detected. Therefore, to obtain better detection of most of the components in such a mixture, spectra should be acquired using different matrix solution conditions and different matrices.

Contaminants such as salts and detergents should be <50 mM. When crystallization is impaired due to the presence of contaminants, the matrix/sample preparation should be rinsed 1 to 3 times with ice-cold 0.1% (v/v) TFA or 10% (v/v) formic acid, and the solvent should be removed after a few seconds by pipetting or with blown pressurized air. However, hydrophilic peptides may be lost in this washing procedure, and it is not suitable for DHB matrix solutions. Alternatively, the sample can be diluted and reapplied to the target. Volatile buffers may be removed by partial drying with vacuum centrifugation. Complete lyophilization is not

Table 16.3.1 Effects of Matrix Solution Composition, pH, Presence of Detergent, and Crystallization Rate on MALDI-MS of a Complex Mixture of Peptides[a]

		Relative peptide ion intensity		
	pH	0.8-2 kDa	2-6 kDa	6-11 kDa
Composition of HCCA solution				
0.1 N HCl/ACN (2:1)	1.1	+	+++	++
1% TFA/ACN (2:1)	1.1	+	+++	++
Formic acid/water/ACN (1:3:2)	1.1	+	++	+++

Rapid		+++	+	ND

[a]Peptide mixture is a partial V8 protease digest of the 11 kDa protein Max (for details see Cohen and Chait, 1996). The dried droplet method (see Basic Protocol 1) was used for the analysis of the effect of matrix composition/pH and *N*-octyl-β-D-glucoside on MALDI-MS performance. For each matrix condition, the three mass ranges are assigned a response level: +++ designates the mass range with the highest relative ion intensities; ++ indicates moderate ion intensities; + indicates weak or no peptide ions. Abbreviations: ACN, acetonitrile; IPA, isopropyl alcohol; ND; not determined; TFA, trifluoroacetic acid.

PUJAS / CENTRAL UNIVERSITY LIBRARY

recommended because of severe sample losses. A partially lyophilized sample can be diluted with 0.1% to 5% (v/v) TFA in 20% (v/v) acetonitrile to reduce adsorptive losses and to facilitate MALDI mass analysis.

Anticipated Results

Using MALDI-MS, peptides generally yield singly protonated ions, and reasonable signal-to-noise ratios can be obtained, even in the low femtomole range. When salt is present in the sample, sodium (+22.99) and potassium (+39.10) adducts may be observed in the spectrum as well.

Mass accuracy for linear time-of-flight (TOF) mode with external calibration is typically ±2 to 3 Da for peptides <3000 Da. Reflector-TOF instruments offer improved mass accuracy with external calibration (±0.5 to 1 Da), but a 5- to 10-fold loss in signal may be observed, especially for larger peptides that are more prone to metastable fragmentation. With delayed extraction in reflectron mode, the full-width, half-maximum mass resolution (M/ΔM, FWHM) can reach >10,000 Da for analytes that have mass-to-charge ratios of 1000 to ~6000 kDa, and mass accuracies in the low parts-per-million range can be achieved at low levels of gel-separated proteins (Clauser et al., 1996 and unpub. observ.). In addition, delayed extraction provides significant improvement in MALDI spectral quality, including a lower level of chemical noise arising from fragmentation in the desorption plume, reduction or elimination of matrix background, and significant reduction in the dependence of ion flight times on laser intensity (Vestal et al., 1995). Peak width and centroids are much less dependent on the absolute intensity of the ion signal. Therefore, high mass resolution and improved mass accuracy can be achieved even when the peaks are small.

Time Considerations

One of the main advantages of MALDI-MS is its speed: MALDI sample preparation only takes a few minutes and a typical MALDI mass measurement may take less than a minute, or up to 10 min when very low amounts of sample or high levels of contaminants are present.

In-Gel Digestion of Proteins for MALDI-MS Fingerprint Mapping

Polyacrylamide gel electrophoresis is a widely used technique for separating proteins from biological samples. Moreover, the development of two-dimensional gel electrophoresis (*UNIT 10.4*) has provided a tool for differential protein display, which allows for the quantitative analysis of thousands of proteins simultaneously. Complex biological questions can now be approached by analyzing differences in the two-dimensional gel patterns between control and experimental states (Fig. 16.4.1; Patterson and Aebersold, 1995; Arnott et al., 1998; Qiu et al., 1998).

Although highly sensitive staining methods could visualize proteins at increasingly low levels, originally protein identification was limited by the sensitivity of Edman sequencing. However, in the last few years mass spectrometry (MS) has emerged as a more sensitive, versatile, and rapid alternative, following the advent of electrospray ionization mass spectrometry (ESI-MS) and matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS). The advantages of MALDI-MS over ESI-MS include its relatively high tolerance to contamination from biological matrices, its high sensitivity, the relative ease of interpreting spectra from mixtures, and the formation of singly protonated molecular ions for tandem analysis (see *UNIT 16.6* for analysis of MALDI collision-induced dissociation, or MALDI-CID).

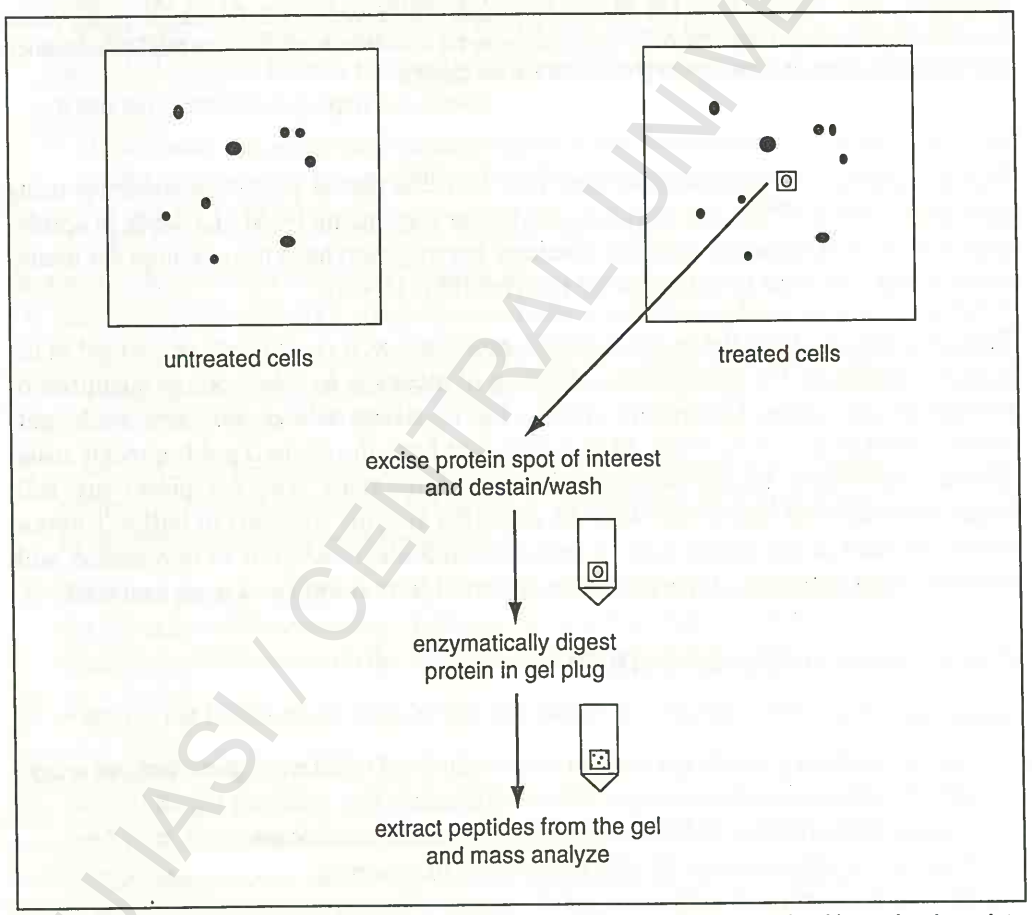

Figure 16.4.1 Protein in situ (in-gel) digestion. A spot from an SDS-PAGE gel is excised, cut into small particles (not shown), and placed in a silanized tube. The gel particles are destained, washed, dried, and rehydrated with a protease. The resulting peptides are extracted from the gel plug and subjected to mass measurement.

BOU IASI / CENTRAL UNIVERSITY LIBRARY

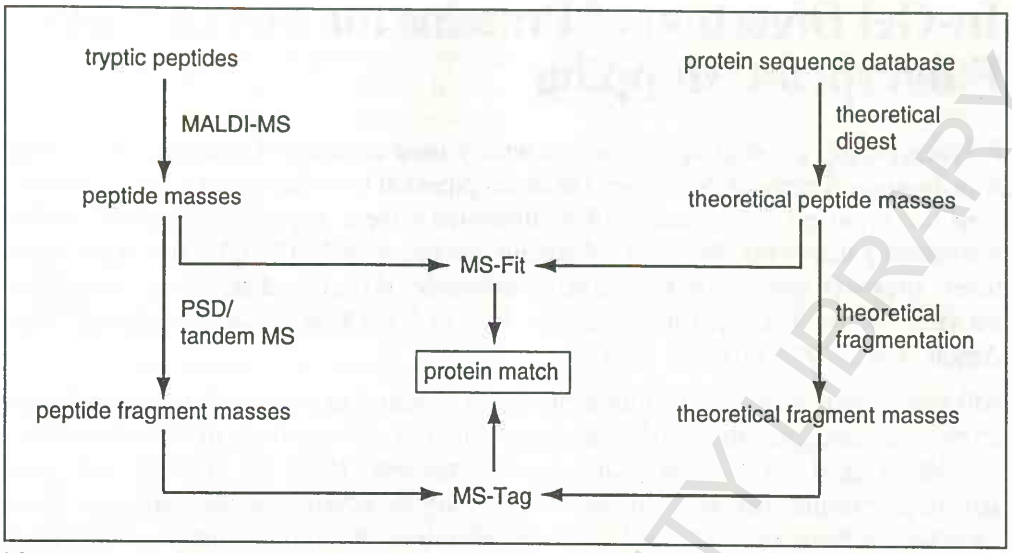

Figure 16.4.2 Peptide fingerprint mass mapping and peptide fragmentation mapping, using the database search programs MS-Fit and MS-Tag (*http://prospector.ucsf.edu*), respectively. The masses of peptides generated by enzymatic cleavage of the protein of interest (left) are matched with peptides generated by theoretical cleavage of each protein in the database (right) using the search program MS-Fit (see *UNIT 16.5* for further explanation). The masses of the post-source decay (PSD) ions or fragment ions (left) are matched with theoretical fragmentation products of each protein in the database (right) using the search program MS-Tag (see *UNIT 16.6* for details). For a conclusive protein identification, MS-Tag search results should confirm MS-Fit search results. When no reasonable matches are obtained, the protein may be unknown, in which case MS/MS sequence information is needed to design oligonucleotides for cloning.

Peptide fingerprint mass mapping (see *UNIT 16.5*) and partial peptide sequencing using post-source decay (PSD; see *UNIT 16.6*), and ladder sequencing by MALDI-MS in combination with algorithms for sequence database interrogation have the potential for identification and structural investigation of proteins (Fig. 16.4.2).

This protocol describes the in-gel digestion procedure as it is routinely performed in the authors' laboratory for peptide mass mapping of picomole to subpicomole quantities of protein derived from Coomassie- (*UNIT 10.5*) or silver-stained polyacrylamide gels (Shevchenko et al., 1996). First, SDS is removed from the excised gel fragments using several ammonium bicarbonate/acetonitrile washing steps. The gel pieces are subsequently dried and rehydrated with the digestion enzyme (trypsin) in buffer. Alternatively, the washed gel pieces may be reduced and S-alkylated prior to rehydration with enzyme. After digestion, the peptides are extracted from the gel and mass analyzed.

BASIC PROTOCOL

IN-GEL DIGESTION PROCEDURE

Materials

Stained polyacrylamide gel containing protein band of interest (*UNITS 10.1, 10.4 & 10.5*)
25 mM ammonium bicarbonate/50% (v/v) acetonitrile
10 mM dithiothreitol (DTT) in 25 mM ammonium bicarbonate
55 mM iodoacetamide in 25 mM ammonium bicarbonate
25 mM ammonium bicarbonate, pH 8
0.05 to 0.1 mg/ml trypsin (sequence grade; Promega) in 25 mM ammonium bicarbonate, pH 8
5% (v/v) trifluoroacetic acid (TFA)/50% (v/v) acetonitrile
0.65-ml tubes (e.g., PGC Scientific), silanized (*APPENDIX 3E*)

BRU IASTATE UNIVERSITY LIBRARY

Vacuum centrifuge
56°C water bath
Sonication bath

NOTE: To avoid or reduce contamination with human keratins, one should wear gloves and preferably work in a laminar-flow hood.

Excise and wash gel fragments

1. Excise protein bands/spots of interest from a stained polyacrylamide gel. Cut each gel piece into small particles (~1 mm^2) using a scalpel, and place into a 0.65-ml siliconized tube. Also cut out and dice a gel piece from a protein-free region of the gel, for a parallel control digestion to identify trypsin autoproteolysis products.

   The amount of protein loaded on the gel must be determined empirically, as it depends on properties of the specific protein (for example, degree of hydrophobicity and size). In general, picomole levels are preferred to lower levels, although some reports claim that femtomole sensitivities are attainable with in-gel digestion and mass spectrometry.

   The small gel particle size facilitates the removal of SDS (and Coomassie) during the washes, and improves enzyme access to the gel. For Coomassie-stained proteins, one gel particle per tube is probably sufficient protein. With faint silver-stained spots, particles can be pooled, but no more than three should be pooled as this will lead to excessive levels of contaminants. For a silver-staining protocol compatible with mass spectrometry, see Shevchenko et al. (1996).

2. Add ~100 µl of 25 mM ammonium bicarbonate/50% acetonitrile (or enough to immerse the gel particles) and vortex for 10 min. Use gel-loading pipet tips to remove the solution (pale blue in the case of Coomassie staining) and discard. Repeat this wash/dehydration step up to ~3 times.

   At this point, the gel slices shrink and become white. This visual criterion should be used to determine whether or not additional washes should be performed.

3. Dry gel particles for ~30 min in a vacuum centrifuge.

Perform reduction and alkylation (optional)

4. Add enough 10 mM DTT solution to cover the gel pieces, and reduce for 1 hr at 56°C.

   Steps 4 to 7 may be included when a maximum of protein coverage is required or when digesting a band from a one-dimensional gel. Proteins separated by two-dimensional gel electrophoresis are already reduced and alkylated, so their steps can be omitted.

5. Cool to room temperature and replace the DTT solution with roughly the same volume of 55 mM iodoacetamide solution. Incubate for 45 min at room temperature in the dark with occasional vortexing.

6. Wash gel pieces (rehydrate) with ~100 µl of 25 mM ammonium bicarbonate, pH 8, for 10 min while vortexing, and dehydrate with ~100 µl of 25 mM ammonium bicarbonate/50% acetonitrile. Repeat rehydration and dehydration.

7. Remove the liquid phase and dry the gel pieces in a vacuum centrifuge.

Digest protein sample

8. Rehydrate gel particles in 1 vol of 0.05 to 0.1 mg/ml trypsin solution by vortexing for 5 min. Do not add more solution than can be absorbed by the gel particles.

   The volume needed can be estimated by calculating the total gel volume excised (e.g., 2 mm × 8 mm × 1 mm = 16 mm^3 = 16 µl).

   The enzyme-to-substrate ratio employed for in-gel digestions (>1:10) is greater than for in-solution digestions due to hindered enzyme access to the protein substrate in the gel. Moreover, the relatively low salt concentration (25 mM) is used to reduce the possibility of subsequent salt interference with ionization in the mass spectrometer.

BCU IAS / CENTRAL UNIVERSITY LIBRARY

9. If necessary, overlay the rehydrated gel particles with a minimum amount of 25 mM ammonium bicarbonate to keep them immersed throughout digestion.

10. Incubate 12 to 16 hr at 37°C.

Recover peptides

11. Add 2 vol water, vortex for 5 min, and then sonicate for 5 min. Use a gel-loading tip to remove the peptide solution and transfer it to a silanized tube.

12. Perform two additional extractions using 2 vol of 5% TFA/50% acetonitrile.

    The silanized microcentrifuge tubes and the high TFA concentration are used to minimize adsorptive sample loss. Formic acid (5%) may be used as an alternative to TFA.

13. Concentrate recovered peptides by reducing the final volume of the extracts to ~10 µl in a vacuum centrifuge. Bring to 25 µl with 5% TFA/50% acetonitrile.

    Store the recovered peptides at –20°C until MALDI-MS is performed.

    For MALDI-MS analysis, mix 0.5 µl of the unseparated digest on the sample target with 0.5 µl of 20 mg/ml α-cyano-4-hydroxycinnamic acid in 0.1% TFA/50% acetonitrile and let air dry (for additional details, see UNIT 16.3, Basic Protocols 1 and 2). Insert sample target into the mass spectrometer and mass analyze as recommended by the manufacturer.

14. *Optional:* Decrease the amount of volatile salts by adding a few cycles of water (100 to 200 µl) and subsequently reducing the volume in a vacuum centrifuge.

    Salt reduction may improve mass signals, particularly at subpicomole levels.

COMMENTARY

Background Information

Generally, in-gel tryptic digests of proteins yield higher recovery of peptides than proteins digested after transblotting to polyvinylidene difluoride (PVDF) membranes (*UNIT 11.2*). Trypsin is the protease of choice for peptide mass fingerprinting because of its reliability and its substrate specificity, yielding peptides with C-terminal basic residues (Arg and Lys), which facilitates ionization and subsequent mass spectrometric sequencing. However, autolysis of the protease contributes contaminating peptides that can interfere with the analysis. For trypsin, this problem is partially overcome by using modified porcine enzyme. A few labile sites are often cleaved nonetheless, resulting in peptides with monoisotopic ions of 842.51, 2211.1045, and 2284.6, which may be used for internal accurate mass calibration of the spectrum. Endoprotease Lys-C is a good alternative to trypsin, because it produces less autolysis and it is more stable under denaturing conditions. Unfortunately, endo-Lys-C yields fewer, larger fragments that may be released from the gel particles less efficiently. However, larger average lengths provide greater specificity for the search algorithm (*UNIT 16.5*).

Critical Parameters and Troubleshooting

Low concentrations of ammonium bicarbonate in the digestion buffer give the best results for subsequent mass measurement by MALDI-MS. Adsorption of the released peptides to the sample tube and other surfaces is a problem when working in the femtomole range. To prevent sample losses, digestion is performed in silanized tubes. Moreover, the presence of organic solvent (10% acetonitrile) in the digestion buffer aids in solubility without degrading enzyme activity. The use of low amounts of pure, single-component detergents (e.g., *N*-octyl-β-D-glucoside) during digestion may also improve peptide recovery.

If a higher peptide coverage of the protein is required, the amount of organic solvent and the acidity of the matrix composition can be varied (see Cohen and Chait, 1996), as can the matrix. For example, α-cyano-4-hydroxycinnamic acid is the matrix of choice for best detection limits and post-source decay analysis. However, 2,5-dihydroxybenzoic acid (DHB), or DHB with fucose, yields spectra of peptide mixtures with the least suppression characteristics. If sequence coverage is still insufficient, use a microbore liquid chromatography/ESI-MS (LC-ESI-MS) system.

BJU IASTRAL UNIVERSITY LIBRARY

Anticipated Results

MALDI-MS analysis of unseparated tryptic digests generally yields 40% to 50% sequence coverage, although peptide recovery may be lower for hydrophobic proteins. Typically, with sufficient mass accuracy, four tryptic peptides may already be enough to identify a protein from the database using the search program MS-Tag (see *UNIT 16.6*).

Time Considerations

Generally, the in-gel digestion procedure is performed overnight. Shorter digestion times (e.g., 6 hr) are possible, but at the expense of less complete digestion.

Searching Sequence Databases Over the Internet: Protein Identification Using MS-Fit

BASIC PROTOCOL

Peptide fingerprint mass mapping is widely used for initial identification of proteins separated by gel electrophoresis (Cottrell, 1994; Jungblut and Thiede, 1997). This method involves the enzymatic in-gel digestion of proteins to generate peptides (*UNIT 16.4*), followed by mass measurement of the cleaved peptides. The experimental mass values are then compared with theoretical values from protein databases, calculated using the cleavage specificity of the enzyme. This protocol describes the use of the search program MS-Fit, which can be accessed through ProteinProspector at *http://prospector.ucsf.edu*. By using an appropriate scoring algorithm, the closest match or matches can be identified (Cottrell, 1994).

Peptide masses can be determined using either a matrix-assisted laser desorption/ionization time-of-flight (MALDI-TOF) or liquid chromatography/electrospray ionization (LC-ESI) mass spectrometer. MALDI-TOF mass spectrometry has been preferred for direct analysis of unseparated digest mixtures because of its tolerance to low levels of contaminants such as buffer salts. Because of the inherently high throughput, sensitivity, and simplicity of this technique, MALDI peptide mapping is now a powerful method for identification of proteins present at greater than or equal to ~0.5-pmol on a gel (Shevchenko et al., 1996).

Input data and set search parameters

1. Input the peptide masses obtained by mass spectrometry into a spreadsheet, and then copy and paste the values into the space for masses (*m/z*) in the MS-Fit program.

   Monoisotopic peptide masses from MALDI-TOF are preferred. Additional peptide mass values obtained in parallel from multiply charged ions (m/z) using electrospray ionization mass spectrometry along with charge state (z) are submitted at the same time. Average masses may also be used for the search; however, more false positive results will be obtained due to the lower mass accuracy.

2. Set mass tolerance, which should be no less than the mass accuracy obtained experimentally.

   Typical mass accuracy values for external calibration should be ~100 to 300 ppm for delayed-extraction MALDI-TOF, and ~100 ppm for electrospray orthogonal TOF. For internal calibration, ~5 to ~20 ppm should be used for both methods. Typical mass accuracy of ~ 0.5 Da is appropriate when regular MALDI-TOF (i.e., without delayed extraction) is used with internal calibration.

3. Choose a minimum number of peptides required for matching a particular protein in the database to generate a hit.

   The default value is four, which can be changed depending on the search output and the total number of peptides submitted. If the number of search results is too large (i.e., >25), the minimum number of peptides required to match can be increased gradually to eliminate the number of false positives. In general, if the search results give more than five different proteins, and the number of hits exceeds 25 (except all the hits referring to one protein in different species), a false positive is present.

4. Choose a protein database to use for the search. Choose any database listed in the program, such as NCBInr, Genpept, Swiss Prot, Owl, and dbEST.

   NCBInr is recommended as the first choice for the search, because it combines most of the public domain protein databases (though dbEST is not included) to generate the largest nonredundant protein database, and because it is updated most frequently. Swiss Prot may also be chosen because it is the best annotated database.

Contributed by C.R. Jiménez, L. Huang, Y. Qiu, and A.L. Burlingame

Current Protocols in Protein Science (1998) 16.5.1-16.5.6

Copyright © 1998 by John Wiley & Sons, Inc.

BCU LIBRARY CENTRAL UNIVERSITY

5. If the source of the protein of interest is known, select the species to perform a species-limited search. Alternatively, designate "all" for the species.

   In general, it is useful to designate "all," because it allows proteins occurring in different species with high homology to be found. Moreover, species prefiltering is imperfect because of poor usage of taxonomy (standard species naming conventions) in the databases. If the Latin taxonomic name for the species of interest is not known, see the NCBI Taxonomy Browser at http://www.ncbi.nlm.nih.gov/Taxonomy/tax.html.

6. Select the enzyme specificity and the number of "missed cleavage sites" to be employed.

   MS-Fit will search the peptide mass values submitted against calculated theoretical values of peptides cleaved by the specified enzyme. The termini of the matched peptides will be consistent with the cleavage specificity of the enzyme used to generate the peptide. Increasing the maximum number of allowed missed cleavages, enables matching to sequences with uncleaved sites internal to the peptide.

   If the digestion time employed is fairly long (>6 hr), it is possible (even likely) to find peptides present in the digest that are derived from nonspecific proteolytic cleavage. The option for employing the fictive enzyme "slymotrypsin" allows the occurrence of chymotryptic-like cleavages in tryptic digests. When using this choice it is important to increase the amount of missed cleavages allowed to three or more. It is also possible to combine the rules for two or more enzymes by adding options to the Enzyme item on the HTML form.

7. *Optional:* Select the molecular weight and pI range. Perform the first search with no molecular weight or pI restriction. Then adjust the range according to the search output.

   Because molecular weights from SDS-PAGE are not generally accurate, the range needs to be set at ±10 kDa. If the protein being analyzed is a processing or degradation product of a larger precursor, the molecular weight estimated from the gel would not be useful for the search.

8. Choose the desired types of modified residues to be searched.

   a. Specify modifications desired for cysteine residues to generate theoretical masses to match those cysteine-containing peptides that have been reduced and then alkylated with iodoacetic acid (carboxymethylation), iodoacetamide (carbamidomethylation), or 4-vinylpyridene (pyridylethylation).

   b. Specify additional chemical modifications of proteins that can be generated during PAGE, such as oxidation of methionine residues and acrylamide modification of cysteine residues.

   c. Specify peptide mass changes due to known posttranslational modifications, such as conversion of N-terminal glutamine to pyroglutamic acid, and phosphorylation of serine, threonine, and tyrosine.

   d. For any database entry with a methionine at the N terminus, specify whether the N-terminal peptide is to be considered in its original form or in a form where the methionine is removed and the penultimate amino acid is acetylated.

      If the database curators have removed the N-terminal methionine from the sequence, MS-Fit will not apply the acetylation modification.

Perform the search

9. Initiate the search. Two scoring systems are automatically displayed in search results: a modified MOWSE score (Pappin et al., 1993) and an MS-Fit rank. The higher the score, the higher number of peptide masses matched and the more likely the hit is of relevance. The output indicates the number of peptide masses matched and their corresponding sequences, and the matching protein's molecular weight, pI, accession number, species, and protein name. Click on the MS-digest index number to display

BCU IASI / CENTRAL UNIVERSITY LIBRARY

the coverage of the matched peptides in the entire protein sequence. Click on the accession number to link to the NCBI Entrez.

A detailed description of the MOWSE and MS-Fit scoring system can be found by clicking on this parameter in the program.

Currently, MS-Fit employs only a simple ranking system. The results are sorted so that if multiple database entries are matched, the more likely matches are listed higher in the rank. All database entries matching the input data and parameters are ranked on the following basis: (1) database entries with the least number of unmatched masses are ranked higher, and (2) among equivalent matches (those with the same rank), the results are sorted in order of increasing index number.

10. To perform an alternative search in homology mode, select the box that allows for a single amino acid substitution per peptide.

    In this mode, the MS-Fit option for other possible modifications is by-passed. In practice, the homology mode should only be used when one or more of the following conditions applies: the peptide mass data have excellent mass accuracy (±10 ppm or better), a narrow intact protein molecular weight filter is used, and/or the hits will be saved and searched using MS-Tag (UNIT 16.6). The minimum amount of peptides with no amino acid substitution (usually set at one or two) controls the protein entry pulled from the database. The output displays the necessary single amino acid substitution and the corresponding sequence consistent with the experimental peptide mass data (not the sequence present in the database). These predictions need to be confirmed by MALDI post-source decay (MALDI-PSD) or tandem mass spectrometry.

11. *Optional:* To use one ProteinProspector search program as a prefilter for another search program, save the hits (index numbers for matching database entries) from the first program to a user-specified file. Retrieve this file using the second program, so that only those matching database entries are searched by the second program.

    Saved hits from MS-Fit can be used by other programs such as MS-Tag (UNIT 16.6) and MS-Edman.

COMMENTARY

Background Information

Initially, protein identification using peptide mass mapping was hampered mainly by the poor mass accuracy obtained using MALDI mass spectrometers, making unambiguous identification difficult. Recently, the development of MALDI-TOF equipped with delayed extraction has dramatically improved the mass resolution and mass accuracy (Vestal et al., 1995; Edmondson and Russell, 1996) at the subpicomole to femtomole protein levels. Moreover, the rapid growth of gene and protein databases resulting from large-scale genome sequencing projects of different organisms now offers significant power for mass spectrometric identification and characterization of proteins isolated from gels.

The advantage of the improved mass accuracy using delayed extraction is increased search specificity of each peptide, leading to a better discrimination of true hits versus false-positive search results (Clauser et al., unpub. observ.). Finally, peptide mass mapping is not only useful for identification of proteins existing in databases, but also for cross-species identification. This possibility relies on sequence conservation between two proteolytic cleavage sites (a stretch of ~10 to 15 amino acids) in homologous proteins of different organisms (Cordwell et al., 1997; Shevchenko et al., 1997).

Critical Parameters and Troubleshooting

Measuring masses as accurately as possible is the single most important factor in achieving the highest certainty of protein identification in a peptide mass fingerprinting experiment (K.R. Clauser, unpub. observ.). The more accurate the masses measured, the lower the mass tolerance is set, and the more unambiguous the results obtained.

Several steps must be followed to obtain reliable protein identification using peptide mass mapping, especially when dealing with cases yielding ambiguous search results. First,

BIBLIOTECA CENTRAL UNEFM LIBRARY

sort out all of the unassigned experimental peptide masses by attributing them to posttranslationally modified peptides (such as modification of cysteine, methionine, and glutamine; see Basic Protocol, step 8), peptides with nonspecific cleavage sites, enzyme autolysis products, adducts (sodium, potassium, and matrix adducts), matrix peaks, and contaminants (keratins from human and other species). Series of peaks with constant mass differences can be attributed to organic polymers, which may come from tubes or may have been added during the isolation or preparation procedures (Jungblut and Thiede, 1997). If there are still quite a few abundant peaks left unassigned by such means, perform a second database search using the set of unmatched mass values excluded from the first match hit, because more than one protein may be present in the gel spot due to comigration during gel electrophoresis (Jensen et al., 1996). Second, try another digest using a different enzyme, search both sets of data, and select the results that are common to both lists. The chance of obtaining a protein with a high score in both searches is extremely small (Jensen et al., 1996).

When no match is found in the protein databases, this may suggest that the gene encoding the protein of interest has not yet been sequenced or cloned. However, it may be known as an expressed sequence tag (EST) that represents part of the protein. Therefore, it may be useful to screen a dbEST database. Search times will typically be longer because of the multiframe translations and because the dbEST file is >3 times larger than the NCBInr file. When an EST database is selected, the number for DNA frame translation needs to be set. A user should select frame mode 6 unless it is known that the database being searched contains sequences exclusively cloned in one direction or contains known genes with sequences already in frame. Of course, a longer search time will be required when using frame mode 6 instead of 3. Users can also generate their own database for searching; the instructions are in the ProteinProspector home page. Finally, to obtain a protein identification unambiguously, in the authors' opinion, it is always prudent and in fact may be necessary to obtain a partial peptide sequence to choose correctly among possible MS-Fit search result possibilities, unless information from other experiments indicates what the protein could possibly be.

Anticipated Results

As an example, the use of MS-Fit for unambiguous protein identification is illustrated here. Figure 16.5.1 shows a spectrum obtained by delayed-extraction MALDI-reflectron-TOF mass spectrometry of an in-gel-digested protein spot from a two-dimensional gel. The peptide masses were externally calibrated using peptide standards. Twelve monoisotopic (Burlingame and Carr, 1996) peptide masses (Fig. 16.5.1) were submitted into the MS-Fit program. In this case, four modifications were considered: conversion of peptide N-terminal

DU IAS CENTRAL UNIVERSITY LIBRARY

glutamine to pyroglutamate, oxidation of methionine, acetylation of protein N-terminus, and carboxymethylation or acrylamide modification of cysteine. The peptide mass tolerance was chosen as 100 ppm because external calibration was used. The default values were used for maximum number of missed cleavage sites and minimum number for peptides to match (both set at 4). A first search was performed without selection of a particular species (enter "all") or molecular weight range (1000 to ~100,000 Da). In this unrestricted search, 182 entries were obtained in the search results, of which the three highest ranking proteins all indicated proteasome subunit C8 in human and rat, due to the high interspecies homology.

To reduce the number of false positives, the molecular weight range was set at 20 to ~30 kDa, as determined by SDS-PAGE. Alternatively, the minimum number of peptides matched may be increased for this purpose. Thirteen entries were displayed in the second search result, and the high-ranking proteins were the same as in the first search. At this point, it is fairly certain that the protein of interest is proteasome subunit C8. This conclusion was further supported in the third search result, in which the species searched was limited to rat. As shown in Figure 16.5.2, 91% of the peaks submitted were matched. Two molecular ions matched modified peptides containing oxidized methionine (1130.5549, 1396.7758) and N-terminal acetylation (1960.0006). Subsequently, the latter peptide with $[M + H]^{1+}$ at 1960.006 was analyzed further using MALDI-PSD. This 42-Da shift in spectrum established the presence of N-terminal acetylation by observation of the appropriate ion sequence. When operating in reflectron mode, peptides containing oxidized methionine residues usually eliminate 64 u (mass units; $-SOCH_4$) as a neutral moiety, and the resulting metastable fragment ion is not focused well and thus typically shows a 62-Da loss from the parent ion. The peak at 1334.8252 represents a fragment ion from peptide of $[M + H]^{1+}$ at 1396.7758.

In conclusion, this protein can be successfully identified as rat proteasome subunit C8 using the MS-Fit program. However, in general, to ascertain reliable protein identification, it is always advisable to confirm such MS-Fit results with independent peptide sequence data using either MALDI-PSD or MALDI collision-induced dissociation (MALDI-CID).

Time Considerations

Search times depend on the database selected (also see Critical Parameters and Troubleshooting) and on the quality of data submitted (e.g., the amount of tryptic peptides, the mass accuracy). They can vary from less than 1 min to 15 min or more.

Searching Sequence Databases Over the Internet: Protein Identification Using MS-Tag

Although peptide mass mapping is fast and simple, its success can be compromised by the purity of the protein in one gel spot, errors in the sequence database, and the detection of too few peptides in the MS map of a given protein to permit reliable database matching. In those cases, partial amino acid sequence that is determined using post-source decay (PSD) analysis or tandem mass spectrometry is required to establish the correct protein identification among possibilities suggested by MS-Fit (*UNIT 16.5*).

Post-source decay (Kaufmann et al., 1993, 1994) involves the detection of the fragmentation product ions (metastable ions) of a selected mass value window containing the precursor ion chosen, that occur in the field-free region between the ion source and the reflectron. For a discussion of the basic principle of MALDI-PSD-MS for peptide sequencing, refer to *UNIT 16.1*. This unit covers some of the practical issues in obtaining and analyzing a typical PSD spectrum. The Basic Protocol introduces MS-Tag (see *http://prospector.ucsf.edu*), a database interrogation program that enables the identification of proteins with a limited number of peptide fragment ions by matching existing database sequences. Although a typical PSD spectrum will usually not provide enough sequence ions for de novo manual sequence interpretation (particularly in the higher mass range, e.g., >500 to 800 Da), these ions together with the parent ion are statistically much better identifiers in database searching than only the molecular weights of tryptic peptides. Unlike peptide fingerprinting, database searching based on fragment ion information is often able to identify a single peptide sequence in the database that matches all the input information.

Several computer programs employing fragment ion information to search databases are available on the internet (see *http://donatello.ucsf.edu/onramp.html* and sites listed therein). Among them, MS-Tag is a user-friendly program that simultaneously considers a variety of ion types, but still allows single-mismatch-tolerant searching. However, the authors suggest that a frequent user of MS-Tag should be able to interpret sequences from those spectra that do contain sufficient information to enable de novo interpretation.

Although MALDI-PSD database searching is a widely used tool, an alternative method is analysis by MALDI collision-induced dissociation (MALDI-CID). This is presented in the Alternate Protocol.

DATABASE SEARCHING WITH MS-TAG

BASIC PROTOCOL

The basic principles of MS-Tag are detailed in the instruction section of the Web site (*http://prospector.ucsf.edu*). Users can find explanations for every input parameter by just clicking on the highlighted terms.

1. Type in the mass and charge state of the parent ion (masses detected in MS mode are preferred).
2. Define the parent ion mass tolerance.

   The tolerance range will depend on the instrument.
3. Input all fragment ions and define their mass tolerance, which is usually higher than the parent ion mass tolerance.

   Ions with higher intensities are preferred if a number of ions are available.

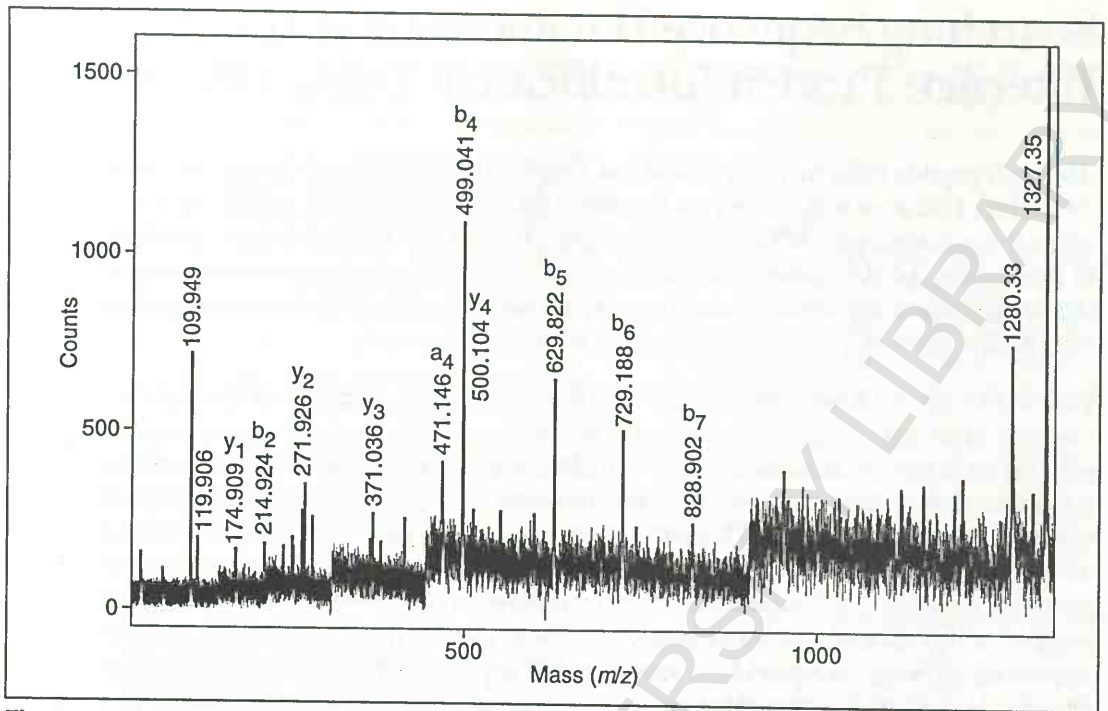

Figure 16.6.1 PSD spectrum of a tryptic peptide of an unknown protein isolated from mouse liver. This peptide has sequence homology to bovine inorganic pyrophosphatase (DVFMVVEVPR), where one mutation is found (from E1 to D1).

4. Specify the type of input masses (e.g., all monoisotopic, all average, or parent ion is monoisotopic and fragment ions are average).

5. Specify the database searched and the type of frame translation if a nucleotide database is selected.

   The ability to search against MS-Fit hits is particularly useful when the target protein is not in current protein databases but is included in the expressed sequence tag (EST) database. The EST databases are currently much larger than other databases. Therefore, direct MS-Tag searching against an EST database is statistically much more demanding and may fail due to the much longer search time.

6. Specify the species from which the protein of interest is isolated, the protein molecular weight range, the type of enzyme used for protein digestion, the type of cysteine modification, and the maximum unmatched fragment ions. Default parameters may be used for other choices listed on the Web page.

7. Specify the search mode as identity or homology. Search in identity mode first; if not successful, then search in homology mode. Begin search.

   Typical results are depicted in Figure 16.6.1 and Figure 16.6.2, and are discussed in Anticipated Results.

SEQUENCE ANALYSIS USING MALDI-CID

Although MALDI-PSD combined with database searching (see Basic Protocol) has emerged as the primary approach for identifying gel-separated proteins, limitations exist. For example, due to the nature of the gating device, the resolution of a precursor ion selection cannot exceed ~100 (M/ΔM) without serious loss of sensitivity. This value would barely enable the distinction between a parent ion at *m/z* 2000 and its water-loss ion. More importantly, the performance of PSD tends to be unpredictably dependent on the amino acid composition of individual peptides. This may be avoided by relying on high-energy MALDI collision-induced dissociation (MALDI-CID), because the use of collision gas with current reflectron instruments usually increases the intensities of product ions in the low mass region only (mainly immonium ions; Stimson et al., 1997). Often complete sequence ion information is needed to determine the sequence of peptides de novo (particularly important if the protein of interest is not represented in any current databases) or in studies of the structure of posttranslational and xenobiotic modifications. In many cases, these problems may be addressed by high-energy MALDI-CID.

High-energy MALDI-CID is often performed on hybrid instruments, such as a tandem double-focusing magnetic orthogonal-acceleration time-of-flight (TOF) mass spectrometer (Bateman et al., 1995; Medzihradszky et al., 1996, 1997). The use of a double–focusing sector mass analyzer (such as MS1, a mass analyzer for separating parent ions using appropriate electric fields, and in combination with magnetic fields) enables the selection of a monoisotopic precursor ion with mass up to *m/z* 2000. The ions selected by MS1 then collide with xenon gas to generate a variety of ion types, which are then accelerated into a linear TOF analyzer orthogonal to the original direction of travel. The sampling frequency for this mode of operation is 100%. The signal-to-noise ratio in a MALDI-CID spectrum is far superior to that of a PSD spectrum. More importantly, many ion types that are unique to the high-energy process (e.g., d, v, and w ions) can be observed in a high-energy MALDI-CID spectrum but not in a PSD spectrum (which is very similar to a low-energy CID process). These high-energy ions have considerable value in the de novo determination of complete and unambiguous amino acid sequence (Medzihradszky and Burlingame, 1994), such as discrimination of leucine and isoleucine residues (Biemann, 1990). Therefore, MALDI-CID holds the promise to characterize unknown proteins, particularly those not represented in any current database, and can more explicitly determine the sites of posttranslational or xenobiotic modifications on target proteins.

For example, Figure 16.6.3 shows a MALDI-CID spectrum of a tryptic peptide of human serum albumin (HPYFYAPELLFFAK*R, *m/z* 2360.5) that is modified by benoxaprofen glucuronide (Qiu et al., 1998), as indicated by the asterisk in the sequence above. As benoxaprofen contains a chlorine atom, the $^{12}C^{35}Cl$ isobar for the precursor mass was selected by MS1 for CID analysis. In this spectrum, all C-terminal sequence ions (y ions) together with their corresponding high-energy ions (v and w ions) allow the unambiguous determination of both the sequence and the site of modification of this peptide. The 461-unit mass shift of all y ions except y_1 indicates the benoxaprofen glucuronide modification on the lysine residue near the C terminus. The presence of w_6 (*m/z* 1183.5) and w_7 (*m/z* 1296.6) distinguishes leucines from isoleucines (for isoleucines, w_6 and w_7 should be at *m/z* 1197.5 and 1310.6, respectively). The N-terminal sequence ions (b ions), internal fragments, and fragments from the drug moiety also aid or confirm the final data interpretation.

COMMENTARY

Background Information

In MALDI-TOF-MS spectra obtained in a reflectron mode, most of the fragment ions (metastable) formed in the field-free region cannot be observed because they are not in energy focus. However, fragment ions with masses close to the mass value of the parent ion can still be observed, albeit with both lower resolution and mass accuracy. To focus these metastable fragment ions throughout the entire mass range, the reflectron voltage needs to be successively stepped down to record approximately nine to fourteen consecutive mass scale segments, depending on the mass of the parent ion. These partially overlapping mass segments are then mass resolved to an accuracy of ±0.3 Da, and can be calibrated and stitched together to form a full PSD mass spectrum. One may still find that fragment ion peaks with different masses recorded in one segment have different mass accuracy (sometimes the difference can be as high as 0.3 Da within a segment). Typically, ions with higher masses will have better mass accuracy than those with lower masses because they are better focused by the reflectron. More recently introduced curved-field reflectrons (Cordero et al., 1995) focus all the ions into a small region near the exit of the reflectron. This new feature enables approximately ten times faster acquisition of the product ion spectrum, because it can simultaneously collect the entire PSD mass spectrum without changing the reflectron voltage.

Critical Parameters and Troubleshooting

After submitting a search request, oftentimes no match is retrieved for a given set of input parameters, and the MS-Tag program suggests decreasing the specificity of the input parameters. Because there are many restrictions that can be changed, it may be difficult for a new user to pinpoint the critical parameters that prevent the search from retrieving hits. In this situation, the following troubleshooting suggestions may save time.

BOSTON UNIVERSITY LIBRARY

1. Verify that the mass calibration of the data is correct. Mass accuracy of the parent ion is very important for minimizing false positives.

2. Do not specify the species in the first search, because some species may have different names in different databases. Specify species only when too many hits have been identified.

3. Do not limit molecular weight range.

4. Provide a broad enough mass tolerance window for fragment ions. Fragment ions are differentially focused by the reflectron, so their mass accuracy varies significantly.

5. Deselect enzyme specificity. Nonspecific enzymatic cleavages often occur, particularly after overnight incubations.

6. Increase the number of ions allowed to be unmatched when no hit is found.

7. Deselect immonium ions.

8. Use the NCBInr database as a first choice. If nothing is found, search other databases.

If none of these changes results in search hits, switch to homology searching. In homology search mode, it is very important to maintain the maximum specificity of input data, or too many false positives may be generated. Additionally, only peptides with one amino acid difference from a peptide sequence existing in the database can be retrieved. If two mutations occur in your peptide, no hit will be found. For peptides containing oxidized methionine, homology mode must be used. In this case, the parent mass shift can be limited to ±17 Da.

Anticipated Results

PSD spectra are usually acquired at a laser power well above the threshhold required for observation of ions corresponding to the intact analytes (Riahi et al., 1994). Whether this enhancement of internal (vibronic) energy is due to the desorption of parent ions with deposition of higher internal energy or to the increased collision number resulting from a larger matrix plume volume is currently not known. The particular results obtained during a PSD experiment are also dependent on the properties of the particular matrices used (see MALDI sample preparation, *UNIT 16.3*; Stimson et al., 1997). For PSD analysis of peptides, α-cyano-4-hydroxy-*trans*-cinnamic acid (HCCA) is the matrix of choice because it seems to promote ion fragmentation more than other matrices.

The following example illustrates the use of PSD combined with MS-Tag searching of the database for protein identification. Figure 16.6.1 shows the PSD spectrum of a tryptic peptide of an unknown protein isolated from mouse liver. An MS-Tag search of the NCBInr database in homology mode yields one single peptide sequence (DVFHMVVEVPR) with a single amino acid mismatch, compared to the sequence of a tryptic peptide from bovine inorganic pyrophosphatase (Fig. 16.6.2).

Time Considerations

Search times depend on the database selected and on the quality of data submitted (e.g., the amount of tryptic peptides, the mass accuracy). They can vary from less than 1 min to 15 min or more.

CHAPTER 19
Identification of Protein Interactions

INTRODUCTION

Protein interactions are intrinsic and vital to many cellular processes. In recent years many new techniques have been developed for the study of this important topic; the review by Phizicky and Fields (1995) provides an excellent general overview of this subject. This chapter describes biochemical, physical, and genetic methods that are used to detect specific protein interactions. A companion chapter in preparation will present a series of complementary methods that are used to provide quantitative information about protein interactions, such as the strength and kinetics of binding.

This chapter begins with brief overview of the analysis of protein interactions in which some of the basic kinetic and thermodynamic concepts are described (*UNIT 19.1*). This is followed by a presentation of one of the most widely used approaches for detecting protein interactions, the yeast two-hybrid/interaction trap system (*UNIT 19.2*). In this genetic method transcriptional activity is used as a measure of protein interaction.

Future plans for this chapter include units on a phage-based expression cloning system used to identify interacting proteins, and surface plasmon resonance (SPR), another useful method for discovery and detection of protein interactions that is gaining in popularity.

Analysis of Protein-Protein Interactions

BASIC CONCEPTS

Most of the work of living organisms is performed by proteins. Proteins do their work by acting on other macromolecules: nucleic acids, carbohydrates, lipids, and, especially, other proteins. Inside cells, protein-protein interactions are instrumental in enzymatic actions upon protein substrates and in the fleeting and lasting protein assemblies that govern signal transduction, cell division, DNA replication, and transcription initiation. Outside cells, protein interactions allow cells to talk with each other: ligands expressed on the cell surface often bind protein receptors expressed on adjacent cells, and secreted protein ligands bind receptors on distant cells. Techniques to detect and study protein-protein interactions have become steadily more easy to use in recent years. This unit, and those that follow, lay them out.

Qualitative statements about protein-protein interactions inform much of the current biological literature. This unit presents the basics for understanding such qualitative statements—i.e., the quantitative concepts by which these can be evaluated. Colloquially, protein interactions are often referred to as either **stable** or **transient**. The statement that a certain interaction is **stable** is typically used when the interacting proteins form a complex. Membership in a protein complex is most commonly defined operationally—based on detection of the protein after its coprecipitation with a reagent specific for another member of the complex—but is sometimes defined based on a strong and biologically plausible interaction in a two-hybrid experiment. Proteins that form such complexes with one another are often referred to as **partners**. By contrast, the term **transient** is used to denote, e.g., interactions between an enzyme and a protein substrate.

As the preceding example suggests, there is no particular correlation between the stability of a protein interaction and its biological significance. It is also worth noting that there are exceptions to commonly held assumptions about stable and transient interactions: some interactions observed in coprecipitation experiments have no biological validity, whereas some enzyme-substrate interactions last for minutes. For these reasons, it is often useful to think of protein interactions in more formal terms. The strength, or **affinity**, of an interaction between two proteins is described by **equilibrium parameters**. The speed at which an interaction occurs, and at which interacting proteins come apart, is given by **kinetic parameters**.

EQUILIBRIUM PARAMETERS

The strength of an interaction can be given as the **equilibrium dissociation constant**, K_d, or by its reciprocal, K_a (discussed below). When two proteins A and B associate, the K_d is given by

$$K_d = \frac{[A][B]}{[AB]}$$

where [AB] is the concentration of the complexed species and [A] and [B] are the concentrations of the noncomplexed species. Concentrations are given in molar terms, as is the K_d.

There are two useful special cases to keep in mind. First, when A and B are present in equal concentration, the concentration at which half of each protein is present in the form of AB complex is the K_d. Second, when the concentration of A vastly exceeds the

BU IASI / CENTRAL UNIVERSITY LIBRARY

Table 19.1.1 Dissociation Constants for Some Biologically Significant Interactions

Interaction	K_d
Streptavidin-biotin binding	10^{-14} M
Antibody-antigen interaction with good antibody	10^{-8} to 10^{-10} M
DNA binding protein with specific site	10^{-8} to 10^{-10} M
Antibody-antigen interaction with weak antibody	10^{-6} M
Enzyme-substrate interations	10^{-4} to 10^{-10} M
Cooperative interaction between DNA-bound phage repressors	10^{-4} M
Cooperative interaction between phage repressor and *E. coli* RNA polymerase	10^{-2} M

concentration of B (say, by 100-fold)—typically indicated [A] >> [B]—the concentration of A at which half of the B is found in the AB complex approximates K_d.

Typical K_d values for biologically significant interactions are given in Table 19.1.1. Note that many significant interactions are weak.

Alternatively, affinity may be given as an **equilibrium association constant**, K_a. The K_a is simply

$$K_a = \frac{[AB]}{[A][B]}$$

In other words, it is the reciprocal of the equilibrium dissociation constant: $K_a = 1/K_d$. Association constants are used less often than K_d, but do appear in the literature of some subfields—for example, in descriptions of antibody-antigen interactions.

The strength of an interaction is directly proportional to the change in Gibbs free energy (ΔG) when A and B interact, which is given by

$$\Delta G = \Delta H - T\Delta S$$

where T is the temperature in degrees Kelvin, ΔS is the change in entropy (S), and ΔH is the change in enthalpy (H). ΔG is given in units of kilocalories/mole (kcal mol^{-1}). An increase in the free energy of an interaction by 1 kcal decreases the K_d by a factor of ~7. Note that the temperature affects the entropy term of the equation. As the temperature decreases, reactions driven by enthalpy are less affected by losses in entropy, and are usually favored. By contrast, reactions whose free energy is derived largely from favorable changes in entropy are disfavored at lower temperatures. This means that the dependence of a protein association on temperature can often provide a clue to which term predominately contributes to the free energy change involved in that association.

The relationship between K_a and ΔG is defined as follows:

$$\Delta G^0 = -RT \ln \frac{[AB]}{[A][B]}$$

$$\Delta G^0 = -RT \ln K_a = -RT \ln\left(\frac{1}{K_d}\right) = -RT \ln K_d$$

BGU IASJ CENTRAL UNIVERSITY LIBRARY

where ΔG^0 is the free energy change under standard conditions (25°C); R is the universal gas constant (1.9872 calmole^{-1}K^{-1}); and T is the temperature in degrees Kelvin (25°C is 289.1 K). Therefore,

$$\Delta G^0 = 0.588 \ln K_d$$

and, since $\ln x = 2.303 \log_{10} x$, $\Delta G^0 = 1.36 \log_{10} K_d$. For example:

$$\text{(a) } K_d = 1 \times 10^{-14}, \text{ then } \Delta G^0 = -19.04 \text{ kcal mol}^{-1}$$

$$\text{(b) } K_d = 1 \times 10^{-2}, \text{ then } \Delta G^0 = -2.72 \text{ kcal mol}^{-1}$$

The strepavidin-biotin reaction (a) is intrinsically more favorable in the direction of binding, [AB] formation, than the low-affinity interaction (b) involving phage repressor (see Table 19.1.1). It should be pointed out that the DG values calculated above assume that the molar ratio of reactants [A] [B] and product [AB] is 1 M (standard state).

Many (but by no means all) biologically important protein interactions seem to be largely driven by ΔH, or changes in enthalpy. That is fortunate, in that changes in entropy on binding are very hard to quantitate, or even think about precisely. For example, proteins in solution are surrounded by water molecules that form hydrogen bonds with surface residues. When two proteins interact, the ordered arrangement of the water molecules that surrounded the interacting surfaces of the proteins is often disrupted, and this loss of order provides an entropically favorable term to the free energy of the interaction. Such changes in the free energy due to entropy are very hard to predict. By contrast, enthalpic changes are easier to understand. If formation of one hydrogen bond liberates about –1 kcal M^{-1}, and formation of a particular ionic contact liberates about –2 kcal M^{-1}, then the energies of these changes are additive such that the formation of both bonds usually liberates –3 kcal M^{-1}—which means that the K_d is decreased >100-fold by the enthalpic changes.

Kinetic Parameters

The above descriptions of protein interactions make no reference to the speed at which association or dissociation occurs. These speeds are given by **kinetic parameters**.

The **dissociation rate constant**, k_{dissoc}, gives the speed at which the AB complex dissociates into A and B (AB → A + B). k_{dissoc} is a first-order rate constant—i.e., one that is dependent on the concentration of one species, in this case the AB complex—and is given by the rate of decrease in the concentration of AB:

$$k_{dissoc}[A][B] = \frac{-d[AB]}{dt}$$

Its units are those of reciprocal time (t in the equation), usually given in sec^{-1}. For example, a dissociation rate constant of 10^{-4} sec^{-1} means that one in 10^4 of the AB complexes present comes apart each second.

Similarly, the **association rate constant**, k_{assoc}, gives the speed at which A and B associate to form an AB complex (A + B → AB). This is a second-order reaction—i.e., its speed depends on the concentrations of both A and B—and its rate constant is is given by

$$k_{assoc}[A][B] = \frac{+d[AB]}{dt}$$

Its units are those of reciprocal concentration × reciprocal time, typically given in M^{-1} sec^{-1}.

BCU IISC CENTRAL UNIVERSITY LIBRARY

For example, suppose that protein A is present at a concentration of 10^{-6} M in a cell, that protein B is injected to a nuclear concentration of 10^{-5} M, and that the rate constant for this antibody-antigen association is 10^{-4} M^{-1} sec^{-1}. After injection, the concentration of AB will be

$$[AB] = [A] \times [B] \times K_{assoc}$$

$$= (10^{-6}\,M)(10^{-5}\,M)(10^{-4}\,M)$$

$$= 10^{-7}\ M\ sec^{-1}$$

That is, in the first second after mixing, 10^{-7} M of AB complex will form. Every 10-fold increase in the concentration of either reactant increases the rate of product formation 10-fold.

Note that, at equilibrium, by definition,

$$\frac{d[AB]}{dt} = 0$$

and, therefore, for the AB interaction,

$$K_d = \frac{k_{dissoc}}{k_{assoc}}$$

The fact that the strength of equilibrium interactions reflects the speed of associations and dissociations has important consequences. To understand this, imagine two pairs of proteins that interact with the same K_d. Proteins A and B come together slowly, but, once the AB complex forms, it takes a long time to come apart. By contrast, proteins C and D come together rapidly, and the CD complex dissociates rapidly. There are two common cases in which these kinetic differences in the AB and CD associations would be significant.

One is in measurement. Many techniques, such as the "pulldown" and immunological coprecipitation techniques described in this chapter, rely on the the fact that proteins remain associated during some sequence of steps, while they are being separated from other proteins in a mixture and while the isolated complex is being rinsed. No matter how tightly the proteins associate, if they come apart before their complex can be separated and rinsed, the complex will not be detected. Moreover, if the AB and CD interactions have the same K_d, but CD comes apart more rapidly, then a coprecipitation experiment can falsely suggest that the CD association is weaker.

The second case concerns the biological effects. Many biological phenomena, such as the transcription phenotypes resulting from protein-protein interactions in two-hybrid experiments (*UNIT 19.3*), seem to be well-described by consideration of equilibrium measurements. However, it is worth keeping in mind that any biological process that results from the association of two proteins requires a minimum time to occur. For some enzyme-substrate interactions, the minimum time may be on the order of microseconds, but for others, such as the initiation of DNA replication, it may be measured in seconds. If the complex dissociates faster than the minimum time, then, no matter how tight the interaction, the process will not occur. If AB and CD have the same K_d, but CD dissociates faster, the association may not produce a biological effect.

Interaction Trap/Two-Hybrid System to Identify Interacting Proteins

To understand the function of a particular protein, it is often useful to identify other proteins with which it associates. This can be done by a selection or screen in which novel proteins that specifically interact with a target protein of interest are isolated from a library. One particularly useful approach to detect novel interacting proteins—the two-hybrid system or interaction trap (see Figs. 19.2.1 and 19.2.2)—uses yeast as a "test tube" and transcriptional activation of a reporter system to identify associating proteins (see Background Information). This approach can also be used specifically to test complex formation between two proteins for which there is a prior reason to expect an interaction.

In the basic version of this method (see Fig. 19.2.2), the plasmid pEG202 or a related vector (see Fig. 19.2.3 and Table 19.2.1) is used to express the probe or "bait" protein as a fusion to the heterologous DNA-binding protein LexA. Many proteins, including transcription factors, kinases, and phosphatases, have been successfully used as bait proteins. The major requirements for the bait protein are that it should not be actively excluded from the yeast nucleus, and it should not possess an intrinsic ability to strongly activate transcription. The plasmid expressing the LexA-fused bait protein (see Table 19.2.1) is used to transform yeast possessing a dual reporter system responsive to transcriptional activation through the *LexA* operator. In one such example, the yeast strain EGY48 (see Table 19.2.2) contains the reporter plasmid pSH18-34. In this case, binding sites for LexA are located upstream of two reporter genes. In the EGY48 strain, the upstream activating sequences of the chromosomal *LEU2* gene—required in the biosynthetic pathway for leucine (Leu)—are replaced with *LexA* operators (DNA binding sites). pSH18-34 contains a *LexA* operator–*lacZ* fusion gene. These two reporters allow selection for transcriptional activation by permitting selection for viability when cells are plated on medium lacking Leu, and discrimination based on color when the yeast is grown on medium containing Xgal (*APPENDIX 4A*).

In Basic Protocol 1, EGY48/pSH18-34 transformed with a bait is characterized for its ability to express protein (Support Protocol 1), growth on medium lacking Leu, and for the level of transcriptional activation of *lacZ* (see Fig. 19.2.2A). A number of alternative strains, plasmids, and strategies are presented which can be employed if a bait proves to have an unacceptably high level of background transcriptional activation.

In an interactor hunt (Basic Protocol 2), the strain EGY48/pSH18-34 containing the bait expression plasmid is transformed (along with carrier DNA made as described in Support Protocol 2) with a conditionally expressed library made in the vector pJG4-5 (see Fig. 19.2.6 and Table 19.2.3). This library uses the inducible yeast *GAL1* promoter to express proteins as fusions to an acidic domain ("acid blob") that functions as a portable transcriptional activation motif (act) and to other useful moieties. Expression of library-encoded proteins is induced by plating transformants on medium containing galactose (Gal), so yeast cells containing library proteins that do not interact specifically with the bait protein will fail to grow in the absence of Leu (see Fig. 19.2.2B). Yeast cells containing library proteins that interact with the bait protein will form colonies within 2 to 5 days, and the colonies will turn blue when the cells are streaked on medium containing Xgal (see Fig. 19.2.2C). The DNA from interaction trap positive colonies can be analyzed by polymerase chain reaction (PCR) to streamline screening and detect redundant clones in cases where many positives are obtained in screening (see Alternate Protocol 1). The plasmids are isolated and characterized by a series of tests to confirm specificity of the interaction with the initial bait protein (Support Protocols 3 to 5). Those found to be specific are ready for further analysis (e.g., sequencing).

BUFFALO CENTRAL LIBRARY

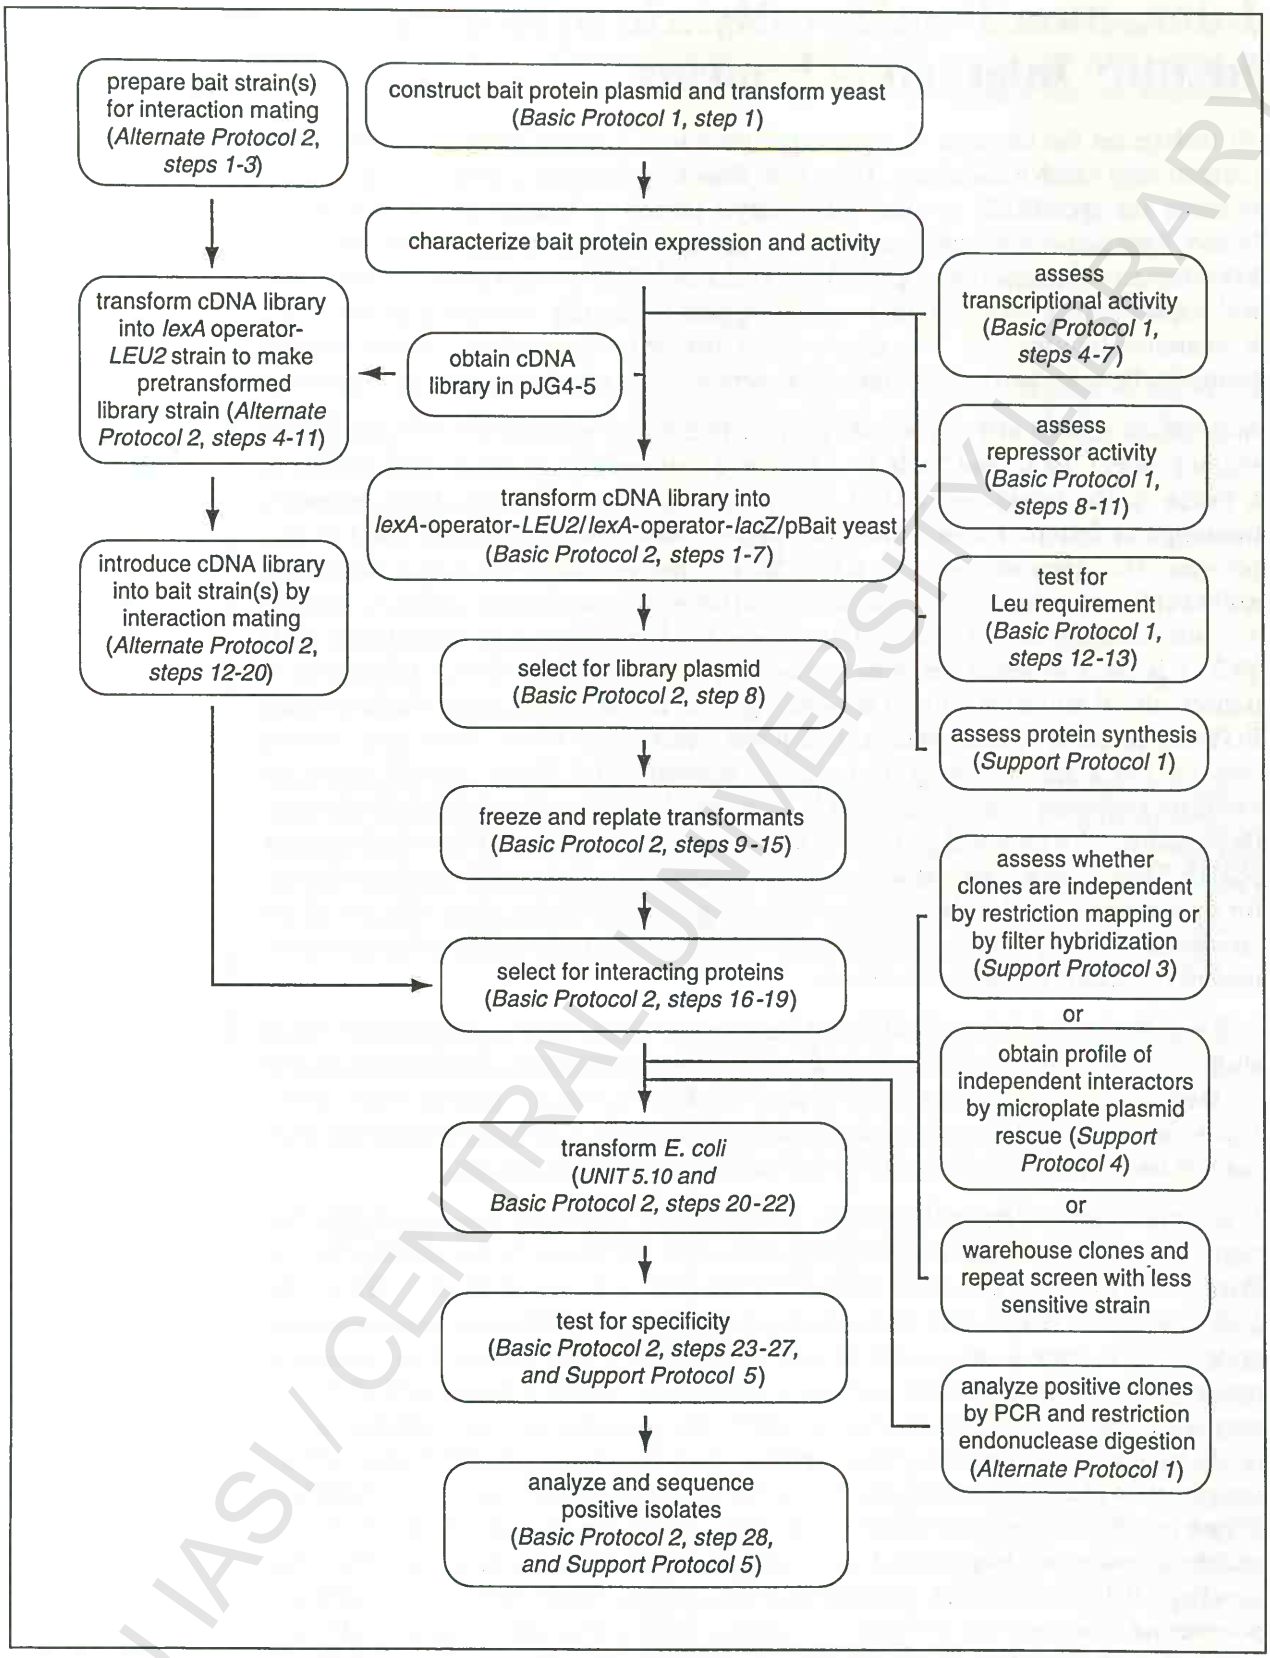

Figure 19.2.1 Flow chart for performing an interaction trap.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

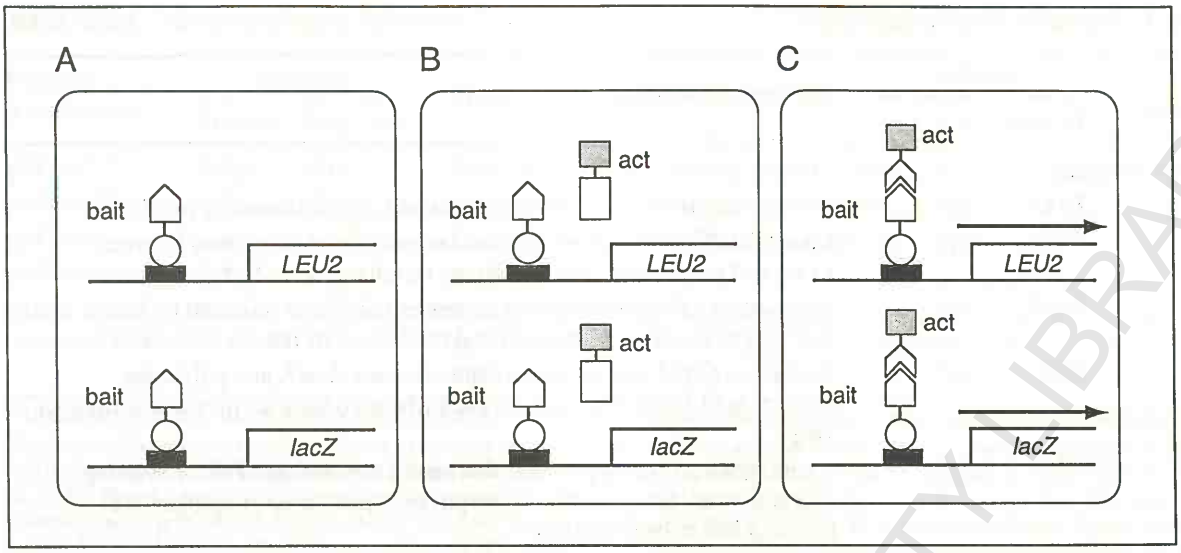

Figure 19.2.2 The interaction trap. (**A**) An EGY48 yeast cell containing two *LexA* operator–responsive reporters, one a chromosomally integrated copy of the *LEU2* gene (required for growth on –Leu medium), the second a plasmid bearing a *GAL1* promoter–*lacZ* fusion gene (causing yeast to turn blue on medium containing Xgal). The cell also contains a constitutively expressed chimeric protein, consisting of the DNA-binding domain of LexA fused to the probe or bait protein, shown as being unable to activate either of the two reporters. (**B**) and (**C**), EGY48/pSH18-34/pbait-containing yeast have been additionally transformed with an activation domain (act)–fused cDNA library in pJG4-5, and the library has been induced. In (B), the encoded protein does not interact specifically with the bait protein and the two reporters are not activated. In (C), a positive interaction is shown in which the library-encoded protein interacts with bait protein, resulting in activation of the two reporters (arrow), thus causing growth on medium lacking Leu and blue color on medium containing Xgal. Symbols: black rectangle, *LexA* operator sequence; open circle, LexA protein; open pentagon, bait protein; open rectangle, library protein; shaded box, activator protein (acid blob in Fig. 19.2.6).

When more than one bait will be used to screen a single library, significant time and resources can be saved by performing the interactor hunt by interaction mating (see Alternate Protocol 2). In this protocol, EGY48 is transformed with library DNA and the transformants are collected and frozen in aliquots. For each interactor hunt, an aliquot of the pretransformed EGY48/library strain is thawed and mixed with an aliquot of a bait strain transformed with the bait expression plasmid and pSH18-34. Overnight incubation of the mixture on a YPD plate results in fusion of the two strains to form diploids. The diploids are then exposed to galactose to induce expression of the library-encoded proteins, and interactors are selected in the same manner as in Basic Protocol 2. The advantage to this approach is that it requires only one high-efficiency library transformation for multiple hunts with different baits. It is also useful for bait proteins that are somewhat toxic to yeast; yeast expressing toxic baits can be difficult to transform with the library DNA.

CHARACTERIZING A BAIT PROTEIN

BASIC PROTOCOL 1

The first step in an interactor hunt is to construct a plasmid that expresses LexA fused to the protein of interest. This construct is transformed into reporter yeast strains containing *LEU2* and *lacZ* reporter genes, and a series of control experiments is performed to establish whether the construct is suitable as is or must be modified, and whether alternative yeast reporter conditions should be used. These controls establish that the bait protein is made as a stable protein in yeast, that it is capable of entering the nucleus and binding *LexA* operator sites, and that it does not appreciably activate transcription of the *LexA* operator–based reporter genes. This last is the most important constraint on use of this system. The LexA-fused bait protein must not activate transcription of either re-

BUHSL / CENTRAL UNIVERSITY LIBRARY

Table 19.2.1 Interaction Trap Components[a,b]

Plasmid name/source	Selection		Comment/description
	In yeast	In *E. coli*	
LexA fusion plasmids			
pEG202[c,d,e]	*HIS3*	Ap^r	Contains an *ADH* promoter that expresses LexA followed by polylinker
pJK202	*HIS3*	Ap^r	Like pEG202, but incorporates nuclear localization sequences between LexA and polylinker; used to enhance translocation of bait to nucleus
pNLexA[e]	*HIS3*	Ap^r	Contains an *ADH* promoter that expresses polylinker followed by LexA; for use with baits where amino-terminal residues must remain unblocked
pGilda[d]	*HIS3*	Ap^r	Contains a *GAL1* promoter that expresses same LexA and polylinker cassette as pEG202; for use with baits whose continuous presence is toxic to yeast
pEE202I	*HIS3*	Ap^r	An integrating form of pEG202 that can be targeted into *HIS3* following digestion with *Kpn*I; for use where physiological screen requires lower levels of bait to be expressed
pRFHM1[e,f] (control)	*HIS3*	Ap^r	Contains an *ADH* promoter that expresses LexA fused to the homeodomain of bicoid to produce nonactivating fusion; used as positive control for repression assay, negative control for activation and interaction assays
pSH17-4[e,f] (control)	*HIS3*	Ap^r	*ADH* promoter expresses LexA fused to GAL4 activation domain; used as a positive control for transcriptional activation
pMW101[f]	*HIS3*	Cm^r	Same as pEG202, but with altered antibiotic resistance markers; basic plasmid used for cloning bait
pMW103[f]	*HIS3*	Km^r	Same as pEG202, but with altered antibiotic resistance markers; basic plasmid used for cloning bait
pHybLex/Zeo[f,g]	Zeo^r	Zeo^r	Bait cloning vector compatible with interaction trap and all other two-hybrid systems; minimal ADH promotor expresses LexA followed by extended polylinker
Activation domain fusion plasmids			
pJG4-5[c,d,e,f]	TRP1	Ap^r	Contains a *GAL1* promoter that expresses nuclear localization domain, transcriptional activation domain, HA epitope tag, cloning sites; used to express cDNA libraries
pJG4-5I	*TRP1*	Ap^r	An integrating form of pJG4-5 that can be targeted into *TRP1* by digestion with *Bsu*36I (New England Biolabs); to be used with pEE202I to study interactions that occur physiologically at low protein concentrations
pYESTrp[g]	*TRP1*	Ap^r	Contains a *GAL1* promoter that expresses nuclear localization domain, transcriptional activation domain, V5 epitope tag, multiple cloning sites; contains f1 ori and T7 promoter/flanking site; used to express cDNA libraries (Invitrogen)
pMW102[f]	*TRP1*	Km^r	Same as pJG4-5, but with altered antibiotic resistance markers; no libraries yet available
pMW104[f]	*TRP1*	Cm^r	Same as pJG4-5, but with altered antibiotic resistance markers; no libraries yet available
LacZ reporter plasmids			
pSH18-34[d,e,f]	*URA3*	Ap^r	Contains 8 *LexA* operators that direct transcription of the *lacZ* gene; one of the most sensitive indicator plasmids for transcriptional activation
pJK103[e]	*URA3*	Ap^r	Contains two *LexA* operators that direct transcription of the *lacZ* gene; an intermediate reporter plasmid for transcriptional activation
pRB1840[e]	*URA3*	Ap^r	Contains 1 *LexA* operator that directs transcription of the *lacZ* gene; one of the most stringent reporters for transcriptional activation
pMW112[f]	*URA3*	Km^r	Same as pSH18-34, but with altered antibiotic resistance marker
pMW109[f]	*URA3*	Km^r	Same as pJK103, but with altered antibiotic resistance marker

Table 19.2.1 Interaction Trap Components[a,b], continued

Plasmid name/source	Selection		Comment/description
	In yeast	In *E. coli*	
pMW111[f]	*URA3*	Km^r	Same as pRB1840, but with altered antibiotic resistance marker
pMW107[f]	*URA3*	Cm^r	Same as pSH18-34, but with altered antibiotic resistance marker
pMW108[f]	*URA3*	Cm^r	Same as pJK103, but with altered antibiotic resistance marker
pMW110[f]	*URA3*	Cm^r	Same as pRB1840, but with altered antibiotic resistance marker
pJK101[e,f] (control)	*URA3*	Ap^r	Contains a *GAL1* upstream activating sequence followed by two *lexA* operators followed by *lacZ* gene; used in repression assay to assess bait binding to operator sequences

[a]All plasmids contain a 2μm origin for maintenance in yeast, as well as a bacterial origin of replication, except where noted (pEE202I, pJG4.5I).

[b]Interaction Trap reagents represent the work of many contributors: the original basic reagents were developed in the Brent laboratory (Gyuris et al., 1993). Plasmids with altered antibiotic resistance markers (all pMW plasmids) were constructed at Glaxo in Research Triangle Park, N.C. (Watson et al., 1996). Plasmids and strains for specialized applications have been developed by the following individuals: E. Golemis, Fox Chase Cancer Center, Philadelphia, Pa. (pEG202); J. Kamens, BASF, Worcester, Mass. (pJK202); cumulative efforts of I. York, Dana-Farber Cancer Center, Boston, Mass. and M. Sainz and S. Nottwehr, U. Oregon (pNLexA); D.A. Shaywitz, MIT Center for Cancer Research, Cambridge, Mass. (pGilda); R. Buckholz, Glaxo, Research Triangle Park, N.C. (pEE2021, pJG4-51); J. Gyuris, Mitotix, Cambridge, Mass. (pJG4-5); S. Hanes, Wadsworth Institute, Albany, N.Y. (pSH17-4); R.L. Finley, Wayne State University School of Medicine, Detroit, Mich. (pRFHM1); S. Hanes, Wadsworth Institute, Albany, N.Y. (pSH18-34); J. Kamens, BASF, Worcester, Mass. (pJK101, pJK103); R. Brent, Dept. of Molecular Biology, Massachusetts General Hospital, Boston, Mass. (pRB1840). Specialized plasmids not yet commercially available can be obtained by contacting the Brent laboratory at Massachusetts General Hospital, (617) 726-5925 or *brent@frodo.mgh.harvard.edu*, or the Golemis laboratory, (215) 728-2860 or *EA_Golemis@fccc.edu*.

[c]Sequence data are available for pEG202 (pLexA) accession number pending.

[d]Plasmids commercially available from Clontech and OriGene; for Clontech pEG202 is listed as pLexA, pJG4-5 as pB42AD, and pSH18-34 as p8op-LacZ.

[e]Plasmids and strains available from OriGene.

[f]In pMW plasmids the ampicillin resistance gene (Ap^r) is replaced with the chloramphenicol resistance gene (Cm^r) and the kanamycin resistance gene (Km^r) from pBC SK(+) and pBK-CMV (Stratagene), respectively. The choice between Km^r and Cm^r or Ap^r plasmids is a matter of personal taste; use of basic Ap^r plasmids is described in the basic protocols. Use of the more recently developed reagents would facilitate the purification of library plasmid in later steps by eliminating the need for passage through KC8 bacteria, with substantial saving of time and effort. Ap^r has been maintained as marker of choice for the library plasmid because of the existence of multiple libraries already possessing this marker. These plasmids are the basic set of plasmids recommended for use.

[g]Plasmids commercially available from Invitrogen as components of a Hybrid Hunter kit; this kit also includes all necessary positive and negative controls (not listed in this table). See Background Information for further details on commercially available reagents.

porter—the EGY48 strain (or related strain EGY191) that expresses the LexA fusion protein should not grow on medium lacking Leu, and the colonies should be white on medium containing Xgal. The characterized bait protein plasmid is used for Basic Protocol 2 to screen a library for interacting proteins.

Materials

DNA encoding the protein of interest

Plasmids (see Table 19.2.1): pEG202 (see Fig. 19.2.3), pSH18-34 (see Fig. 19.2.4), pSH17-4, pRFHM1, and pJK101 for basic characterization; other plasmids for specific circumstances as described (Clontech, Invitrogen, OriGene, or R. Brent)

Yeast strain EGY48 (*ura3 trp1 his3 3LexA*-operator-*LEU2*), or EGY191 (*ura3 trp1 his3 1LexA*-operator-*LEU2*; Table 19.2.2)

Complete minimal (CM) medium dropout plates (*APPENDIX 4L*), supplemented with 2% (w/v) of the indicated sugars (glucose or galactose), in 100-mm plates:
- Glu/CM, –Ura, –His
- Gal/CM, –Ura, –His
- Gal/CM, –Ura, –His, –Leu

Z buffer (*APPENDIX 4L*) with 1 mg/ml 5-bromo-4-chloro-3-indolyl-β-D-galactosidase (Xgal)

BOULDER CENTRAL UNIVERSITY LIBRARY

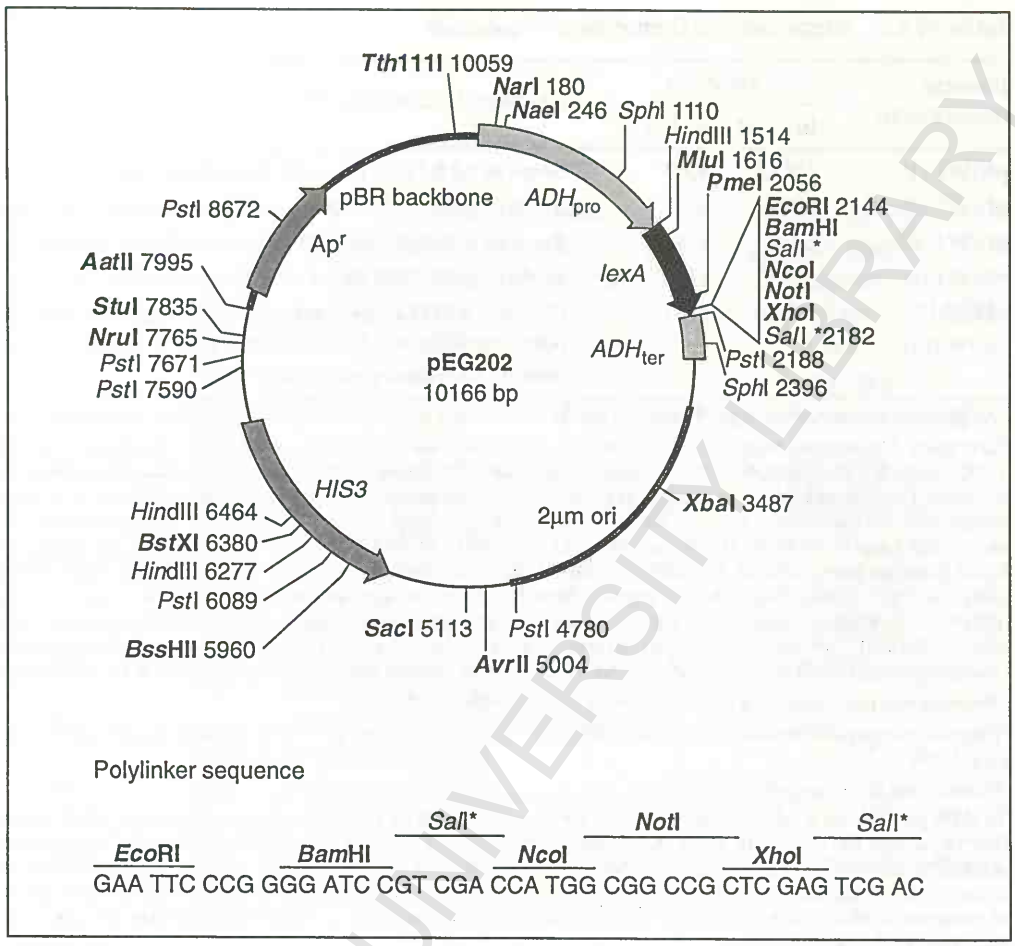

Figure 19.2.3 LexA-fusion plasmids: pEG202. The strong constitutive *ADH* promoter is used to express bait proteins as fusions to the DNA-binding protein LexA. Restriction sites shown in this map are based on recently compiled pEG202 sequence data and include selected sites suitable for diagnostic restriction endonuclease digests. A number of restriction sites are available for insertion of coding sequences to produce protein fusions with LexA; the polylinker sequence and reading frame relative to LexA are shown below the map with unique sites marked in bold type. The sequence 5′-CGT CAG CAG AGC TTC ACC ATT G-3′ can be used to design a primer to confirm correct reading frame for LexA fusions. Plasmids contain the *HIS3* selectable marker and the 2µm origin of replication to allow propagation in yeast, and the Ap^r antibiotic resistance gene and the pBR origin of replication to allow propagation in *E. coli*. In the recently developed LexA-expression plasmids pMW101 and pMW103, the ampicillin resistance gene (Ap^r) has been replaced with the chloramphenicol resistance gene (Cm^r) and the kanamycin resistance gene (Km^r), respectively (see Table 19.2.1 for details).

Gal/CM dropout liquid medium (*APPENDIX 4L*) supplemented with 2% Gal

Antibody to LexA or fusion domain: monoclonal antibody to LexA (Clontech, Invitrogen) or polyclonal antibody to LexA (available by request from R. Brent or E. Golemis)

H_2O, sterile

30°C incubator

Nylon membrane

Whatman 3MM filter paper

Additional reagents and equipment for subcloning DNA fragments (Struhl, 1987), lithium acetate transformation of yeast (*APPENDIX 4L*), liquid assay for β-galactosidase (*APPENDIX 4L*), preparation of protein extracts for immunoblot analysis (see Support Protocol 1), and immunoblotting and immunodetection (*UNIT 10.10*)

BCU IASI / CENTRAL UNIVERSITY LIBRARY

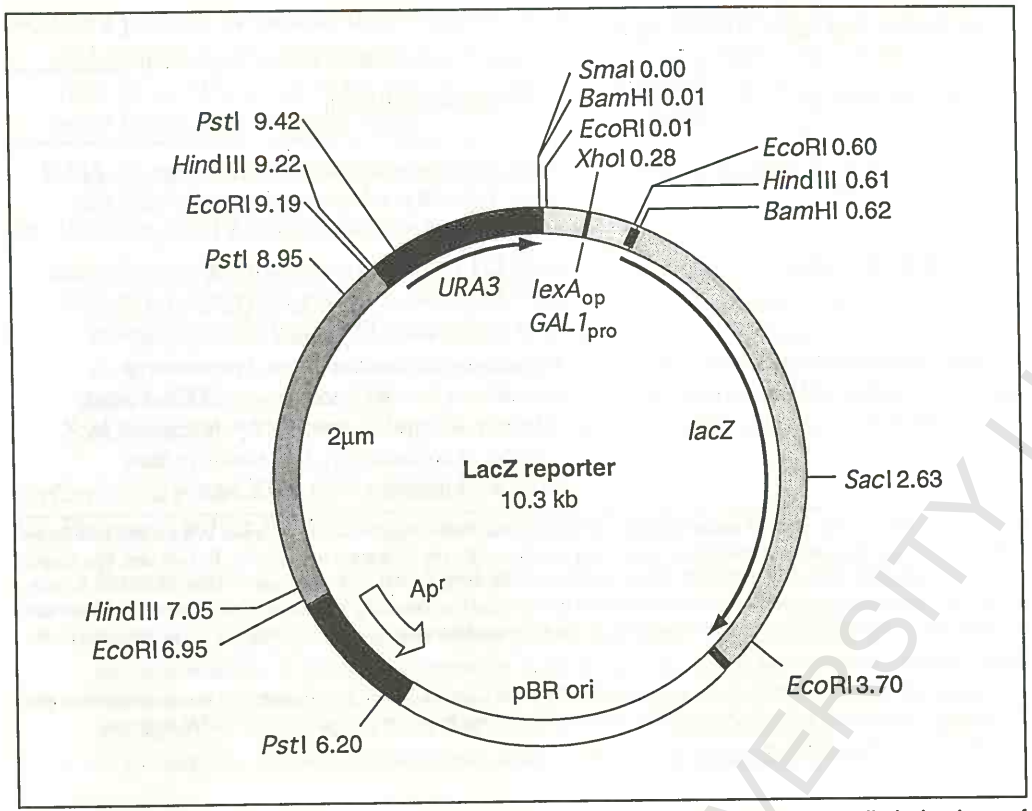

Figure 19.2.4 LacZ reporter plasmid. pRB1840, pJK103, and pSH18-34 are all derivatives of LR1Δ1 (West et al., 1984) containing eight, two, or one operator for LexA (*LexA*$_{op}$) binding inserted into the unique *Xho*I site located in the minimal *GAL1* promoter (*GAL1*$_{pro}$; 0.28 on map). The plasmid contains the *URA3* selectable marker, the 2µm origin to allow propagation in yeast, the ampicillin resistance (Ap^r) gene, and the pBR322 origin (ori) to allow propagation in *E. coli*. Numbers indicate relative map positions. In the recently developed derivatives, the ampicillin resistance gene (Ap^r) has been replaced with the chloramphenicol or kanamycin resistance genes (see Table 19.2.1 for details).

NOTE: All solutions and equipment coming into contact with cells must be sterile, and proper sterile technique should be used accordingly.

Transform yeast with the bait protein plasmid

1. Using standard subcloning techniques (e.g., Struhl, 1987), insert the DNA encoding the protein of interest into the polylinker of pEG202 (see Fig. 19.2.3) or other LexA fusion plasmid to make an in-frame protein fusion.

   The LexA fusion protein is expressed from the strong alcohol dehydrogenase (ADH) promoter. pEG202 also contains a HIS3 selectable marker and a 2µm origin for propagation in yeast. pEG202 with the DNA encoding the protein of interest inserted is designated pBait. Uses of alternative LexA fusion plasmids are described in Background Information.

2. Perform three separate lithium acetate transformations (*APPENDIX 4L*) of EGY48 using the following combinations of plasmids:

   pBait + pSH18-34 (test)
   pSH17-4 + pSH18-34 (positive control for activation)
   pRFHM1 + pSH18-34 (negative control for activation).

   Use of the two LexA fusions as positive and negative controls allows a rough assessment of the transcriptional activation profile of LexA bait proteins. pEG202 itself is not a good negative control because the peptide encoded by the uninterrupted polylinker sequences is itself capable of very weakly activating transcription.

BCU LIBRARY CENTRAL UNIVERSITY LIBRARY

Table 19.2.2 Interaction Trap Yeast Selection Strains[a]

Strain	Relevant genotype	Number of operators	Comments/description
EGY48[b,c,d]	*MATα trp1*, *his3*, *ura3*, lexAops-LEU2	6	*lexA* operators direct transcription from the *LEU2* gene; EGY48 is a basic strain used to select for interacting clones from a cDNA library
EGY191	*MATα trp1*, *his3*, *ura3*, lexAops-LEU2	2	EGY191 provides a more stringent selection than EGY48, producing lower background with baits with instrinsic ability to activate transcription
L40[c]	MATα *trpl*, *leu2*, *ade2*, GAL4, *lexAops-HIS34*, *lexAops-lacZ8*		Expression driven from *GAL1* promoter is constitutive in L40 (inducible in EGY strains); selection is for *HIS* prototrophy. Integrated *lacZ* reporter is considerably less sensitive than pSH18-34 maintained in EGY strains

[a]Interaction Trap reagents represent the work of many contributors: the original basic reagents were developed in the Brent laboratory (Gyuris et al., 1993). Strains for specialized applications have been developed by the following individuals: E. Golemis, Fox Chase Cancer Center, Philadelphia, Pa. (EGY48, EGY191); A.B. Vojtek and S.M. Hollenberg, Fred Hutchinson Cancer Research Center, Seattle, Wash. (L40). Specialized strains not yet commercially available can be obtained by contacting the Brent laboratory at The Molecular Sciences Institute, Berkeley, (510) 726-5990 or brent@molsci.org, or the Golemis laboratory, (215) 728-2860 or *EA_Golemis@fccc.edu.*

[b]Strains commercially available from Clontech.

[c]Strains commercially available from Invitrogen as components of a Hybrid Hunter kit; the kit also includes all necessary positive and negative controls (not listed in this table). See Background Information for further details on commercially available reagents.

[d]Strains commercially available from OriGene.

pSH18-34 contains a 2μm origin and a URA3 selectable marker for maintenance in yeast, as well as a bacterial origin of replication and ampicillin-resistance gene. It is the most sensitive lacZ reporter available and will detect any potential ability to activate lacZ transcription. pSH17-4 is a HIS3 2μm plasmid encoding LexA fused to the activation domain of the yeast activator protein GAL4. This fusion protein strongly activates transcription. pRFHM1 is a HIS3 2μm plasmid encoding LexA fused to the N-terminus of the Drosophila protein bicoid. This fusion protein has no ability to activate transcription.

3. Plate each transformation mixture on Glu/CM –Ura, –His dropout plates. Incubate 2 days at 30°C to select for yeast that contain both plasmids.

   Colonies obtained can be used simultaneously in tests for the activation of lacZ (steps 4 to 7) and LEU2 (steps 12 to 13) reporters.

Assay lacZ gene activation by β-galactosidase assay

4. Streak a Glu/CM –Ura, –His master dropout plate with at least five or six independent colonies obtained from each of the three transformations in step 3 (test, positive control, and negative control) and incubate overnight at 30°C.

   The filter assay described in Steps 5a to 7a (based on Breeden and Nasmyth, 1985) provides a rapid assay for β-galactosidase transcription. Alternatively, a liquid assay (APPENDIX 4L) or a plate assay (described in Steps 5b to 7b) may be used.

Perform filter assay for β-galactosidase activity:

5a. Lift colonies by gently placing a nylon membrane on the yeast plate and allowing it to become wet through. Remove the membrane and air dry 5 min. Chill the membrane, colony side up, 10 min at –70°C.

   Whatman 3MM filters can be cut to the size of the yeast plate as a more economical alternative to nylon membranes for performing lifts. In addition, two or three 5-min temperature cycles (–70°C to room temperature) can be used instead of a single cycle to promote better lysis; this may be worth doing if there is difficulty visualizing blue color.

BIBLIOTECA UNIVERSITARIA

6a. Cut a piece of Whatman 3MM filter paper slightly larger than the colony membrane and soak it in Z buffer containing 1 mg/ml Xgal. Place colony membrane, colony side up, on Whatman 3MM paper, or float it in the lid of a petri dish containing ~2 ml Z buffer with 1 mg/ml Xgal.

Acceptable results may be obtained using as little as 300 µg/ml Xgal.

7a. Incubate at 30°C and monitor for color changes.

It is generally useful to check the membrane after 20 min, and again after 2 to 3 hr. Strong activators will produce a blue color in 5 to 10 min, and a bait protein (LexA fusion protein) that does so is unsuitable for use in an interactor hunt using this lacZ reporter plasmid. Weak activators will produce a blue color in 1 to 6 hr (compare versus negative control pRFHMI which will itself produce a faint blue color with time) and may or may not be suitable. Weak activators should be tested using the repressor assay described in steps 8 to 11.

Perform Xgal plate assay for lacZ activation:

5b. Prepare Z buffer Xgal plates as described in APPENDIX 4L.

For activation assays, plates should be prepared with glucose as a sugar source. For repression assays (steps 8 to 11), galactose should be used as a sugar source. In our experience, when patching from a master plate to Xgal plates, sufficient yeast are transferred that plasmid loss is not a major problem even in the absence of selection; this is balanced by the desire to assay sets of constructs on the same plate to eliminate batch variation in Xgal potency. Hence, plates should be made either with complete minimal amino acid mix, or by dropping out only uracil (–Ura), to make the plates universally useful.

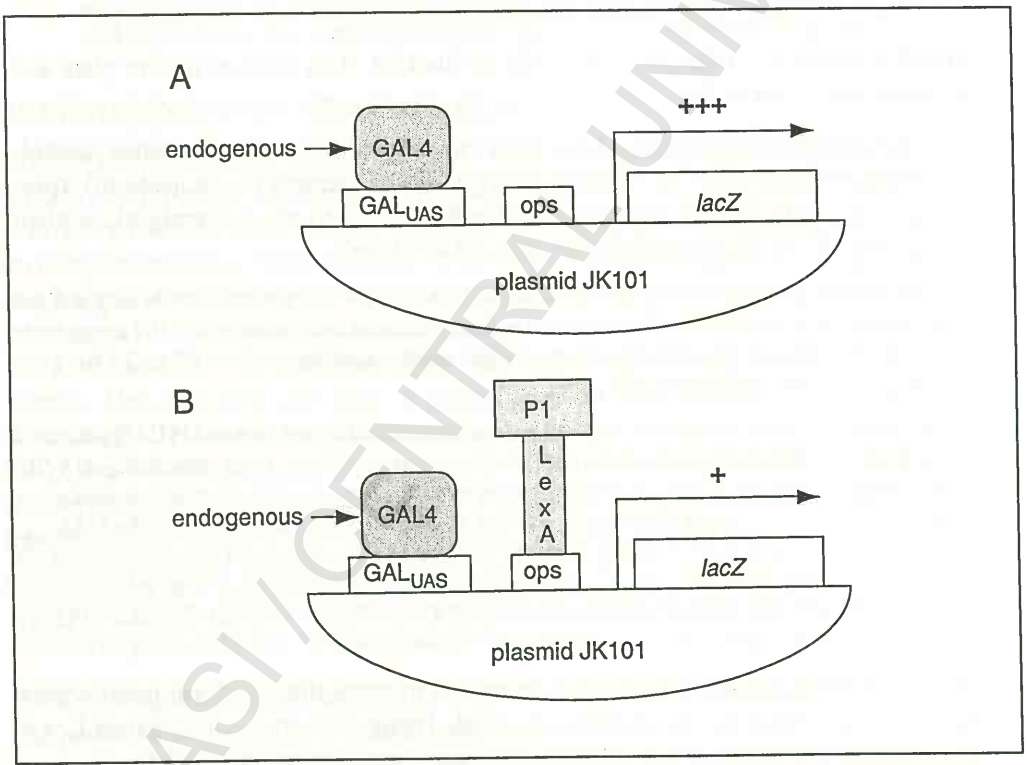

Figure 19.2.5 Repression assay for DNA binding. **(A)** The plasmid JK101 contains the upstream activating sequence (UAS) from the *GAL1* gene followed by *LexA* operators upstream of the *lacZ* coding sequence. Thus, yeast containing pJK101 will have significant β-galactosidase activity when grown on medium in which galactose is the sole carbon source because of binding of endogenous yeast GAL4 to the GAL_{UAS} **(B)**. LexA-fused proteins (P1-LexA) that are made, enter the nucleus, and bind the *LexA* operator sequences (ops) will block activation from the GAL_{UAS}, repressing β-galactosidase activity (+) 3- to 5-fold. On glucose/Xgal medium, yeast containing pJK101 should be white because GAL_{UAS} transcription is repressed.

B.C.U. „M. EMINESCU" IAŞI
CHIMIE

6b. Streak yeast from master plate to Xgal plate and incubate at 30°C.

7b. Examine plates for color development at intervals over the next 2 to 3 days.

Strongly activating fusions should be visibly blue on the plate within 12 to 24 hr; moderate activators will be visibly blue after ~2 days.

When a bait protein appreciably activates transcription under these conditions, there are several recourses. The first and simplest is to switch to a less sensitive lacZ reporter plasmid; use of pJK103 and pRB1840 may be sufficient to reduce background to manageable levels. If this fails to work, it is frequently possible to generate a truncated LexA fusion that does not activate transcription.

Confirm fusion-protein synthesis by repression assay

For LexA fusions that do not activate transcription, confirm by performing a repression assay (Brent and Ptashne, 1984) that the LexA fusion protein is being synthesized in yeast (some proteins are not) and that it is capable of binding *LexA* operator sequences (Fig. 19.2.5). The following steps can be performed concurrently with the activation assay.

8. Transform EGY48 yeast with the following combinations of plasmids (three transformations):

   pBait + pJK101 (test)
   pRFHM1 + pJK101 (positive control for repression)
   pJK101 alone (negative control for repression).

9. Plate each transformation mix on Glu/CM –Ura, –His dropout plates or Glu/CM –Ura dropout plates as appropriate to select yeast cells that contain the indicated plasmids. Incubate 2 to 3 days at 30°C until colonies appear.

10. Streak colonies to a Glu/CM –Ura, –His or Glu/CM –Ura dropout master plate and incubate overnight at 30°C.

11. Assay β-galactosidase activity of the three transformed strains (test, positive control, and negative control) by liquid assay (using Gal/CM dropout liquid medium), filter assay (steps 5a to 7a, first restreaking to Gal/CM plates to grow overnight), or plate assay (steps 5b to 7b, using Gal/CM –Ura XGal plates).

    This assay should not be run for more than 1 to 2 hr for membranes, or 36 hr for Xgal plates, as the high basal lacZ activity will make differential activation of pJK101 impossible to see with longer incubations. Use of Xgal plates, and inspection 12 to 24 hr after streaking, is generally most effective.

    The plasmid pJK101 contains the galactose upstream activating sequence (UAS) followed by LexA operators upstream of the lacZ coding sequence. Thus, yeast containing pJK101 will have significant β-galactosidase activity when grown on medium in which galactose is the sole carbon source because of binding of endogenous yeast GAL4 to the GAL_{UAS}. LexA-fused proteins that are made, enter the nucleus, and bind the LexA operator sequences block activation from the GAL_{UAS}, repressing β-galactosidase activity 3- to 20-fold. Note that on Glu/Xgal medium, yeast containing pJK101 should be white, because GAL_{UAS} transcription is repressed.

12. If a bait protein neither activates nor represses transcription, perform immunoblot analysis by probing an immunoblot of a crude lysate with antibodies against LexA or the fusion domain to test for protein synthesis (see Support Protocol 1).

    Even if a bait protein represses transcription, it is generally a good idea to assay for the production of full-length LexA fusions, as occasionally some fusion proteins will be proteolytically cleaved by endogenous yeast proteases. If the protein is made but does not repress, it may be necessary to clone the sequence into a LexA fusion vector that contains a nuclear localization motif, e.g., pJK202 (see Table 19.2.1), or to modify or truncate the fusion domain to remove motifs that target it to other cellular compartments (e.g., myristoylation signals).

BIU IASI / CENTRAL UNIVERSITY LIBRARY

Test for Leu requirement

These steps can be performed concurrently with the *lacZ* activation and repression assays.

13. Disperse a colony of EGY48 containing pBait and pSH18-34 reporter plasmids into 500 µl sterile water. Dilute 100 µl of suspension into 1 ml sterile water. Make a series of 1/10 dilutions in sterile water to cover a 1000-fold concentration range.

14. Plate 100 µl from each tube (undiluted, 1/10, 1/100, and 1/1000) on Gal/CM –Ura, –His dropout plates and on Gal/CM –Ura, –His, –Leu dropout plates. Incubate overnight at 30°C.

There will be a total of eight plates. Gal/CM –Ura, –His dropout plates should show a concentration range from 10 to 10,000 colonies and Gal/CM –Ura, –His, –Leu dropout plates should have no colonies.

Actual selection in the interactor hunt is based on the ability of the bait protein and acid-fusion pair, but not the bait protein alone, to activate transcription of the LexA operator-LEU2 gene and allow growth on medium lacking Leu. Thus, the test for the Leu requirement is the most important test of whether the bait protein is likely to have an unworkably high background. The LEU2 reporter in EGY48 is more sensitive than the pSH18-34 reporter for some baits, so it is possible that a bait protein that gives little or no signal in a β-galactosidase assay would nevertheless permit some level of growth on –Leu medium. If this occurs, there are several options for proceeding, the most immediate of which is to substitute EGY191 (see Table 19.2.2), a less sensitive screening strain, and repeat the assay.

As outlined in this protocol, the authors recommend the strategy of performing the initial screening using the most sensitive reporters and then, if activation is detected, screening with increasingly less sensitive reporters (see Critical Parameters for further discussion).

PERFORMING AN INTERACTOR HUNT

BASIC PROTOCOL 2

An interactor hunt involves two successive large platings of yeast containing LexA-fused probes and reporters and libraries in pJG4-5 (Fig. 19.2.6, Table 19.2.3) with a cDNA expression cassette under control of the *GAL* promoter. In the first plating, yeast are plated on complete minimal (CM) medium –Ura, –His, –Trp dropout plates with glucose (Glu) as a sugar source to select for the library plasmid. In the second plating, which selects for yeast that contain interacting proteins, a slurry of primary transformants is plated on CM –Ura, –His, –Trp, –Leu dropout plates with galactose/raffinose (Gal/Raff) as the sugar source. This two-step selection is encouraged for two reasons. First, a number of interesting cDNA-encoded proteins may be deleterious to the growth of yeast that bear them; these would be competed out in an initial mass plating. Second, it seems likely that immediately after simultaneous transformation and Gal induction, yeast bearing particular interacting proteins may not be able to initially express sufficient levels of these proteins to support growth on medium lacking Leu. Library plasmids from colonies identified in the second plating are purified by bacterial transformation and used to transform yeast cells for the final specificity screen.

A list of libraries currently available for use with this system is provided in Table 19.2.3. The protocol outlined below describes the steps used to perform a single-step screen that should saturate a library derived from a mammalian cell. For screens with libraries derived from lower eukaryotes with less complex genomes, fewer plates will be required.

Occasionally, baits that seemed well-behaved during preliminary tests produce unworkably high backgrounds of "positives" during an actual screen (see Background Information and Critical Parameters). To forestall the waste of time and materials performing a screen with such a bait would entail, an alternative approach is to perform a scaled-back

BOSTON BIOMEDICAL RESEARCH INSTITUTE LIBRARY

screen when working with a new bait (e.g., 5 rather than 30 plates of primary transformants). The results can be assessed before doing a full screen; it is then possible to switch to lower-sensitivity reporter strains and plasmids, if appropriate. Although individual baits will vary, the authors' current default preference is to use the *lacZ* reporter pJK103 in conjunction with either EGY48 or EGY191. Polymerase chain reaction (PCR) can also be used in a rapid screening approach that may be preferable if a large number of positions are obtained in a library screen (see Alternate Protocol 1).

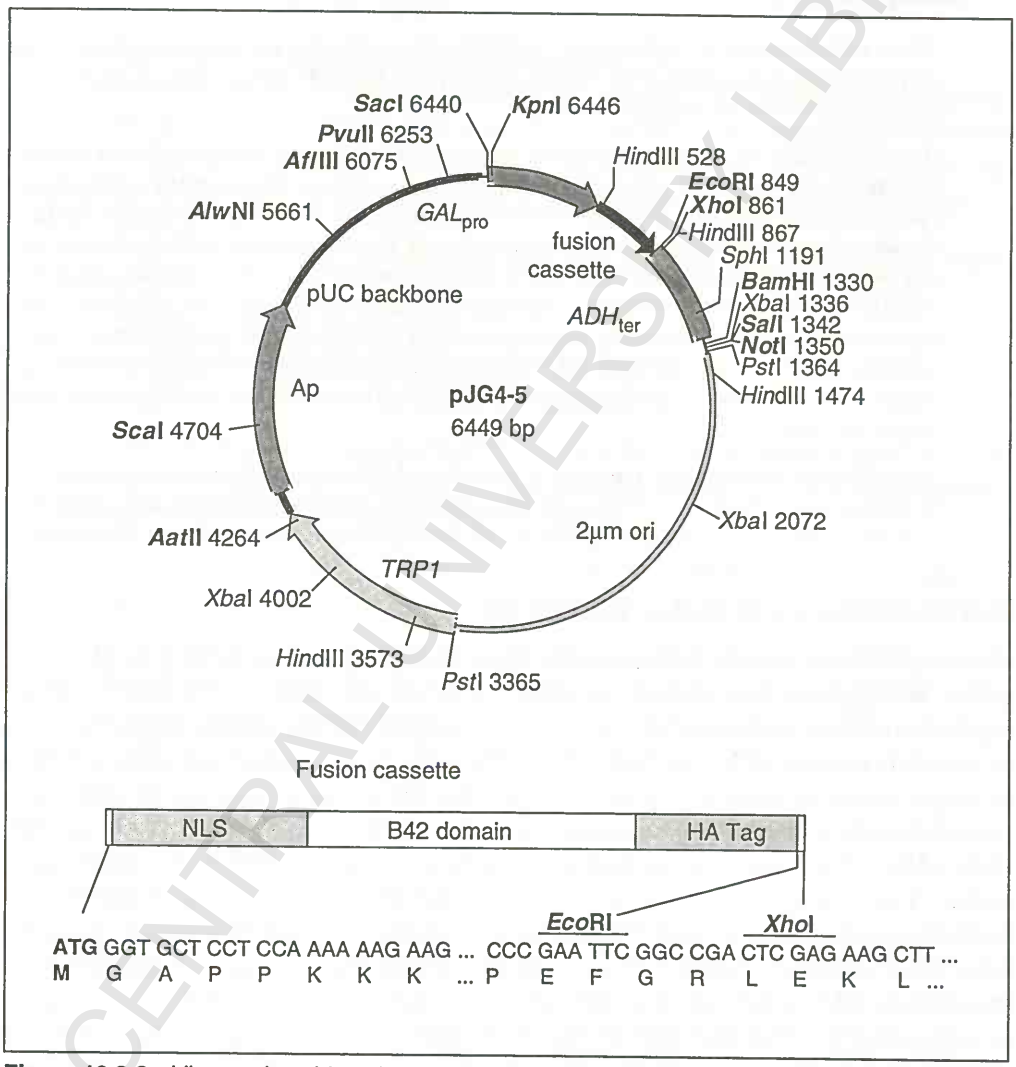

Figure 19.2.6 Library plasmids: pJG4-5. Library plasmids express cDNAs or other coding sequences inserted into unique *Eco*RI and *Xho*I sites as a translational fusion to a cassette consisting of the SV40 nuclear localization sequence (NLS; PPKKKRKVA), the acid blob B42 domain (Ruden et al, 1991), and the hemagglutinin (HA) epitope tag (YPYDVPDYA). Expression of cassette sequences is under the control of the *GAL1* galactose-inducible promoter. This map is based on the sequence data available for pJG4-5, and includes selected sites suitable for diagnostic restriction digests (shown in bold). The sequence 5′-CTG AGT GGA GAT GCC TCC-3′ can be used as a primer to identify inserts or to confirm correct reading frame. The pJG4-5 plasmid contains the *TRP1* selectable marker and the 2µm origin to allow propagation in yeast, and the antibiotic resistance gene and the pUC origin to allow propagation in *E. coli.* In the recently developed pJG4-5 derivative plasmids pMW104 and pMW102, the ampicillin resistance gene (Ap^r) has been replaced with the chloramphenicol resistance gene (Cm^r) and the kanamycin resistance gene (Km^r), respectively (see Table 19.2.2 for details). Currently existing libraries are all made in the pJG4-5 plasmid (Gyuris et al., 1993) shown on this figure. Unique sites are marked in bold type.

BAU IASH CENTRAL UNIVERSITY LIBRARY

Materials

Yeast containing appropriate combinations of plasmids (see Table 19.2.1 and Table 19.2.2):
- EGY48 containing *LexA*-operator-*lacZ* reporter and pBait (see Basic Protocol 1)
- EGY48 containing *LexA*-operator-*lacZ* reporter and pRFHM-1
- EGY48 containing *LexA*-operator-*lacZ* reporter and any nonspecific bait

Complete minimal (CM) dropout liquid medium (*APPENDIX 4L*) supplemented with sugars (glucose, galactose, and/or raffinose) as indicated [2% (w/v) Glu, or 2% (w/v) Gal + 1% (w/v) Raff]:
- Glu/CM –Ura, –His
- Glu/CM –Trp
- Gal/Raff/CM –Ura, –His, –Trp

H_2O, sterile

TE buffer (pH 7.5; *APPENDIX 2E*)/0.1 M lithium acetate

Library DNA in pJG4-5 (Table 19.2.3 and Fig. 19.2.6)

High-quality sheared salmon sperm DNA (see Support Protocol 2)

40% (w/v) polyethylene glycol 4000 (PEG 4000; filter sterilized)/0.1 M lithium acetate/TE buffer (pH 7.5)

Dimethyl sulfoxide (DMSO)

Complete minimal (CM) medium dropout plates (*APPENDIX 4L*) supplemented with sugars and Xgal (20 µg/ml) as indicated [2% (w/v) Glu, and 2% (w/v) Gal + 1% (w/v) Raff]:
- Glu/CM –Ura, –His, –Trp, 24 × 24–cm (Nunc) and 100-mm
- Gal/Raff/CM –Ura, –His, –Trp, 100-mm
- Gal/Raff/CM –Ura, –His, –Trp, –Leu, 100-mm
- Glu/Xgal/CM –Ura, –His, –Trp, 100-mm
- Gal/Raff/Xgal/CM –Ura, –His, –Trp, 100-mm
- Glu/CM –Ura, –His, –Trp, –Leu, 100-mm
- Glu/CM –Ura, –His, 100-mm
- Gal/CM –Ura, –His, –Trp, –Leu, 100-mm

TE buffer (pH 7.5), sterile (optional)

Glycerol solution (see recipe)

E. coli KC8 (*pyrF leuB600 trpC hisB463*; constructed by K. Struhl and available from R. Brent)

LB/ampicillin plates (*APPENDIX 4A*)

E. coli DH5α or other strain suitable for preparation of DNA for sequencing

Bacterial defined minimal A medium plates: 1× A medium plates containing 0.5 µg/ml vitamin B1 (*APPENDIX 4A*) and supplemented with 40 µg/ml each Ura, His, and Leu

30°C incubator, with and without shaking

Low-speed centrifuge and rotor

50-ml conical tubes, sterile

1.5-ml microcentrifuge tubes, sterile

42°C heating block

Glass microscope slides, sterile

Additional reagents and equipment for rapid miniprep isolation of yeast DNA (*APPENDIX 4L*), transformation of bacteria by electroporation (*UNIT 5.10*), miniprep isolation of bacterial DNA (*APPENDIX 4C*), restriction endonuclease digestion (*APPENDIX 4I*; optional), and agarose gel electrophoresis (*APPENDIX 4F*; optional)

NOTE: All solutions and equipment coming into contact with cells must be sterile, and proper sterile technique should be used accordingly.

[a]Most libraries are constructed in either the pJG4-5 vector or the pYESTrp vector (JG or Y in the Vector column); the peptide aptamer library is made in the pJM-1 vector. Libraries available from the public domain were constructed by the following individuals: (1) J. Gyuris; (3) C. Sardet and J. Gyuris; (4) W. Kolanus, J. Gyuris, and B. Seed; (39) D. Krainc; (50-52) R. Finley; (55) P. Watt; (54) P. Colas, B. Cohen, T. Jessen, I. Grishina, J. McCoy, and R. Brent (Colas et al., 1996). All libraries mentioned above were constructed in conjunction with and are available from the laboratory of Roger Brent, (617) 726-5925 or *brent@frodo.mgh.harvard.edu*. The following individual investigators must be contacted directly: (18) J. Pugh, Fox Chase Cancer Center, Philadelphia, Pa.; (8,9) Vinyaka Prasad, Albert Einstein Medical Center New York, N.Y.; (57, 58) Gregory B. Martin, *gmartin@dept.agry.purdue.edu*; (11) Huifeng Niu, *hn34@columbia.edu*; (16) Christer Hoog, *christer.hoog@cmb.ki.se*; (12) Kurt Gustin, *kgus@umich.edu*; (6) Stephan Witte, *Stephan.Witte@nimbus.rz.uni-konstanz.de*.

[b]Insert size ranges for pJG4-5 based libraries originally constructed in the Brent laboratory, which are now commercially available from Clontech, were reestimated by the company.

Transform the library

1. Grow an ~20-ml culture of EGY48 or EGY191 containing a *LexA*-operator-*lacZ* reporter plasmid and pBait in Glu/CM –Ura, –His liquid dropout medium overnight at 30°C.

   For best results, the pBait and lacZ reporter plasmids should have been transformed into the yeast within ~7 to 10 days of commencing a screen.

2. In the morning, dilute culture into 300 ml Glu/CM –Ura, –His liquid dropout medium to 2×10^6 cell/ml (OD_{600} = ~0.10). Incubate at 30°C until the culture contains ~1×10^7 cells/ml (OD_{600} = ~0.50).

3. Centrifuge 5 min at 1000 to 1500 × *g* in a low-speed centrifuge at room temperature to harvest cells. Resuspend in 30 ml sterile water and transfer to 50-ml conical tube.

4. Centrifuge 5 min at 1000 to 1500 × *g*. Decant supernatant and resuspend cells in 1.5 ml TE buffer/0.1 M lithium acetate.

5. Add 1 µg library DNA in pJG4-5 and 50 µg high-quality sheared salmon sperm carrier DNA to each of 30 sterile 1.5-ml microcentrifuge tubes. Add 50 µl of the resuspended yeast solution from step 4 to each tube.

   The total volume of library and salmon sperm DNA added should be <20 µl and preferably <10 µl.

   A typical library transformation will result in 2 to 3 × 10^6 primary transformants. Assuming a transformation efficiency of 10^5/µg library DNA, this transformation requires a total of 20 to 30 µg library DNA and 1 to 2 mg carrier DNA. Doing transformations in small aliquots helps reduce the likelihood of contamination, and for reasons that are not clear, provides significantly better transformation efficiency than scaled-up versions.

   Do not use excess transforming library DNA per aliquot of competent yeast cells because each competent cell may take up multiple library plasmids, complicating subsequent analysis.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

6. Add 300 µl of sterile 40% PEG 4000/0.1 M lithium acetate/TE buffer, pH 7.5, and invert to mix thoroughly. Incubate 30 min at 30°C.

7. Add DMSO to 10% (~40 µl per tube) and invert to mix. Heat shock 10 min in 42°C heating block.

8a. *For 28 tubes:* Plate the complete contents of one tube per 24 × 24–cm Glu/CM –Ura, –His, –Trp dropout plate and incubate at 30°C.

8b. *For two remaining tubes:* Plate 360 µl of each tube on 24 × 24–cm Glu/CM –Ura, –His, –Trp dropout plate. Use the remaining 40 µl from each tube to make a series of 1/10 dilutions in sterile water. Plate dilutions on 100-mm Glu/CM –Ura, –His, –Trp dropout plates. Incubate all plates 2 to 3 days at 30°C until colonies appear.

The dilution series gives an idea of the transformation efficiency and allows an accurate estimation of the number of transformants obtained.

Collect primary transformant cells

Conventional replica plating (Treco and Winston, 1992) does not work well in the selection process because so many cells are transferred to new plates that very high background levels inevitably occur. Instead, the procedure described below creates a slurry in which cells derived from $>10^6$ primary transformants are homogeneously dispersed. A precalculated number of these cells is plated for each primary transformant.

9. Cool all of the 24 × 24–cm plates containing transformants for several hours at 4°C to harden agar.

10. Wearing gloves and using a sterile glass microscope slide, gently scrape yeast cells off the plate. Pool cells from the 30 plates into one or two sterile 50-ml conical tubes.

This is the step where contamination is most likely to occur. Be careful.

11. Wash cells by adding a volume of sterile TE buffer or water at least equal to the volume of the transferred cells. Centrifuge ~5 min at 1000 to 1500 × *g*, room temperature, and discard supernatant. Repeat wash.

After the second wash, pellet volume should be ~25 ml cells derived from 1.5×10^6 transformants.

12. Resuspend pellet in 1 vol glycerol solution, mix well, and store up to 1 year in 1-ml aliquots at –70°C.

Determine replating efficiency

13. Remove an aliquot of frozen transformed yeast and dilute 1/10 with Gal/Raff/CM –Ura, –His, –Trp dropout medium. Incubate with shaking 4 hr at 30°C to induce the *GAL* promoter on the library.

Raffinose (Raff) aids in growth without diminishing transcription from the GAL1 promoter.

14. Make serial dilutions of the yeast cells using the Gal/Raff/CM –Ura, –His, –Trp dropout medium. Plate on 100-mm Gal/Raff/CM –Ura, –His, –Trp dropout plates and incubate 2 to 3 days at 30°C until colonies are visible.

15. Count colonies and determine the number of colony-forming units (cfu) per aliquot of transformed yeast.

In calculating yeast concentrations, it is useful to remember that 1 OD_{600} unit = $\sim 2.0 \times 10^7$ yeast cells. In general, if the harvest is done carefully, viability will be greater than 90%. Some intrepid investigators perform this step simultaneously with plating out on Leu selective medium (steps 16 and 17).

BCU JAN SENTRAL UNIVERSITY LIBRARY

Screen for interacting proteins

16. Thaw the appropriate quantity of transformed yeast based on the plating efficiency, dilute, and incubate as in step 13. Dilute cultures in Gal/Raff/CM –Ura, –His, –Trp, –Leu medium as necessary to obtain a concentration of 10^7 cells/ml (OD_{600} = ~0.5), and plate 100 µl on each of as many 100-mm Gal/Raff/CM –Ura, –His, –Trp, –Leu dropout plates as are necessary for full representation of transformants. Incubate 2 to 3 days at 30°C until colonies appear.

    Because not all cells that contain interacting proteins plate at 100% efficiency on –Leu medium (Estojak et al., 1995), it is desirable that for actual selection, each primary colony obtained from the transformation be represented on the selection plate by three to ten individual yeast cells. This will in some cases lead to multiple isolations of the same cDNA; however, because the slurry is not perfectly homogenous, it will increase the likelihood that all primary transformants are represented by at least one cell on the selective plate.

    It is easiest to visually scan for Leu$^+$ colonies using cells plated at ~10^6 cfu per 100-mm plate. Plating at higher density can contribute to cross-feeding between yeast, resulting in spurious background growth. Thus, for a transformation in which 3×10^6 colonies are obtained, plate ~2×10^7 cells on a total of 20 selective plates.

17. Carefully pick appropriate colonies to a new Gal/Raff/CM –Ura, –His, –Trp, –Leu master dropout plate. Incubate 2 to 7 days at 30°C until colonies appear.

    A good strategy is to pick a master plate with colonies obtained on day 2, a second master plate (or set of plates) with colonies obtained on day 3, and a third with colonies obtained on day 4. Colonies from day 2 and 3 master plates should generally be characterized further. If many apparent positives are obtained, it may be worth making master plates of the much larger number of colonies likely to be obtained at day 4 (and after). See Critical Parameters and annotation to step 19 for additional information about appropriate colony selection for the master plate.

    If no colonies appear within a week, those arising at later time points are likely to be artifactual. Contamination that has occurred at an earlier step (e.g., during plate scraping) is generally reflected by the growth of a very large number of colonies (>500/plate) within 24 to 48 hr after plating on selective medium.

    Some investigators omit use of a Gal/Raff/CM –Ura, –His, –Trp, –Leu master plate, restreaking directly to a Glu/CM –Ura, –His, –Trp master plate as in step 19.

Test for Gal dependence

The following steps test for Gal dependence of the Leu$^+$ insert and lacZ phenotypes to confirm that they are attributable to expression of the library-encoded proteins. The *GAL1* promoter is turned off and –Leu selection eliminated before reinducing.

18. Restreak from the Gal/Raff/CM –Ura, –His, –Trp, –Leu master dropout plate to a 100-mm Glu/CM –Ura, –His, –Trp master dropout plate. Incubate overnight at 30°C until colonies form.

19. Restreak or replica plate from this plate to the following plates:

    Glu/Xgal/CM –Ura, –His, –Trp
    Gal/Raff/Xgal/CM –Ura, –His, –Trp
    Glu/CM –Ura, –His, –Trp, –Leu
    Gal/Raff/CM –Ura, –His, –Trp, –Leu.

    At this juncture, colonies and the library plasmids they contain are tentatively considered positive if they are blue on Gal/Raff/Xgal plates but not blue or only faintly blue on Glu/Xgal plates, and if they grow on Gal/Raff/CM –Leu plates but not on Glu/CM –Leu plates.

    The number of positives obtained will vary drastically from bait to bait. How they are processed subsequently will depend on the number initially obtained and on the preference

BAU IASI / CENTRAL UNIVERSITY LIBRARY

of the individual investigator. If none are obtained using EGY48 as reporter strain, it may be worth attempting to screen a library from an additional tissue source. If a relatively small number (≤30) are obtained, proceed to step 20. However, sometimes searches will yield large numbers of colonies (>30 to 300, or more). In this case, there are several options. The first option is to warehouse the majority of the positives and work up the first 30 that arise; those growing fastest are frequently the strongest interactors. These can be checked for specificity, and restriction digests can be used to establish whether they are all independent cDNAs or represent multiple isolates of the same, or a small number, of cDNAs. If the former is true, it may be advisable to repeat the screen in a less sensitive strain background, as obtaining many different interactors can be a sign of low-affinity nonspecific background. Alternatively, if initial indications are that a few cDNAs are dominating the positives obtained, it may be useful to perform a filter hybridization with yeast (see Support Protocol 3) using these cDNAs as a probe to establish the frequency of their identification and exclude future reisolation of these plasmids. The second major option is to work up large numbers of positives to get a complete profile of isolated interactors (see Support Protocol 4). A third option is to temporarily warehouse the entire results of this first screen, and repeat the screen with a less sensitive strain such as EGY191, on the theory that it is most important to get stronger interactors first and a complete profile of interactors later. Finally, some investigators prefer to work up the entire set of positives initially obtained, even if such positives number in the hundreds. Particularly in this latter case, it is most effective to use Alternate Protocol 1 as a means to identify unique versus common positives.

Isolate plasmid from positive colonies by transfer into E. coli

20a. Transfer yeast plasmids directly into *E. coli* by following the protocol for direct electroporation (*UNIT 5.10*). Proceed to step 22.

20b. Isolate plasmid DNA from yeast by the rapid miniprep protocol (*APPENDIX 4C*) with the following alteration: after obtaining aqueous phase, precipitate by adding sodium acetate to 0.3 M final and 2 vol ethanol, incubate 20 min on ice, microcentrifuge 15 min at maximum speed, wash pellet with 70% ethanol, dry, and resuspend in 5 µl TE buffer.

Cultures can be grown prior to the miniprep using Glu/CM –Trp to select only for the library plasmid; this may increase the proportion of bacterial colonies that contain the desired plasmid.

21. Use 1 µl DNA to electroporate (*UNIT 5.10*) into competent KC8 bacteria, and plate on LB/ampicillin plates. Incubate overnight at 37°C.

Electroporation must be used to obtain transformants with KC8 because the strain is generally refractory to transformation.

22. Restreak or replica plate colonies arising on LB/ampicillin plates to bacterial defined minimal A medium plates containing vitamin B1 and supplemented with Ura, His, and Leu but lacking Trp. Incubate overnight at 37°C.

Colonies that grow under these conditions contain the library plasmid.

The yeast TRP1 gene can successfully complement the bacterial trpC-9830 mutation, allowing the library plasmid to be easily distinguished from the other two plasmids contained in the yeast. It is helpful to first plate transformations on LB/ampicillin plates, which provides a less stringent selection, followed by restreaking to bacterial minimal medium to maximize the number of colonies obtained (E.G., unpub. observ.).

23. Purify library-containing plasmids using a bacterial miniprep procedure (*APPENDIX 4C*).

Some investigators are tempted to immediately sequence DNAs obtained at this stage. At this point, it is still possible that none of the isolated clones will express bona fide

BOULDER/CENTRAL UNIVERSITY LIBRARY

interactors, and it is suggested that the following specificity tests be completed before committing the effort to sequencing (also see annotation to step 28).

Because multiple 2μm plasmids with the same marker can be simultaneously tolerated in yeast, it sometimes happens that a single yeast will contain two or more different library plasmids, only one of which encodes an interacting protein. The frequency of this occurrence varies in the hands of different investigators and may in some cases account for disappearing positives if the wrong cDNA is picked. When choosing colonies to miniprep, it is generally useful to work up at least two individual bacterial transformants for each yeast positive. These minipreps can then be restriction digested (APPENDIX 4I) with EcoRI + XhoI to release cDNA inserts, and the size of inserts determined on an agarose minigel (APPENDIX 4F) to confirm that both plasmids contain the same insert. An additional benefit of analyzing insert size is that it may provide some indication as to whether repeated isolation of the same cDNA is occurring, generally a good indication concerning the biological relevance of the interactor. See Background Information for further discussion.

Assess positive colonies with specificity tests

Much spurious background will have been removed by the previous series of controls. Other classes of false positives can be eliminated by retransforming purified plasmids into "virgin" *LexA*-operator-*LEU2*/*LexA*-operator-*lacZ*/pBait–containing strains that have not been subjected to Leu selection and verifying that interaction-dependent phenotypes are still observed. Such false positives could include mutations in the initial EGY48 yeast that favor growth on Gal medium, library-encoded cDNAs that interact with the LexA DNA-binding domain, or proteins that are sticky and interact with multiple biologically unrelated fusion domains.

24. In separate transformations, use purified plasmids from step 23 to transform yeast that already contain the following plasmids and are growing on Glu/CM –Ura, –His plates:

    EGY48 containing pSH18-34 and pBait
    EGY48 containing pSH18-34 and pRFHM-1
    EGY48 containing pSH18-34 and a nonspecific bait (optional).

25. Plate each transformation mix on Glu/CM –Ura, –His, –Trp dropout plates and incubate 2 to 3 days at 30°C until colonies appear.

26. Create a Glu/CM –Ura, –His, –Trp master dropout plate for each library plasmid being tested. Streak adjacently five or six independent colonies derived from each of the transformation plates. Incubate overnight at 30°C.

27. Restreak or replica plate from this master dropout plate to the same series of test plates used for the actual screen:

    Glu/Xgal/CM –Ura, –His, –Trp
    Gal/Raff/Xgal/CM –Ura, –His, –Trp
    Glu/CM –Ura, –His, –Trp, –Leu
    Gal/CM –Ura, –His, –Trp, –Leu.

True positive cDNAs should make cells blue on Gal/Raff/Xgal but not on Glu/Xgal plates, and should make them grow on Gal/Raff/CM –Leu but not Glu/CM –Leu dropout plates only if the cells contain LexA-bait. cDNAs that meet such criteria are ready to be sequenced (see legend to Fig. 19.2.3 for primer sequence) or otherwise characterized. Those cDNAs that also encode proteins that interact with either RFHM-1 or another nonspecific bait should be discarded.

It may be helpful to cross-check the isolated cDNAs with a database of cDNAs thought to be false positives. This database is available on the World Wide Web as a work in progress at http://www.fccc.edu:80/research/labs/golemis/InteractionTrapInWork.html. cDNAs reported to this database are generally those isolated only once in a screen in which obviously

BJU IASI / CENTRAL UNIVERSITY LIBRARY

true interactive partners were isolated multiple times, cDNAs that may interact with more than one bait, or cDNAs for which the interaction does not appear to make biological sense in the context of the starting bait. Although some proteins in this database may ultimately turn out in fact to associate with the bait that isolated them, they are by default unlikely to possess a unique and interesting function in the context of that bait if they are well represented in the database.

28. If appropriate, conduct additional specificity tests (see Support Protocol 5). Analyze and sequence positive isolates.

The primer sequence for use with pJG4-5 is provided in the legend to Figure 19.2.4.

DNA prepared from KC8 is generally unsuitable for dideoxy or automated sequencing even after use of Qiagen columns and/or cesium chloride gradients. Library plasmids to be sequenced should be retransformed from the KC8 miniprep stock (step 23) to a more amenable strain, such as DH5α, before sequencing is attempted.

RAPID SCREEN FOR INTERACTION TRAP POSITIVES

ALTERNATE PROTOCOL 1

Under some circumstances, it may be desirable to attempt the analysis of a large number of positives resulting from a two-hybrid screen. One such hypothetical example would be a bait with a leucine zipper or coiled coil known to dimerize with partner "A" that is highly expressed. In order to identify the rare novel partner "B", it is necessary to work through the high background of "A" reisolates. This protocol uses the polymerase chain reaction (PCR) in a strategy to sort positives into redundant (multiple isolates) and unique classes prior to plasmid rescue from yeast, thus greatly reducing the number of plasmid isolations that must be performed. An additional benefit is that this protocol preidentifies positive clones containing one or multiple library plasmids; for those containing only one library plasmid, only a single colony needs to be prepared through KC8/DH5α.

Additional Materials (also see Basic Protocol 2)

Yeast plated on Glu/CM –Ura, –His, –Trp master plate (see Basic Protocol 2, step 19)
Lysis solution (see recipe)
10 μM forward primer (FP1): 5′-CGT AGT GGA GAT GCC TCC-3′
10 μM reverse primer (FP2): 5′-CTG GCA AGG TAG ACA AGC CG-3′

Toothpicks or bacterial inoculating loops (*APPENDIX 4A*), sterile
96-well microtiter plate
Sealing tape, e.g., wide transparent tape
150- to 212-μm glass beads, acid-washed
Vortexer with flat plate

Additional reagents and equipment for performing an interactor hunt (see Basic Protocol 2), PCR amplification of DNA (*APPENDIX 4J*), agarose gel electrophoresis (*APPENDIX 4F*), restriction endonuclease digestion (*APPENDIX 4I*), electroporation (*UNIT 5.10*), and miniprep isolation of bacterial DNA (*APPENDIX 4C*)

1. Perform an interactor hunt (see Basic Protocol 2, steps 1 to 19).
2. Use a sterile toothpick or bacterial inoculating loop to transfer yeast from the Glu/CM, –Ura, –His, –Trp master plate into 25 μl lysis solution in a 96-well microtiter plate. Seal the wells of the microtiter plate with sealing tape and incubate 1.5 to 3.5 hr at 37°C with shaking.

The volume of yeast transferred should not exceed ~2 to 3 μl of packed pellet; larger quantities of yeast will reduce quality of the DNA. DNA can be efficiently recovered from master plates that have been stored up to 1 week at 4°C. If yeast have been previously

BCU ASTON CENTRAL UNIVERSITY LIBRARY

gridded on master plates, transfer to microtiter plates can be facilitated by using a multicolony replicator.

3. Remove tape from the plate, add ~25 µl acid-washed glass beads to each well, and reseal with the same tape. Firmly attach the microtiter plate to a flat-top vortexer, and vortex 5 min at medium-high power.

   The microtiter plate can be attached to the vortexer using 0.25-in (0.64-cm) rubber bands.

4. Remove the tape and add ~100 µl sterile water to each well. Swirl gently to mix, then remove sample for step 5. Press the tape back firmly to seal the microtiter plate and place in the freezer at –20°C for storage.

5. Amplify 0.8 to 2.0 µl of sample by standard PCR (*APPENDIX 4J*) in a ~30-µl volume using 3 µl each of the forward primer FP1 and the reverse primer FP2. Perform PCR using the following cycles:

Initial step:	2 min	94°C
31 cycles:	45 sec	94°C
	45 sec	56°C
	45 sec	72°C.

   These conditions have been used successfully to amplify fragments up to 1.8 kb in length; some modifications, such as extension of elongation time, are also effective.

6. Load 20 µl of the PCR reaction product on a 0.7% low melting temperature agarose gel (*APPENDIX 4F*) to resolve PCR products. Based on insert sizes, group the obtained interactors in families, i.e., potential multiple independent isolates of identical cDNAs. Reserve gel until results of step 7 are obtained.

   No special precautions are needed for storing the gel. Since HaeIII digests typically yield rather small DNA fragments, running the second gel does not take a lot of time. Usually, the delay does not exceed 45 to 60 min, during which time the first gel may be stored in a gel box at room temperature or wrapped in plastic wrap at 4°C.

7. While the gel is running, use the remaining 10 µl of PCR reaction product for a restriction endonuclease digestion with *Hae*III in a digestion volume of ~20 µl (*APPENDIX 4I*). Based on analysis of the sizes of undigested PCR products in the gel (step 6), rearrange the tubes with *Hae*III digest samples so that those thought to represent a family are side by side. Resolve the digests on a 2% to 2.5% agarose gel (*APPENDIX 4F*).

   Most restriction fragments will be in the 200-bp to 1.0-kb size range so using a long gel run is advisable. This analysis should produce a distinct fingerprint of insert sizes and allow definition of library cDNAs as unique isolates or related groups.

   A single positive yeast will sometimes contain multiple library plasmids. An advantage of this protocol is the ready detection of multiple library plasmids in PCR reactions; thus, following subsequent bacterial transformations, only a single TRP1 colony would need to be analyzed unless multiple plasmids were already known to be present.

8. Isolate DNA fragments from the low melting temperature agarose gel (step 6).

   If inspection of the banding pattern on the two gels suggests that a great many reisolates of a small number of cDNAs are present, it may be worthwhile to immediately sequence PCR products representative of these clusters, but it is generally still advisable to continue through specificity tests before doing so. If the PCR products are sequenced, the FP1 forward primer works well in automated sequencing of PCR fragments, but the FP2 primer is only effective in sequencing from purified plasmid.

   In general, priming from the AT-rich ADH terminator downstream of the polylinker/cDNA in library plasmid is less efficient than from upstream of the cDNA, and it is hard to design effective primers in this region.

BRIJ IAS / CENTRAL UNIVERSITY LIBRARY

9. Remove the microtiter plate of lysates from the freezer, thaw it, and remove 2 to 4 μl of lysed yeast for each desired positive. Electroporate DNA into either DH5α or KC8 *E. coli* as appropriate, depending on the choice of bait and reporter plasmids (see Table 19.2.1 and see Background Information for further information). Refreeze the plate as a DNA reserve in case bacteria fail to transform on the first pass.

   KC8 E. coli should be used for electroporation when the original reagents pEG202/pJG4-5/pJK101 are used for the interaction trap.

   An additional strength of this protocol is that it identifies redundant clones before transfer of plasmids to bacteria, thus reducing the amount of work required in cases where plasmid identity can be unambiguously assigned. However, although restriction endonuclease digestion and PCR analysis are generally highly predictive, they are not 100% certain methods for estimating cDNA identity. Thus, if there is any doubt about whether two cDNAs are the same, investigators are urged to err on the side of caution.

10. Prepare a miniprep of plasmid DNA from the transformed bacteria (*APPENDIX 4C*) and perform yeast transformation and specificity assessment (see Basic Protocol 2, steps 24 to 28).

PERFORMING A HUNT BY INTERACTION MATING

ALTERNATE PROTOCOL 2

An alternative way of conducting an interactor hunt is to mate a strain that expresses the bait protein with a strain that has been pretransformed with the library DNA, and screen the resulting diploid cells for interactors (Bendixen et al., 1994; Finley and Brent, 1994). This "interaction mating" approach can be used for any interactor hunt, and is particularly useful in three special cases. The first case is when more than one bait will be used to screen a single library. Interaction mating allows several interactor hunts with different baits to be conducted using a single high-efficiency yeast transformation with library DNA. This can be a considerable savings, since the library transformation is one of the most challenging tasks in an interactor hunt. The second case is when a constitutively expressed bait interferes with yeast viability. For such baits, performing a hunt by interaction mating avoids the difficulty associated with achieving a high-efficiency library transformation of a strain expressing a toxic bait. Moreover, the actual selection for interactors will be conducted in diploid yeast, which are more vigorous than haploid yeast and can better tolerate expression of toxic proteins. The third case is when a bait cannot be used in a traditional interactor hunt using haploid yeast strains (see Basic Protocol 2) because it activates transcription of even the least sensitive reporters. In diploids the reporters are less sensitive to transcription activation than they are in haploids. Thus, the interaction mating hunt provides an additional method to reduce background from transactivating baits.

In the protocol described below, the library DNA is used to transform a strain with a *LEU2* reporter (e.g., EGY48). This pretransformed library strain is then frozen in many aliquots, which can be thawed and used for individual interactor hunts. The bait is expressed in a strain of mating type opposite to that of the pretransformed library strain, and also bearing the *lacZ* reporter. A hunt is conducted by mixing the pretransformed library strain with the bait strain and allowing diploids to form on YPD medium overnight. The diploids are then induced for expression of the library-encoded proteins and screened for interactors as in Basic Protocol 2.

NOTE: Strain combinations other than those described below can also be used in an interaction-mating hunt. The key to choosing the strains is to ensure that the bait and prey strains are of opposite mating types and that both have auxotrophies to allow selection for the appropriate plasmids and reporter genes. Also, once the bait plasmid and *lacZ* reporter plasmid have been introduced into the bait strain, and the library plasmids have

BAYLOR COLLEGE OF MEDICINE LIBRARY

been introduced into the library strain, the resulting bait strain and library strain must each have auxotrophies that can be complemented by the other, so that diploids can be selected.

Additional Materials (also see Basic Protocols 1 and 2)

Yeast strains: either RFY206 (Finley and Brent, 1994), YPH499 (Sikorski and Hieter, 1989; ATCC #6625), or an equivalent *MATa* strain with auxotrophic markers *ura3*, *trp1*, *his3*, and *leu2*
YPD liquid medium (*APPENDIX 4L*)
Glu/CM –Trp plates: CM dropout plates –Trp (*APPENDIX 4L*) supplemented with 2% glucose
pJG4-5 library vector (Fig. 19.2.6), empty
100-mm YPD plates (*APPENDIX 4L*)

Additional reagents and equipment for lithium acetate transformation of yeast (*APPENDIX 4L*)

Construct the bait strain

The bait strain will be a *MATa* yeast strain (mating type opposite of EGY48) containing a *lacZ* reporter plasmid like pSH18-34 and the bait-expressing plasmid, pBait.

1. Perform construction of the bait plasmid (pBait; see Basic Protocol 1, step 1).

2. Cotransform the *MATa* yeast strain (e.g., either RFY206 or YPH499) with pBait and pSH18-34 using the lithium acetate method (*APPENDIX 4L*). Select transformants on Glu/CM –Ura,–His plates by incubating plates at 30°C for 3 to 4 days until colonies form. Combine 3 colonies for all future tests and for the mating hunt.

   The bait strain (RFY206/pSH18-34/pBait or YPH499/pSH18-34/pBait) can be tested by immunoblotting to ensure that the bait protein is expressed (see Support Protocol 1). Synthesis and nuclear localization of the bait protein can also be tested by the repression assay (see Basic Protocol 1, steps 8 to 12).

3. *Optional:* Assay *lacZ* gene activation in the bait strain (see Basic Protocol 1, steps 4 to 7).

   If the bait activates the lacZ reporter, a less sensitive lacZ reporter plasmid (Table 19.2.1), or an integrated version of the lacZ reporter should be tried. A bait that strongly activates the lacZ reporters usually cannot be used in a hunt based on selection of interactors with the LEU2 reporter, because the LEU2 reporters are more sensitive than the lacZ reporters. However, both reporters are less sensitive to activation by a bait in diploid cells, as compared to haploid cells. Thus, a more important test of the transactivation potential of a bait is to test the leucine requirement of diploid cells expressing it, as described in steps 6 to 20, below.

Prepare the pretransformed library strain (EGY48 + library plasmids)

4. Perform a large-scale transformation of EGY48 with library DNA using the lithium acetate method (see Basic Protocol 2, steps 1 to 8, except start with EGY48 bearing no other plasmids). To prepare for transformation, grow EGY48 in YPD liquid medium. Select library transformants on Glu/CM –Trp plates by incubating 3 days at 30°C.

5. Collect primary transformants by scraping plates, washing yeast, and resuspending in 1 pellet vol glycerol solution (see Basic Protocol 2, steps 9 to 12). Freeze 0.2 to 1.0 ml aliquots at –70° to –80°C.

   The cells will be stable for at least 1 year. Refreezing a thawed aliquot will result in loss of viability. Thus, many frozen aliquots should be made, so that each thawed aliquot can be discarded after use.

BJU IASI CENTRAL UNIVERSITY LIBRARY

Prepare the pretransformed control strain (EGY48 + pJG4-5)

6. Transform EGY48 grown in YPD liquid medium with the empty library vector, pJG4-5, using the lithium acetate method (*APPENDIX 4L*). Select transformants on Glu/CM –Trp plates by incubating 3 days at 30°C.

7. Pick and combine three transformant colonies and use them to inoculate 30 ml of Glu/CM –Trp medium. Incubate 15 to 24 hr at 30°C (to OD_{600} >3).

8. Centrifuge 5 min at 1000 to 1500 × *g*, room temperature, and remove supernatant. Resuspend in 10 ml sterile water to wash cells.

9. Centrifuge 5 min at 1000 to 1500 × *g*, room temperature, and remove supernatant. Resuspend in 1 pellet vol glycerol solution and freeze 100-µl aliquots at –70° to –80°C.

Determine plating efficiency of pretransformed library and pretransformed control strains

10. After freezing (at least 1 hr) thaw an aliquot of each pretransformed strain (from step 5 and step 9) at room temperature. Make several serial dilutions in sterile water, including aliquots diluted 10^5-fold, 10^6-fold, and 10^7-fold. Plate 100 µl of each dilution on 100-mm Glu/CM –Trp plates and incubate 2 to 3 days at 30°C.

11. Count the colonies and determine the number of colony-forming units (cfu) per aliquot of transformed yeast.

    The plating efficiency for a typical library transformation and for the control strain will be ~1 × 10^8 cfu per 100 µl.

Mate the bait strain with the pretransformed library strain and the pretransformed control strain

In steps 12 through 20, an interactor hunt is conducted concurrently with testing *LEU2* reporter activation by the bait itself. For most baits, this approach will be the quickest way to isolate interactors. However, for some baits, such as those that have a high transactivation potential, or those that affect yeast mating or growth, steps 12 through 20 will serve as a pilot experiment to determine the optimal parameters for a subsequent hunt.

12. Grow a 30-ml culture of the bait strain in Glu/CM –Ura,–His liquid dropout medium to mid to late log phase (OD_{600} = 1.0 to 2.0, or 2 to 4 × 10^7cells/ml).

    A convenient way to grow the bait strain is to inoculate a 5-ml culture with approximately three colonies from a plate and grow it overnight at 30°C with shaking. In the morning, measure the OD_{600}, dilute into a 30-ml culture to a final OD_{600} = 0.2, and grow at 30°C with shaking. The culture should reach mid to late log phase before the end of the day.

13. Centrifuge the culture 5 min at 1000 to 1500 × *g*, room temperature, to harvest cells. Resuspend the cell pellet in sterile water to make a final volume of 1 ml.

    This should correspond to ~1 × 10^9 cells/ml.

14. Set up two matings. In one sterile microcentrifuge tube mix 200 µl of the bait strain with 200 µl of a thawed aliquot of the pretransformed control strain from step 9. In a second microcentrifuge tube mix 200 µl of the bait strain with ~1 × 10^8 cfu (~0.1 to 1 ml) of the pretransformed library strain from step 5.

    The library mating should be set up so that it contains a ~2-fold excess of bait strain cfu over pretransformed library strain cfu. Because the bait strain was harvested in log phase, most of the cells will be viable (i.e., cells/ml = ~cfu/ml), and the number of cfu can be sufficiently estimated from optical density (1 OD_{600} = ~2 × 10^7 cells/ml). Under these conditions, ~10% of the cfu in the pretransformed library strain will mate with the bait

BCU LRSI/OETRAD UNIVERSITY LIBRARY

strain. Thus, a complete screen of 10^7 library transformants will require a single mating with at least 10^8 cfu of the pretransformed library strain and at least 2×10^8 cfu of the bait strain.

To screen more library transformants, set up additional matings. The number of pretransformed library transformants to screen depends on the size of the library and the number of primary transformants obtained in step 5. If the size of the library is larger than the number of transformants obtained in step 5, the goal will be to screen all of the yeast transformants. In this case, complete screening of the library will require additional transformations of EGY48 and additional interactor hunts. If the size of the library is smaller than the number of transformants obtained in step 5, the goal will be to screen at least a number of transformants equivalent to the size of the library.

15. Centrifuge each cell mixture for 5 min at 1000 to 1500 × *g*, pour off medium, and resuspend cells in 200 µl YPD medium. Plate each suspension on a 100-mm YPD plate. Incubate 12 to 15 hr at 30°C.

16. Add ~1 ml of Gal/Raff/CM –Ura, –His, –Trp to the lawns of mated yeast on each plate. Mix the cells into the medium using a sterile applicator stick.

17. Transfer each slurry of mated cells to a 500-ml flask containing 100 ml of Gal/Raff/CM –Ura, –His, –Trp dropout medium. Incubate with shaking 6 hr at room temperature to induce the *GAL1* promoter, which drives expression of the cDNA library.

18. Centrifuge the cell suspensions 5 min at 1000 to 1500 × *g*, room temperature, to harvest the cells. Wash by resuspending in 30 ml of sterile water and centrifuging again. Resuspend each pellet in 5 ml sterile water. Measure OD_{600} and, if necessary, dilute to a final concentration of $\sim 1 \times 10^8$ cells/ml.

This is a mixture consisting of haploid cells that have not mated and diploid cells. Under a microscope, the two cell types can be distinguished by size (diploids are ~1.7× bigger than haploids) and shape (diploids are slightly oblong and haploids are spherical). Because diploids grow faster than haploids, this mixture will contain ~10% to 50% diploid cells. The actual number of diploids will be determined by plating dilutions on –Ura, –His, –Trp medium, which will not support the growth of the parental haploids.

19. For each mating make a series of $1/10$ dilutions in sterile water, at least 200 µl each, to cover a 10^6-fold concentration range. Plate 100 µl from each tube (undiluted, 10^{-1}, 10^{-2}, 10^{-3}, 10^{-4}, 10^{-5}, and 10^{-6} dilution) on 100-mm Gal/Raff/CM –Ura, –His, –Trp, –Leu plates. Plate 100 µl from the 10^{-4}, 10^{-5}, and 10^{-6} tubes on 100-mm Gal/Raff/CM –Ura, –His, –Trp plates. Incubate plates at 30°C. Count the colonies on each plate after 2 to 5 days.

20. For the mating with the pretransformed library, prepare an additional 3 ml of a 10^{-1} dilution. Plate 100 µl of the 10^{-1} dilution on each of 20 100-mm Gal/Raff/CM –Ura, –His, –Trp, –Leu plates. Also plate 100 µl of the undiluted cells on each of 20 100-mm Gal/Raff/CM –Ura, –His, –Trp, –Leu plates. Incubate at 30°C. Pick Leu^+ colonies after 2 to 5 days and characterize them beginning with step 17 of Basic Protocol 2.

The number of Leu^+ colonies to pick to ensure that all of the pretransformed library has been screened depends on the transactivation potential of the bait protein itself. The transactivation potential is expressed as the number of Leu^+ colonies that grow per cfu (Leu^+/cfu) of the bait strain mated with the control strain, as determined in step 19 of this protocol. It can be calculated as the ratio of the number of colonies that grow on Gal/Raff/CM –Ura,–His, –Trp, –Leu to the number of colonies that grow on Gal/Raff/CM –Ura, –His, –Trp for a given dilution of the mating between the bait strain and the control strain. A bait with essentially no transactivation potential will produce less than 10^{-6} Leu^+/cfu. For a bait to be useful in an interactor hunt it should not transactivate more than 10^{-4} Leu^+/cfu.

BIU IASI CENTRAL UNIVERSITY LIBRARY

To screen all of the pretransformed library, it will be necessary to pick a sufficient number of Leu$^+$ colonies in addition to background colonies produced by the transactivation potential of the bait itself. Thus, the minimum number of Leu$^+$ colonies that should be picked in step 20 of this protocol is given by:

(transactivation potential, Leu$^+$/cfu) × (# library transformants screened).

For example, if 10^7 library transformants were obtained in step 2 (and at least 10^8 cfu of these transformants were mated with the bait strain in step 14, since only ~10% will form diploids), and the transactivation potential of the bait is 10^{-4} Leu$^+$/cfu, then at least 1000 Leu$^+$ colonies must be picked and characterized. In other words, if the rarest interactor is present in the pretransformed library at a frequency of 10^{-7}, to find it one needs to screen through at least 10^7 diploids from a mating of the library strain. However, at least 1000 of these 10^7 diploids would be expected to be Leu$^+$ due to the bait background if the transactivation potential of the bait is 10^{-4}. The true positives will be distinguished from the bait background in the next step by the galactose dependence of their Leu$^+$ and lacZ$^+$ phenotypes.

PREPARATION OF PROTEIN EXTRACTS FOR IMMUNOBLOT ANALYSIS

SUPPORT PROTOCOL 1

To confirm that the bait fusion protein constructed in Basic Protocol 1 is synthesized properly, a crude lysate is prepared for SDS-PAGE and immunoblot analysis (*UNITS 10.1 & 10.10*). The presence of the target protein is detected by antibody to LexA or the fusion domain.

Materials

Master plates with pBait-containing positive and control yeast on Glu/CM –Ura, –His dropout medium (see Basic Protocol 1, step 4)

Glu/CM –Ura, –His dropout liquid medium: CM dropout plates –Ura, –His (*APPENDIX 4L*) supplemented with 2% glucose

2× Laemmli sample buffer (see recipe)

Antibody to fusion domain or LexA: monoclonal antibody to LexA (Clontech, Invitrogen) or polyclonal antibody to LexA (available by request from R. Brent or E. Golemis)

30°C incubator

100°C water bath

Additional reagents and equipment for SDS-PAGE (*UNIT 10.1*) and immunoblotting and immunodetection (*UNIT 10.10*)

1. From the master plates, start a 5-ml culture in Glu/CM –Ura, –His liquid medium for each bait being tested and for a positive control for protein expression (i.e., RFHMI or SH17-4). Incubate overnight at 30°C.

   For each construct assayed, it is a good idea to grow colonies from at least two primary transformants, as levels of bait expression are sometimes heterogenous.

2. From each overnight culture, start a fresh 5-ml culture in Glu/CM –Ura, –His at OD_{600} = ~0.15. Incubate again at 30°C.

3. When the culture has reached OD_{600} = 0.45 to 0.7 (~4 to 6 hr), remove 1.5 ml to a microcentrifuge tube.

   For some LexA fusion proteins, levels of the protein drop off rapidly in cultures approaching stationary phase. This is due to a combination of the diminishing activity of the ADH1 promoter in late growth phases and the relative instability of particular fusion domains. Thus, it is not a good idea to let cultures become saturated in the hopes of obtaining a higher yield of protein.

BCUVAS/CENTRAL UNIVERSITY LIBRARY

4. Microcentrifuge cells 3 min at 13,000 × *g*, room temperature. When the pellet is visible, remove the supernatant.

   Inspection of the tube should reveal a pellet ~1 to 3 µl in volume. If the pellet is not visible, microcentrifuge another 3 min.

5. Working rapidly, add 50 µl of 2× Laemmli sample buffer to the visible pellet in the tube, vortex, and place the tube on dry ice.

   Samples may be frozen at –70°C.

6. Transfer frozen sample directly to a boiling water bath or a PCR machine set to cycle at 100°C. Boil 5 min.

7. Microcentrifuge 5 sec at maximum speed to pellet large cellular debris.

8. Perform SDS-PAGE (*UNIT 10.1*) using 20 to 50 µl sample per lane.

9. To detect the protein, immunoblot and analyze (*UNIT 10.10*) using antibody to the fusion domain or LexA.

SUPPORT PROTOCOL 2

PREPARATION OF SHEARED SALMON SPERM CARRIER DNA

This protocol generates high-quality sheared salmon sperm DNA (sssDNA) for use as carrier in transformation (Basic Protocol 2). This DNA is also suitable for other applications where high-quality carrier DNA is needed (e.g., hybridization). This protocol is based on Schiestl and Gietz (1989). For more details of phenol extraction or other DNA purification methods, consult *APPENDIX 4E*.

Materials

High-quality salmon sperm DNA (e.g., sodium salt from salmon testes, Sigma or Boehringer Mannheim), desiccated
TE buffer, pH 7.5 (*APPENDIX 2E*), sterile
TE-saturated buffered phenol (*APPENDIX 2E*)
1:1 (v/v) buffered phenol/chloroform
Chloroform
3 M sodium acetate, pH 5.2 (*APPENDIX 2E*)
100% and 70% ethanol, ice cold

Magnetic stirring apparatus and stir-bar, 4°C
Sonicator with probe
50-ml conical centrifuge tube
High-speed centrifuge and appropriate tube
100°C and ice-water baths

1. Dissolve desiccated high-quality salmon sperm DNA in TE buffer, pH 7.5, at a concentration of 5 to 10 mg/ml by pipetting up and down in a 10-ml glass pipet. Place in a beaker with a stir-bar and stir overnight at 4°C to obtain a homogenous viscous solution.

   It is important to use high-quality salmon sperm DNA. Sigma Type III sodium salt from salmon testes has worked well, as has a comparable grade from Boehringer Mannheim. Generally it is convenient to prepare 20- to 40-ml batches at a time.

2. Shear the DNA by sonicating briefly using a large probe inserted into the beaker.

   The goal of this step is to generate sheared salmon sperm DNA (sssDNA) with an average size of 7 kb, but ranging from 2 to 15 kb. Oversonication (such that the average size is closer to 2 kb) drastically decreases the efficacy of carrier in enhancing transformation. The original version of this protocol (Schiestl and Gietz, 1989) called for two 30-sec pulses at

BJU IASI CENTRAL UNIVERSITY LIBRARY

Table 19.2.4 Two-hybrid System Variants[a]

System	DNA-binding domain	Activation domain	Selection	Reference
Two-hybrid	*GAL4*	*GAL4*	Activation of *lacZ*, *HIS3*	Chien et al., 1991
Interaction trap	*LexA*	*B42*	Activation of *LEU2*, *lacZ*	Gyuris et al., 1993
"Improved two-hybrid"	*GAL4*	*GAL4*	Activation of *HIS3*, *lacZ*	Durfee at al., 1993
Modified two-hybrid	*LexA*	VP16	Activation of *HIS3*, *lacZ*	Vojtek at al., 1993
KISS	*GAL4*	VP16	Activation of *CAT*, *hyg*^{r}	Fearon et al., 1992
Contingent replication	*GAL4*	VP16	Activation of T-Ag, replication of plasmids	Vasavada et al., 1991

[a]Abbreviations: *CAT*, chloramphenicol transferase gene; *hyg*^{r}, hygromycin resistance gene; T-Ag, viral large T antigen.

three-quarter power, but optimal conditions vary between sonicators. The first time this protocol is performed, it is worthwhile to sonicate briefly, then test the size of the DNA by running out a small aliquot alongside molecular weight markers on an agarose gel containing ethidium bromide. The DNA can be sonicated further if needed.

3. Once DNA of the appropriate size range has been obtained, extract the sssDNA solution with an equal volume of TE-saturated buffered phenol in a 50-ml conical tube, shaking vigorously to mix.
4. Centrifuge 5 to 10 min at 3000 × *g*, room temperature, or until clear separation of phases is obtained. Transfer the upper phase containing the DNA to a clean tube.
5. Repeat extraction using 1:1 (v/v) buffered phenol/chloroform, then chloroform alone. Transfer the DNA into a tube suitable for high-speed centrifugation.
6. Precipitate the DNA by adding 1/10 vol of 3 M sodium acetate and 2.5 vol of ice-cold 100% ethanol. Mix by inversion. Centrifuge 15 min at ~12,000 × *g*, room temperature.
7. Wash the pellet with 70% ethanol. Briefly dry either by air drying, or by covering one end of the tube with Parafilm with a few holes poked in and placing the tube under vacuum. Resuspend the DNA in sterile TE buffer at 5 to 10 mg/ml.

   Do not overdry the pellet or it will be very difficult to resuspend.
8. Denature the DNA by boiling 20 min in a 100°C water bath. Then immediately transfer the tube to an ice-water bath.
9. Place aliquots of the DNA in microcentrifuge tubes and store frozen at –20°C. Thaw as needed.

   DNA should be boiled again briefly (5 min) immediately before addition to transformations.

   Before using a new batch of sssDNA in a large-scale library transformation, it is a good idea to perform a small-scale transformation using suitable plasmids to determine the transformation efficiency. Optimally, use of sssDNA prepared in the manner described will yield transformation frequencies of >10^5 colonies/μg input plasmid DNA.

BCU IASI CENTRAL UNIVERSITY LIBRARY

YEAST COLONY HYBRIDIZATION

This protocol is adapted from a modification of the classic protocol of Grunstein and Hogness (1975; Kaiser et al., 1994). It is primarily useful when a large number of putative interactors has been obtained, and initial minipreps and restriction digests have indicated that many of them derive from a small number of cDNAs; these cDNAs can then be used as probes to screen and eliminate identical cDNAs from the pool.

Materials

Glu/CM –Trp plates: CM dropout plates –Trp (*APPENDIX 4L*) supplemental with 2% glucose
Master dropout plate of yeast positive for Gal dependence (see Basic Protocol 2, step 18)
1 M sorbitol/20 mM EDTA/50 mM DTT (prepare fresh)
1 M sorbitol/20 mM EDTA
0.5 M NaOH
0.5 M Tris·Cl (pH 7.5)/6× SSC (*APPENDIX 2E*)
2× SSC (*APPENDIX 2E*)
100,000 U/ml β-glucuronidase (type HP-2 crude solution from *Helix pomatia*; Sigma)

82-mm circular nylon membrane, sterile
Whatman 3MM paper
80°C vacuum oven *or* UV cross-linker

Additional reagents and equipment for bacterial filter hybridization (Strauss, 1993; Duby et al., 1988)

1. Place a sterile nylon membrane onto a Glu/CM –Trp dropout plate. From the master dropout plate of Gal-dependent positives, gently restreak positives to be screened onto the membrane and mark the membrane to facilitate future identification of hybridizing colonies. Grow overnight (~12 hr) at 30°C.

   Growth for extended periods of time (i.e., 24 hr) may result in difficulty in obtaining good lysis. It is a good idea to streak positive and negative controls for the cDNAs to be hybridized on the membrane.

2. Remove membrane from plate. Air dry briefly. Incubate ~30 min on a sheet of Whatman 3MM paper saturated with 1 M sorbitol/20 mM EDTA/50 mM DTT.

   Optionally, before commencing chemical lysis, membranes can be placed at –70°C for 5 min, then thawed at room temperature for one or more cycles to enhance cell wall breakage.

3. Cut a piece of Whatman 3MM paper to fit inside a 100-mm petri dish. Place the paper disc in the dish and saturate with 100,000 U/ml β-glucuronidase diluted 1:500 in 1 M sorbitol/20 mM EDTA (2 µl glucuronidase per ml of sorbitol/EDTA to give 200 U/ml final). Layer nylon membrane on dish, cover dish, and incubate up to 6 hr at 37°C until >80% of the cells lack a cell wall.

   The extent of cell wall removal can be determined by removing a small quantity of cells from the filter to a drop of 1 M sorbitol/20 mM EDTA on a microscope slide and observing directly with a phase-contrast microscope at ≥60× magnification. Cells lacking cell wall are nonrefractile.

4. Place membrane on Whatman 3MM paper saturated with 0.5 M NaOH for ~8 to 10 min.

5. Place membrane on Whatman 3MM paper saturated with 0.5 M Tris·Cl (pH 7.5)/6× SSC for 5 min. Repeat with a second sheet of Whatman 3MM paper.

BAU IASI CENTRAL UNIVERSITY LIBRARY

6. Place membrane on Whatman 3MM paper saturated with 2× SSC for 5 min. Then place membrane on dry Whatman paper to air dry for 10 min.
7. Bake membrane 90 min at 80°C in vacuum oven or UV cross-link.
8. Process as for bacterial filter hybridization (Strauss, 1993; Duby et al., 1988), hybridizing the membrane with probes complementary to previously isolated cDNAs.

When selecting probes, either random-primed cDNAs or oligonucleotides complementary to the cDNA sequence may be used. If the cDNA is a member of a protein family, it may be advantageous to use oligonucleotides to avoid inadvertently excluding genes related but not identical to those initially obtained.

MICROPLATE PLASMID RESCUE

SUPPORT PROTOCOL 4

In some cases, it is desirable to isolate plasmids from a large number of positive colonies (Basic Protocol 2, steps 18 and 19). The protocol described below is a batch DNA preparation protocol developed by Steve Kron (University of Chicago, Chicago, Ill.) as a scale-up of a basic method developed by Manuel Claros (Laboratoire de Génétique Moleculaire, Paris, France).

Materials

2× Glu/CM –Trp liquid medium: 2× CM –Trp liquid medium (*APPENDIX 4L*) supplemented with 4% glucose
Master plate of Gal-dependent yeast colonies (see Basic Protocol 2, step 18)
Rescue buffer: 50 mM Tris·Cl (pH 7.5)/10 mM EDTA/0.3% (v/v) 2-mercaptoethanol (prepare fresh)
Lysis solution: 2 to 5 mg/ml Zymolyase 100T/rescue buffer *or* 100,000 U/ml β-glucuronidase (type HP-2 crude solution from *Helix pomatia*; Sigma) diluted 1:50 in rescue buffer
10% (w/v) SDS
7.5 M ammonium acetate
Isopropanol
70% ethanol
TE buffer, pH 8.0 (*APPENDIX 2E*)

24-well microtiter plates
Centrifuge with microplate holders, refrigerated
Repeating micropipettor
37°C rotary shaker

Grow yeast cultures

1. Aliquot 2 ml of 2× Glu/CM –Trp medium into each well of a 24-well microtiter plate. Into each well, pick a putative positive colony. Grow overnight with shaking at 30°C.

The 2× minimal medium is used to maximize the yield of yeast. Four plates can generally be handled conveniently at once, based on the number that can be centrifuged simultaneously.

2. Centrifuge 5 min at 1500 × *g*, 4°C. Shake off supernatant with a snap and return the plate to upright.
3. Swirl or lightly vortex the plate to resuspend cell pellets in remaining liquid. Add 1 ml water to each well and swirl lightly.

Cell pellets can most easily be resuspended in residual liquid before adding new solutions. Addition of liquid can be accomplished using a repeating pipettor.

BCU LASS / CENTRAL UNIVERSITY LIBRARY

4. Centrifuge 5 min at 1500 × *g*, 4°C. Shake off supernatant and resuspend pellet. Add 1 ml rescue buffer.
5. Centrifuge 5 min at 1500 × *g*, 4°C. Shake off supernatant and resuspend pellet in the small volume of liquid remaining in the plate.

Lyse cells

6. To each well, add 25 µl lysis solution. Swirl or vortex to mix. Incubate (with cover on) on a rotary shaker ~1 hr at 37°C.

   Lysis solution need not be completely dissolved before use. By 1 hr, lysis should be obvious as coagulation of yeast into a white precipitate.

   Susceptibility of yeast strains to lytic enzymes varies. If lysis occurs rapidly, then less lytic enzyme should be used. If the lysis step is allowed to go too far, too much of the partially dissolved cell wall may contaminate the final material. Lysis can be judged by examining cells with a phase-contrast microscope. Living cells are white with a dark halo and dead cells are uniformly gray. Lysis leads to release of granular cell contents into the medium. Once cells are mostly gray and many are disrupted, much of the plasmid should have been released.

7. To each well, add 25 µl of 10% SDS. Mix gently by swirling to completely disperse the precipitates. Allow plates to sit 1 min at room temperature.

   At this point, the wells should contain a clear, somewhat viscous solution.

Purify plasmid

8. To each well, add 100 µl of 7.5 M ammonium acetate. Swirl gently, then incubate 15 min at –70°C or –20°C until frozen.

   Addition of acetate should result in the formation of a massive white precipitate of cell debris and SDS. The freezing step appears to improve removal of inhibitors of E. coli transformation.

9. Remove plate from freezer. Once it begins to thaw, centrifuge 15 min at 3000 × *g*, 4°C. Transfer 100 to 150 µl of the resulting clear supernatants to clean 24-well plates.

   In general, some contamination of the supernatant with pelleted material cannot be avoided. However, it is better to sacrifice yield in order to maintain purity.

10. To each well, add ~0.7 vol isopropanol. Mix by swirling and allow to precipitate 2 min at room temperature.

    A cloudy fine precipitate should form immediately after isopropanol is added.

11. Centrifuge 15 min at 3000 × *g*, 4°C. Shake off supernatant with a snap.
12. To each well, add ~1 ml cold 70% ethanol. Mix by swirling, centrifuge 5 min at 3000 × *g*, 4°C. Shake off supernatant with a snap, invert plates and blot well onto paper towel. Allow plates to air dry.
13. To each well, add 100 µl TE buffer. Swirl well and allow to rest on bench several minutes, until the pellets appear fully dissolved. Transfer preps to microcentrifuge tubes or 96-well plates for storage at –20°C.

    One to five microliters of each of the resulting preparations can be used to transform competent E. coli: for KC8, electroporation should be used (see Basic Protocol 2, step 21). Sometimes, the yield of transformants is low if E. coli carrying plasmids are not permitted time to increase the plasmid copy number above a critical threshold before the cells are placed on selective medium. Allow plenty of time for cells to express antibiotic resistance or the TRP1 gene before plating.

    If insufficient numbers of colonies are obtained by this approach, the final plasmid preparation can be resuspended in 20 µl instead of 100 µl TE buffer to concentrate the DNA stock.

BJU IASL CENTRAL UNIVERSITY LIBRARY

ADDITIONAL SPECIFICITY SCREENING

The three test plasmids outlined (pSH18-34, pRFHM1, and pEG202; see Basic Protocol 2, step 24) represent a minimal test series. If other LexA-bait proteins that are related to the bait protein used in the initial library screen are available, substantial amounts of information can be gathered by additional specificity tests. For example, if the initial bait protein was LexA fused to the leucine zipper of c-Fos, specificity screening of interactor-hunt positives against the leucine zippers of c-Jun or GCN4 in addition to that of c-Fos might allow discrimination between proteins that are specific for fos versus those that generically associate with leucine zippers.

REAGENTS AND SOLUTIONS

Use deionized, distilled water in all recipes and protocol steps. For common stock solutions, see APPENDIX 2; for suppliers, see APPENDIX 4.

Glycerol solution

65% (v/v) glycerol, sterile
0.1 M $MgSO_4$
25 mM Tris·Cl, pH 8.0 (*APPENDIX 2E*)
Store up to 1 year at room temperature

Laemmli sample buffer, 2×

10% (v/v) 2-mercaptoethanol (2-ME)
6% (w/v) SDS
20% (v/v) glycerol
0.2 mg/ml bromphenol blue
0.025× Laemmli stacking buffer (see recipe; optional)
Store up to 2 months at room temperature

This reagent can conveniently be prepared 10 ml at a time.

Laemmli stacking buffer, 2.5×

0.3 M Tris·Cl, pH 6.8
0.25% (w/v) SDS
Store up to 1 month at 4°C

Lysis solution

50 mM Tris·Cl, pH 7.5 (*APPENDIX 2E*)
10 mM EDTA
0.3% (v/v) 2-mercaptoethanol (2-ME), added just before use
2% (v/v) β-glucuronidase from *Helix pomatia* (Type HP-2; Sigma), added just before use

COMMENTARY

Background Information

Interaction-based cloning is derived from three experimental observations. In the first, Brent and Ptashne (1985) demonstrated that it was possible to assemble a novel, functional transcriptional activator by fusing the DNA-binding domain from one protein, LexA, to the activation domain from a second protein, GAL4. This allowed the use of a single reporter system containing a single DNA-binding motif, the *LexA* operator, to study transcriptional activation by any protein of interest. In the second, Ma and Ptashne (1988) built on this work to demonstrate that the activation domain could be brought to DNA by interaction with a DNA-binding domain. In the third, Fields and Song (1989), working independently of Ma and Ptashne, used two yeast proteins, SNF1 and SNF4, to make an SNF1 fusion to the DNA-binding domain of GAL4 and an SNF4 fusion to the GAL4 activation domain. They demonstrated that the strength of the SNF1-SNF4

BOSTON / CENTRAL UNIVERSITY LIBRARY

interaction was sufficient to allow activation through a GAL4 DNA-binding site. From this, they suggested the feasibility of selecting interacting proteins by performing screens of cDNA libraries made so that library-encoded proteins carried activating domains.

Several groups have developed cDNA library strategies along these lines, with some systems using LexA and others using GAL4 as the DNA-binding domain (Table 19.2.4). LexA and GAL4 each have different properties that should be considered when selecting a system. LexA is derived from a heterologous organism, has no known effect on the growth of yeast, possesses no residual transcriptional activity, can be used in GAL4$^+$ yeast, and can be used with a Gal-inducible promoter. Because GAL4 is an important yeast transcriptional activator, it has the disadvantage that experiments must be performed in gal4$^-$ yeast strains to avoid background due to activation of the reporter system by endogenous GAL4. Such gal4$^-$ strains are frequently less healthy and more difficult to transform than wild-type strains, and either libraries must be constitutively expressed or alternate inducible systems must be used. By contrast, the GAL4 DNA-binding domain may be more efficiently localized to the nucleus and may be preferred for some proteins (for a review of GAL4-based systems, see Bartel et al., 1993). Whichever system is used, it is important to remember that the bait protein constitutes a novel fusion protein whose properties may not exactly parallel those of the original unfused protein of interest. Although systems using the two-hybrid paradigm have been developed in mammalian cells (see Table 19.2.4), these have not been used effectively in library screens. It seems likely that the organism of choice for two-hybrid identification of novel partner proteins will remain yeast.

cDNAs that pass specificity tests are referred to as positives, or "true positives." In interactor hunts conducted to date, anywhere from zero to practically all isolated plasmids passed the final specificity test. If no positives are obtained, the tissue source for the library originally used may not be appropriate, and a different library may produce better results. However, there are some proteins for which no positives are found. Various explanations for this are provided below. Conversely, some library-encoded proteins are known to be isolated repeatedly using a series of unrelated baits, and these proteins demonstrate at least some specificity. One of these, heat shock protein 70, might be explained by positing that it assists the folding of some LexA-fused bait proteins, or alternatively, that these bait proteins are not normally folded. This example illustrates the point that the physiological relevance of even quite specific interactions may sometimes be obscure.

Because the screen involves plating multiple cells to Gal/CM –Ura, –His, –Trp, –Leu dropout medium for each primary transformant obtained, multiple reisolates of true positive cDNAs are frequently obtained. If a large number of specific positives are obtained, it is generally a good idea to attempt to sort them into classes—for example, digesting minipreps of positives with *Eco*RI, *Xho*I, and *Hae*III will generate a fingerprint of sufficient resolution to determine whether multiple reisolates of a small number of clones or single isolates of many different clones have been obtained. The former situation is a good indication that the system is working well.

An important issue that arises in an interactor hunt is the question of how biologically relevant interacting proteins that are isolated are likely to be. This leads directly to the question of what K_d of association two molecules must have to be detected by an interactor hunt. In fact, this is not at all a simple issue. For the system described here, most fusion proteins appear to be expressed at levels ranging from 50 nM to 1 μM (Golemis and Brent, 1992). Given the strength of the *GAL* promoter, it is likely that many library-encoded proteins are expressed at similarly high levels, ≥1 μM in the nucleus (Golemis and Brent, 1992). At this concentration, which is in considerable excess over the nuclear concentration of operator-bound bait protein, a cDNA library–encoded protein should half-maximally occupy the DNA-bound bait protein if it possesses a K_d of 10^{-6} M, making it theoretically possible that very-low-affinity interactions could be detected. Such interactions have been observed in some cases. In contrast, some interactions that have been previously established using other methods and are predicted by known K_d to be easily detected by these means, either are not detected or are detected only weakly (Finley and Brent, 1994; Estojak et al., 1995). Because of the conservation of many proteins between lower and higher eukaryotes, one explanation for this observation is that either one or both of the partners being tested is being sequestered from the desired interaction by fortuitous association with an endogenous yeast protein. A reasonably complete investigation of the degree of correlation between in vitro determina-

BIU IAS CENTRAL UNIVERSITY LIBRARY

tions of interaction affinity and apparent strength of interaction in the interaction trap is included in Estojak et al. (1995). The result of this investigation suggests it is important to measure the affinity of detected interactions under different conditions, using a second assay system, rather than to draw conclusions about affinity based on detection in the interaction trap.

A number of different plasmids can be used for conducting an interactor hunt. Their properties are summarized in Tables 19.2.1 and 19.2.2. Because of the generous and open scientific exchange between investigators using the system, the number of available plasmids and other components has greatly expanded since the appearance of the initial two-hybrid reagents, facilitating the study of proteins inaccessible by the original system.

The original parent plasmid for generating LexA fusions, pEG202 is a derivative of 202 + PL (Ruden et al., 1991; see Fig. 19.2.3) that contains an expanded polylinker region. The available cloning sites in pEG202 include *Eco*RI, *Bam*HI, *Sal*I, *Nco*I, *Not*I, and *Xho*I, with the reading frame as described in the legend to Figure 19.2.3. Since the original presentation of this system, a number of groups have developed variants of this plasmid that address specialized research needs. Those currently available, as well as purposes for which they are suited, are listed in Table 19.2.1. pGilda, created by David A. Shaywitz, places the LexA-fusion cassette under the control of the inducible *GAL1* promoter, allowing expression of the bait protein for limited times during library screening, reducing the exposure of yeast to toxic baits. pJK202, created by Joanne Kamens, adds nuclear localization sequences to pEG202, facilitating assay of the function of proteins lacking internal nuclear localization sequences. pNLexA, created by Ian York, places LexA carboxy-terminal in the fusion domain, allowing assay of interactions that require an unblocked amino-terminus on the bait protein. pEE202I, created by Mike Watson and Rich Buckholz, allows chromosomal integration of a pEG202-like bait, thus reducing expression levels so they are more physiological for bait proteins normally present at low levels intracellularly. All of these have been extensively tested by numerous researchers. pGilda, pJK202, and pEE202I work with complete reliability. pNLexA works effectively with ~50% of the fusion domains tried, but synthesizes only very low levels of protein (relative to expression of the same fusion domain as a pEG202 fusion) with the remaining 50%. Attachment of fusion domains amino-terminal either to *LexA* or *GAL4* has been generally problematic in the hands of many investigators; it may be that appending additional protein sequences to the amino termini of these proteins is destabilizing, although the problem has not been rigorously investigated.

A series of *lacZ* reporters of differing sensitivity to transcriptional activation can be used to detect interactions of varying affinity (see Table 19.2.2). These plasmids are *LexA* operator–containing derivatives of the plasmid LR1Δ1 (West et al., 1984). In LR1Δ1, a minimal *GAL1* promoter lacking the *GAL1* upstream activating sequences (GAL_{UAS}) is located upstream of the bacterial *lacZ* gene. In pSH18-34, eight *LexA* operators have been cloned into an *Xho*I site located 167 bp upstream of the *lacZ* gene (S. Hanes, unpub. observ.). pJK103 and pRB1840 contain two and one operator, respectively.

pJK101 is similar to pSH18-34, except that it contains the *GAL1* upstream activating sequences (GAL_{UAS}) upstream of two *LexA* operator sites. A derivative of del20B (West et al., 1984), it is used in the repression assay (Brent and Ptashne, 1984; see Fig. 19.2.5) to assess LexA fusion binding to operator.

pSH17-4 is a *HIS3* 2μm plasmid that encodes LexA fused to the activation domain of the yeast activator GAL4. EGY48 cells bearing this plasmid will produce colonies in overnight growth on medium lacking Leu, and yeast that additionally contain pSH18-34 will turn deep blue on plates containing Xgal. This plasmid serves as a positive control for the activation of transcription.

pRFHM1 is a *HIS3* 2μm plasmid that encodes LexA fused to the N-terminus of the *Drosophila* protein bicoid. The plasmid has no ability to activate transcription, so EGY48 cells that contain pRFHM1 and pSH18-34 do not grow on –Leu medium and remain white on plates containing Xgal. pRFHM1 is a good control for specificity testing, because it has been demonstrated to be sticky—that is, to associate with a number of library-encoded proteins that are clearly nonphysiological interactors (R. Finley, Wayne State University, Detroit, Mich., unpub. observ.).

This protocol uses interaction libraries (Table 19.2.3) made in pJG4-5 or its derivatives (see Fig. 19.2.6). pJG4-5 was developed to facilitate isolation and characterization of novel proteins in interactor hunts (Gyuris et al., 1993). The pJG4-5 cDNA library expression

BOTANY/HERBARIUM LIBRARY

cassette is under control of the *GAL1* promoter, so library proteins are expressed in the presence of galactose (Gal) but not glucose (Glu). This conditional expression has a number of advantages, the most important of which is that many false-positives obtained in screens can be easily eliminated because they do not demonstrate a Gal-dependent phenotype. The expression cassette consists of an ATG to start translation, a nuclear localization signal to extend the interaction trap's range to include proteins that are normally predominantly localized in the cytoplasm, an activation domain (acid blob; Ma and Ptashne, 1987), the hemagglutinin epitope tag to permit rapid assessment of the size of encoded proteins, *Eco*RI-*Xho*I sites designed to receive directionally synthesized cDNAs, and the alcohol dehydrogenase (*ADH*) termination sequences to enhance the production of high levels of library protein. The plasmid also contains the *TRP1* auxotrophy marker and 2μm origin for propagation in yeast. A derivative plasmid, pJG4-5I, was created by Mike Watson and Richard Buckholz to facilitate chromosomal integration of the activation domain fusion expression plasmid.

A series of recently developed derivatives of pEG202, pJG4-5, and *lacZ* reporter plasmids (MW101 to MW112) alter the antibiotic resistance markers on these plasmids from ampicillin (Ap^r) to either kanamycin (Km^r) or chloramphenicol (Cm^r; Watson et al., 1996). Judiciously mixing and matching these plasmids in conjunction with Ap^r libraries would considerably reduce work subsequent to library screening, because the KC8 transformation, which involves *trpC* complementation in bacteria, could be omitted.

EGY48 and EGY191 (see Table 19.2.2) are both derivatives of the strain U457 (a gift of Rodney Rothstein, Columbia University, New York, N.Y.) in which the endogenous *LEU2* gene has been replaced by homologous recombination with *LEU2* reporters carrying varying numbers of *LexA* operators, using a procedure detailed in Estojak et al. (1995).

Interaction Trap–compatible reagents have recently become commercially available; Clontech and Invitrogen were the first to market such reagents and have recently been joined by OriGene. All suppliers use systems with the most sensitive reporters (EGY48 and pSH18-34), and provide their own positive and negative controls for testing activation or interaction between defined proteins. For expression of bait and library proteins, the Clontech Matchmaker LexA two-hybrid system and the OriGene Duplex-A system use some of the basic set of plasmids described here (see Table 19.2.1 for availability). Forward sequencing primers for bait and library plasmids are included in the Clontech kit, and Insert Screening Amplimer Sets for both plasmids can be acquired separately. Additional related products from Clontech include KC8 competent cells, anti-LexA monoclonal antibodies, a yeast transformation system, a yeast plasmid isolation kit, and an EGY48 partner strain for yeast mating to facilitate the analysis of interaction specificity. OriGene has a generally similar product line to Clontech. In contrast, Invitrogen has substantially modified the Interaction Trap core reagents to develop its own bait and library plasmids. pHybLex/Zeo, a novel bait plasmid, is ~50% smaller than the original pEG202 (making it easier to clone into), and it has an enriched polylinker. Significantly, it replaces both the Ap^r and *HIS3* genes with a novel gene that confers resistance to the antibiotic Zeocin (supplied with the kit), which provides selection in both bacteria and yeast. This elimination of auxotrophic selection for the bait plasmid renders the LexA-fusion construct usable with libraries and strains from all existing two-hybrid systems and additionally facilitates the direct selection of library plasmid in strains other than KC8. Some changes, which are designed to make the vector easier to use, have also been introduced in the library vector pYESTrp (e.g., it uses a V5 epitope tag for protein detection). The Invitrogen kit, termed Hybrid Hunter, includes the bait/library/reporter plasmids and EGY48 yeast strain as noted, and additionally includes primer sets for bait and library plasmids and the L40 yeast strain, should an investigator wish to use a *HIS3* auxotrophy selection. Additional related products from Invitrogen include antibodies for detection of bait and prey fusion proteins (anti-LexA and anti-V5), pJG4-5 library vector primers, and a Transformation Kit.

A significant advantage of the entry of commercial entities into the Interaction Trap field is the rapid increase in the number of compatible cDNA libraries. A list of currently available premade libraries available from these companies is presented in Table 19.2.3, and custom-made libraries are also available upon request. Because new libraries and other related reagents are being constantly added to the line of two-hybrid related products, it is advisable to contact the companies or visit their Web sites (*www.clontech.com, www.invitrogen.com,* and *www.origene.com*) for the latest information.

BIU IAS LIBRARY UNIVERSITY

Finally, over the last several years, a number of groups have adapted basic two-hybrid strategies to more specialized applications, and they have devised strategies to broaden their basic functionality. Interaction Mating (Finley and Brent, 1994) has been used to establish extended networks of targeted protein-protein interaction. In this approach, a panel of LexA-fused proteins are transformed into a *MATa* haploid selective strain (such as RFY206), a panel of activation-domain fused proteins are transformed into a suitable MATα haploid (such as EG448), and the two panels are cross-gridded against each other for mating. Selected diploids are then screened by replica plating to selective medium. This approach complements library screening in large-scale applications, such as proposed definition of interaction maps for entire genomes (Bartel et al., 1996).

Interaction mating has also provided the basis for an alternative two-hybrid hunt protocol (see Alternate Protocol 2), useful in cases when a single library will be screened with different baits. In this approach (Bendixen et al., 1994; Finley and Brent, 1994: Kolonin and Finley, 1998), a library is introduced into a single strain, like EGY48, and aliquots are stored frozen. To conduct a hunt, an aliquot is thawed and mated with a strain expressing a bait. This allows one to avoid repeated high-efficiency transformations, since a single library transformation can provide enough pretransformed yeast to conduct dozens of interactor hunts. Moreover, some yeast strains pretransformed with libraries are becoming commercially available, which may eliminate altogether the need to conduct a high-efficiency library transformation for some researchers.

Two-hybrid approaches have been shown to be effective in identifying small peptides with biological activities on selected baits (Yang et al., 1995; Colas et al., 1996), which may prove to be useful as a guide to targeted drug design. Rapid screening protocols have been devised using custom-synthesized libraries expressing sheared plasmid DNA to facilitate rapid mapping of interaction interfaces (Stagljar et al., 1996). Osborne and coworkers have demonstrated the effectiveness of a tribrid (or tri-hybrid) approach, in which an additional plasmid expresses a tyrosine kinase to specifically modify a bait protein, allowing detection of SH2-domain-containing partner proteins that recognize specific phosphotyrosine residues (Osborne et al., 1995). A variety of more elaborate tribrid approaches, in which a DNA-binding domain fused protein is used to present an intermediate nonprotein compound for interaction with a library, have been developed and proven effective. These approaches have allowed the identification of proteins binding specific drug ligands (Chiu et al., 1994; Licitra and Liu, 1996), as well as the identification of proteins binding to RNA sequences (SenGupta et al., 1996; Wang et al., 1996). It is expected that the range of utility of these systems will continue to expand.

Critical Parameters and Troubleshooting

To maximize chances of a successful interactor hunt, a number of parameters should be taken into account. Before attempting a screen, bait proteins should be carefully tested to ensure that they have little or no intrinsic ability to activate transcription. Bait proteins must be expressed at reasonably high levels and must be able to enter the yeast nucleus and bind DNA (as confirmed by the repression assay). Optimally, integrity and levels of bait proteins should be confirmed by immunoblot analysis, using an antibody to either LexA or the fused domain. In particular, at this time, bait proteins that have extensive transmembrane domains or are normally excluded from the nucleus are not likely to be productively used in a library screen. Proteins that are moderate to strong activators will need to be truncated to remove activating domains before they can be used.

If a protein neither activates nor represses, the most likely reason is that it is not being made. This can be determined by immunoblot analysis of a crude lysate protein extract of EGY48 (*UNIT 10.10*; Samson et al., 1989) containing the plasmid, using anti-LexA antibodies as primary antiserum. If the full protein is not made, it may be possible to express truncated derivatives of the protein. If the protein is made, but still does not repress, it may not enter the yeast nucleus effectively, although this appears to be a relatively rare problem. In this case, introducing the coding sequence for the fused moieity into a LexA fusion vector containing a nuclear localization motif (e.g., pJK202; J. Kamens, BASF, Worcester, Mass., unpub. observ.) may solve the problem.

The test for the leucine (Leu) requirement is extremely important to determine whether the bait protein is likely to yield an unworkably high background. The *LEU2* reporter in EGY48 is more sensitive than the pSH18-34 reporter for some baits (Estojak et al., 1995). Therefore, it is possible that a bait protein demonstrating little or no signal in a β-galac-

BOSTON CENTRAL UNIVERSITY LIBRARY

tosidase assay may nevertheless permit some growth on –Leu medium. If this occurs, there are several options. First, a less sensitive strain can be used, as described in the text. Second, background can sometimes be reduced further by making the EGY strain diploid (e.g., D. Krainc, Harvard Medical School, Boston, Mass.; R. Finley and R. Brent, unpub. observ.) or by performing the hunt by interaction mating as described in Alternate Protocol 2. A third option is to attempt to truncate the bait protein to remove activating function. In general, it is useful to extrapolate from the number of cells that grow on –Leu medium to the number that would be obtained in an actual library screen, and determine if this is a background level that can be tolerated. For example, if two colonies arise from 100,000 plated cells on –Leu medium, 200 to 400 would be expected in an actual screen of 10^6 cDNAs. Although this is a high initial number of positives, the vast majority should be eliminated immediately through easily performed controls. This is a judgment call. Finally, very rarely it happens that a bait that appears to be well behaved and negative for transcriptional activation through all characterization steps will suddenly develop a very high background of transcriptional activation following library transformation. The reason for this is currently obscure, and no means of addressing this problem has as yet been found: such baits are hence inappropriate for use in screens.

The protocols described in this unit use initial screening with the most sensitive reporters followed by substitution with less sensitive reporters if activation is detected. An obvious question is, why not start out working with extremely stringent reporters and know immediately whether the system is workable? In fact, some researchers routinely use a combination of pJK103 or pRB1840 with EGY191, and obtain proteins that to date appear to be biologically relevant partners from library screens. However, extensive comparison studies using interactors of defined in vitro affinity with different combinations of *LacZ* and *LEU2* reporters (Estojak et al., 1995) have indicated that although the most sensitive reporters (pSH18-34) may in some cases be prone to background problems, the most stringent reporters (EGY191, pRB1840) may miss some interactions that certainly are biologically relevant and occur inside cells. In the end, the choice of reporters devolves to the preference of individual investigators: the bias of the authors is to cast a broad net in the early stages of a screen, and hence to use more sensitive reporters when practicable.

It is important to move expeditiously through characterization steps and to handle yeast transformed with bait plasmids with care. In cases where yeasts have been maintained on plates for extended periods (e.g., 4 days at room temperature or >2 to 3 weeks at 4°C), unexpected problems may crop up in subsequent library screens.

The transformation protocol is a version of the lithium acetate transformation protocol described by Schiestl and Gietz (1989) and Gietz et al. (1992; see *APPENDIX 4L*) that maximizes transformation efficiency in *Saccharomyces cerevisiae* and produces up to 10^5 colonies/μg plasmid DNA. In contrast to *Escherichia coli*, the maximum efficiency of transformation for *S. cerevisiae* is ~10^4 to 10^5/μg input DNA. It is extremely important to optimize transformation conditions before attempting an interactor hunt. Perform small-scale pilot transformations to ensure this efficiency is attained and to avoid having to use prohibitive quantities of library DNA. In addition, as for any effort of this type, it is a good idea to obtain or construct a library from a tissue source in which the bait protein is known to be biologically relevant.

In practice, the majority of proteins isolated by interaction with a LexA fusion turn out to be specific for the fused domain; a smaller number are nonspecifically sticky, and to date there appears to have been only one isolation from a eukaryotic library of a protein specific for LexA. However, it is generally informative to retest positive clones on more than one LexA bait protein; ideally, library-derived clones should be tested against the LexA fusion used for their isolation, several LexA fusions to proteins that are clearly unrelated to the original fusion, and if possible, several LexA fusions that there is reason to believe are related to the initial protein (e.g., if the initial probe was LexA-Fos, a good related set would include LexA-Jun and LexA-GCN4).

Colony selection for master plate production is one of the more variable parts of the procedure. For strong interactors, colonies will grow up in 2 days. However, if plates are left at 30°C, new colonies will continue to appear every day. Those that appear rapidly are most likely to reflect interactors that are biologically relevant to the bait protein. Those that appear later may or may not be relevant. However, many parameters can delay the time of colony formation of cells that contain valid interactions, including the strength of the interaction

BIU IAS ISTANBUL UNIVERSITY LIBRARY

and the level of expression of the library-encoded protein.

Anticipated Results

Depending on the protein used as bait, anywhere from zero to hundreds of specific interactors will be obtained from 10^6 primary transformants.

Time Considerations

If all goes well, once the required constructions have been made it will take ~1 week to perform yeast transformations, obtain colonies, and determine whether bait proteins are appropriate. It will take a second week to perform library transformations, replate to selective medium, and obtain putative positives. A third week will be required to rescue the plasmid from the yeast, passage it through *E. coli*, transform fresh yeast, and confirm specificity.

Growth and Manipulation of Yeast

PREPARATION OF SELECTED YEAST MEDIA

Like *Escherichia coli*, yeast can be grown in either liquid media or on the surface of (or embedded in) solid agar plates. Yeast cells grow well on a minimal medium containing dextrose (glucose) as a carbon source and salts which supply nitrogen, phosphorus, and trace metals. Yeast cells grow much more rapidly, however, in the presence of protein and yeast cell extract hydrolysates, which provide amino acids, nucleotide precursors, vitamins, and other metabolites which the cells would normally synthesize de novo. During exponential or log-phase growth, yeast cells divide every 90 min when grown in such media.

Preparation of sterile media of consistently high quality is essential for the genetic manipulation of yeast. Autoclaving is usually carried out for 15 min at 15 lb/in^2, but times should be increased when large amounts of media are being prepared (20 min for 4 to 6 liters and 25 min for 6 to 12 liters).

Liquid Media

Ingredients for liquid media are dissolved in water to 1 liter, mixed until completely dissolved, and autoclaved in 100- or 500-ml media bottles. Alternatively, liquid media can be filter sterilized, resulting in faster preparation, less carmelization (of dextrose), and faster growth of cells. Recipes for "premixes" are provided to minimize the number of materials that must be weighed each time medium is prepared. When preparing premixes, break up any large chunks of dextrose before mixing with other components, then shake the container vigorously until contents are homogenized. It is convenient to make the premix in the empty plastic containers in which 2.5 kg of dextrose is packaged. Throughout this chapter, YNB –AA/AS refers to yeast nitrogen base without amino acids or ammonium sulfate. (See listing of recommended suppliers of ingredients in unit introduction above.)

Rich medium

YPD medium (YEPD medium)

Per liter:	*Premix:*	*Final concentration:*
10 g yeast extract	250 g yeast extract	1% yeast extract
20 g peptone	500 g peptone	2% peptone
20 g dextrose	500 g dextrose	2% dextrose
	Use 50 g/liter	

It is preferable to use a 20% (10×) solution of dextrose that has been filter sterilized or autoclaved separately (and added to the other ingredients after autoclaving) to prevent darkening of the media and to promote optimal growth.

Minimal media

Minimal medium [synthetic dextrose (SD) medium]

Per liter:	*Premix:*	*Final concentration:*
1.7 g YNB –AA/AS	68 g YNB –AA/AS	0.17% YNB –AA/AS
5 g $(NH_4)_2SO_4$	200 g $(NH_4)_2SO_4$	0.5% $(NH_4)_2SO_4$
20 g dextrose	800 g dextrose	2% dextrose
	Use 27 g/liter

BCU ASI / CENTRAL UNIVERSITY LIBRARY

This minimal medium can support the growth of yeast which have no nutritional requirements. However, it is used most often as a basal medium to which other supplements are added (see CM dropout medium below).

Complete minimal (CM) dropout medium, per liter

1.3 g dropout powder (Table A.4L.1)
1.7 g YNB –AA/AS
5 g $(NH_4)_2SO_4$
20 g dextrose
Alternatively, replace last three ingredients with 27 g minimal (SD) medium premix.

CM dropout powder, also known as minus or omission powder, lacks a single nutrient but contains the other nutrients listed in Table A.4L.1. Complete minimal (CM) dropout medium is used to test for genes involved in biosynthetic pathways and to select for gene function in transformation experiments. To test for a gene involved in histidine biosynthesis, determine if the yeast strain in question can grow on CM minus histidine (–His) or "histidine dropout" plates. It is convenient to make several dropout powders, each lacking a single nutrient, to avoid weighing each component separately for all the different dropout plates required in the laboratory.

It may be preferable to use a 10× solution of dropout powder (i.e., 13 g of dropout powder in 100 ml water) that has been "sterilized" separately (and added to the other ingredients after autoclaving) to improve the growth rate in this medium.

Table A4.L.1 Nutrient Concentrations for Dropout Powders[a]

Nutrient[b]	Amount in dropout powder (g)[c]	Final conc. in prepared media (μg/ml)	Liquid stock conc. (mg/100 ml)[d]
Adenine (hemisulfate salt)	2.5	40	500
L-arginine (HCl)	1.2	20	240
L-aspartic acid[e]	6.0	100	1200
L-glutamic acid (monosodium salt)	6.0	100	1200
L-histidine	1.2	20	240
L-leucine[f]	3.6	60	720
L-lysine (mono-HCl)	1.8	30	360
L-methionine	1.2	20	240
L-phenylalanine	3.0	50	600
L-serine	22.5	375	4500
L-threonine[e]	12.0	200	2400
L-tryptophan	2.4	40	480
L-tyrosine	1.8	30	180[f]
L-valine	9.0	150	1800
Uracil	1.2	20	240

[a]CM dropout powder lacks a single nutrient but contains the other nutrients listed in this table. Nomenclature in this manual refers to, e.g., a preparation that omits histidine as histidine dropout powder or CM medium –His. Conditions from Sherman et al. (1979).

[b]Amino acids not listed here can be added to a final concentration of 40 μg/ml (40 mg/liter).

[c]Grind powders into a homogeneous mixture with a clean, dry mortar and pestle. Store in a clean, dry bottle or a covered flask.

[d]Use 8.3 ml/liter of each stock for special nutritional requirements. Store adenine, aspartic acid, glutamic acid, leucine, phenylalanine, tyrosine, and uracil solutions at room temperature. All others should be stored at 4°C.

[e]Although these amino acids can be used reliably when included in autoclaved media, they supplement growth better when added after autoclaving.

[f]Use 16.6 ml/liter for L-tyrosine nutritional requirement.

BCU IASI CENTRAL UNIVERSITY LIBRARY

Solid Media

For all plates, agar is added at a concentration of 2% (20 g/liter). A pellet of sodium hydroxide (~0.1 g) should be added per liter to raise the pH enough to prevent agar breakdown during autoclaving. In addition, add a stir bar to facilitate mixing after autoclaving. After autoclaving, flasks are left for 45 to 60 min at room temperature until cooled to 50° to 60°C. (Drugs and other nutrients are added after 30 min at room temperature.) Just prior to pouring, put the flask on a stir plate at medium to high speed and mix until contents are homogeneous (~5 min). After pouring, a few bubbles can be removed from the agar surface by passing the flame of a Bunsen burner lightly over the surface of the molten agar ("flaming" the plates). One liter of medium will yield 30 to 35 plates.

Most plates can be stored at room temperature for ≤4 months. Plates containing drugs (cycloheximide, 5-fluoroorotic, canavanine, and L-α-aminoadipic acid) or 5-bromo-4-chloro-3-indolyl-β-D-galactosidase (Xgal; 20 μg/ml; *APPENDIX 4A*) are stable for 2 to 3 months when stored at 4°C.

Minimal plates and rich plates

YPD, minimal, and CM dropout plates

Per liter: Follow recipes for liquid medium above, adding 20 g agar and a pellet of NaOH.

Premixes: Follow recipes for liquid medium premixes above, adding 500 g agar for YPD premix and 800 g agar for minimal premix. To prepare plates, add one NaOH pellet and the following amounts of premix (per liter):

YPD plates—70 g YPD plate premix
Minimal plates—47 g minimal plate premix
CM dropout plates—47 g minimal plate premix + 1.3 g dropout powder

Specialty plates

Xgal plates, per liter

1.7 g YNB –AA/AS
5 g $(NH_4)_2SO_4$
20 g dextrose
20 g agar
0.8 g dropout powder (omitting appropriate amino acids; see Table A4.L.1)
NaOH pellet
(Alternatively, replace first four ingredients with 47 g minimal plate premix.)

Add H_2O to 900 ml and autoclave. Add 100 ml of 0.7 M potassium phosphate, pH 7.0, and 2 ml of 20 mg/ml Xgal prepared in 100% *N,N*-dimethylformamide (stored as frozen stock).

STRAIN STORAGE AND REVIVAL

Yeast strains can be stored at –70°C in 15% glycerol (viable for >5 years), or at 4°C on slants consisting of rich medium supplemented with potato starch (viable for 1 to 2 years).

Preparation and Inoculation of Frozen Stocks

Make a solution of 30% (w/v) glycerol. Pipet 1 ml into 15 × 45–mm, 4-ml screw-cap vials. Loosely cap the vials and autoclave 15 min.

To inoculate vials for storage, add 1 ml of a late-log or early-stationary phase culture, mix, and set on dry ice. Store at –70°C. Revive by scraping some of the cells off the frozen

BC VIAS / CENTRAL UNIVERSITY LIBRARY

surface and streak onto plates. Do not thaw the entire vial. Cells can also be stored in the same way by adding 80 µl dimethyl sulfoxide (DMSO) to 1 ml cells (8% v/v) and storing at –70°C.

BASIC PROTOCOL 1

ASSAY FOR β-GALACTOSIDASE IN LIQUID CULTURES

Materials

YPD medium (see recipe under Liquid Media)
Z buffer (see recipe in Reagents and Solutions)
0.1% sodium dodecyl sulfate (SDS)
Chloroform
4 mg/ml *O*-nitrophenyl-β-D-galactoside (ONPG) in 0.1 M potassium phosphate, pH 7.0 (see *APPENDIX 2E* for buffer; filter sterilize and store frozen)
1 M Na_2CO_3
30°C water bath

1. Inoculate 5 ml YPD (or appropriate) medium with single yeast colony. Grow 2 to 3 independent single-colony cultures of a strain containing *lacZ* fusion protein overnight at 30°C. If fusion is on a plasmid, grow cells in medium that selects for plasmid.
2. Inoculate 5 ml YPD medium (or appropriate selective medium and/or inducing conditions) with 20 to 50 µl of each overnight culture. Grow to mid- or late-log phase: 0.5–1 × 10^8 cells/ml (OD_{600} = 2.0) for rich medium or 2–5 × 10^7 cells/ml (OD_{600} = 0.5 to 1.0) for minimal medium.

   If goal is to investigate activity of yeast promoter under conditions that induce its expression, grow cells in parallel under inducing and noninducing conditions.

3. Centrifuge cells 5 min at 1100 × *g*. Resuspend in equal volume of Z buffer and place on ice. Determine OD_{600} for each sample.

   If anticipated level of β-galactosidase activity is low, it may be necessary to concentrate cells. For cells demonstrating 100 to 1000 U of activity within 30 min to 4 hr, concentration is not necessary.

4. Set up the following two reaction tubes for each sample (1 ml each), with mixing: (a) 100 µl cells with 900 µl Z buffer and (b) 50 µl cells with 950 µl Z buffer.
5. Add 1 drop of 0.1% SDS and 2 drops chloroform to each sample using a Pasteur pipet. Vortex 10 to 15 sec and equilibrate 15 min in 30°C water bath.
6. Add 0.2 ml of 4 mg/ml ONPG; vortex 5 sec. Place in 30°C water bath and begin timing. When medium-yellow color (OD_{420} = 0.3 to 0.7) has developed, add 0.5 ml of 1 M Na_2CO_3 and note time.
7. Centrifuge cells 5 min at 1100 × *g*. Determine OD_{420} and OD_{550} of supernatant.

   If the cell debris has been well pelleted, the OD_{550} is usually zero and therefore is not necessary to read.

8. Calculate units with the following equation:

$$U = \frac{1000 \times [(OD_{420}) - (1.75 \times OD_{550})]}{(t) \times (v) \times (OD_{600})}$$

where t = time of reaction (min); v = volume of culture used in assay (ml); OD_{600} = cell density at the start of the assay; OD_{420} = combination of absorbance by *o*-ni-

BCU IASI / CENTRAL UNIVERSITY LIBRARY

trophenol and light scattering by cell debris; and OD_{550} = light scattering by cell debris.

TRANSFORMATION USING LITHIUM ACETATE

BASIC PROTOCOL 2

This is the most commonly used method for yeast transformation. It is reasonably fast and provides transformation efficiencies of 10^5 to 10^6 transformations/µg.

NOTE: All solutions and glassware coming into contact with yeast cells must be sterile. Traces of soap on glassware may decrease the transformation efficiency. In addition, the water used for washes and in solution preparation must be of the highest quality.

Materials

YPD medium (see recipe under Liquid Media)
Yeast strain to be transformed
YPAD medium: YPD medium supplemented with 30 mg/liter adenine hemisulfate
Highest-quality sterile H_2O
10× TE buffer, pH 7.5 (see *APPENDIX 2E* for 1× recipe), sterile
10× lithium acetate stock solution: 1 M lithium acetate, pH 7.5 (adjust pH with dilute acetic acid), filter sterilized
DNA: high-molecular-weight, single-stranded carrier DNA and transforming DNA
50% (w/v) polyethylene glycol (PEG 4000 or 3350 (do not use PEG 8000), filter sterilized
CM dropout plates (see recipe under Solid Media) prepared with Difco agar

30°C incubator with shaker
Sorvall GSA and SS-34 rotors (or equivalents)
42°C water bath

1. Two days before the experiment, inoculate 5 ml YPD medium with a single yeast colony of the strain to be transformed. Grow overnight to saturation at 30°C.
2. The night before transformation, inoculate a 1-liter sterile flask containing 300 ml YPAD medium with an appropriate amount of the saturated culture and grow overnight at 30°C to 1×10^7 cells/ml ($OD_{600} \cong 0.3$ to 0.5, depending on strain). For 2- to 3-fold higher efficiency, dilute at this point to 2×10^6 cells/ml in fresh YPAD medium and grow for another 1 to 2 generations (2 to 4 hr).

   Because growth phase and cell density are important in achieving the highest transformation efficiency, the easiest approach is to inoculate three independent flasks with varying amounts of the saturated overnight culture (try 1, 5, and 25 µl for a 12-hr growth period), then check the OD_{600} of each flask the next day.

3. Harvest cells by centrifuging 5 min at 4000 × *g*, room temperature. Resuspend in 10 ml highest-quality sterile water. Transfer to a smaller centrifuge tube and pellet cells by centrifuging 5 min at 5000 to 6000 × *g*, room temperature.
4. Resuspend in 1.5 ml buffered lithium solution, freshly prepared as follows:

   1 vol 10× TE buffer, pH 7.5
   1 vol 10× lithium acetate stock solution
   8 vol sterile water.

5. For each transformation, mix 200 µg carrier DNA with ≤5 µg transforming DNA in a sterile 1.5-ml microcentrifuge tube. Keep total volume of DNA ≤20 µl.

   Maximal transformation efficiency is achieved by repeating the denaturation cycle (boiling and chilling) of carrier DNA immediately prior to use.

6. Add 200 µl yeast suspension to each microcentrifuge tube. Add 1.2 ml PEG solution, freshly prepared as follows:

BCU AGHAEGRE UNIVERSITY LIBRARY

8 vol 50% PEG
1 vol 10× TE buffer, pH 7.5
1 vol 10× lithium acetate stock solution.

Shake 30 min at 30°C.

7. Heat shock exactly 15 min at 42°C. Microcentrifuge 5 sec at room temperature. Resuspend yeast in 200 µl to 1 ml of 1× TE buffer (freshly prepared from 10× stock) and spread up to 200 µl onto CM dropout plates made with Difco agar. Incubate 2 to 5 days at 30°C until transformants appear.

REAGENTS AND SOLUTIONS

Use Milli-Q water or equivalent in all recipes and protocol steps. For common stock solutions, see ***APPENDIX 2E****; for suppliers, see* ***SUPPLIERS APPENDIX****.*

Z buffer

16.1 g $Na_2HPO_4 \cdot 7H_2O$ (60 mM final)
5.5 g $NaH_2PO_4 \cdot H_2O$ (40 mM final)
0.75 g KC1 (10 mM final)
0.246 g $MgSO_4 \cdot 7H_2O$ (1 mM final)
2.7 ml 2-mercaptoethanol (50 mM final)
Adjust to pH 7.0 and bring to 1 liter with H_2O
Do not autoclave

SUPPLEMENT INDEX

How to Use This Index

A new main index is provided once a year. Thereafter, with the next three supplements, a cumulative supplement index, which amends the main index, will be provided. Thus, readers should consult both the main index and the supplement index when seeking an entry, as page numbers may change for replacement units and new entries will added.

A

Absorption spectroscopy, quantitation of nucleic acids using, APPENDIX 4K
Acid blob domain
  expression cassette containing, 19.2.36
  protein fusions to, 19.2.1
Activation domain, acid blob, 19.2.36
Activator protein GLA4, fusion with LexA, 19.2.8
Adsorption, and elution location, GF chromatography, 8.3.29
Affinity, of proteins in interactions, 8.3.1
Agarose, gel electrophoresis, APPENDIX 4F
Air bubbles, GF column, causes and removal of, 8.3.28–8.3.29
Alcohol dehydrogenase (ADH), promoter pEG202, 19.2.7
Ammonium sulfate, protein precipitation using
  basic theory, A.3F.1
  common applications, A.3F.1–A.3F.3
  tables, A.3F.3–A.3F.7
Amplification
  enzymatic of DNA, by PCR, A.4J.2–A.4J.5
  of recombinant vaccinia virus, 5.13.12–5.13.13
Antibiotic resistance, plasmid markers for, alteration of, 19.2.36
Association rate constant k_{assoc}, 19.1.3–19.1.4

B

Bacterial colonies, growth in media
  isolating single colonies
    by spreading a plate, A.4B.2
    by streaking a plate, A.4B.2
  isolating and titering bacterial colonies by serial dilutions, A.4B.2
  larger cultures, A.4B.1
  monitoring, A.4B.1
  overnight cultures, A.4B.1
  replica plating, A.4B.3
  strain storage and revival, A.4B.3
Bait protein
  characterizing, 19.2.3–19.2.11
  immunoblot analysis, for fusion protein, 19.2.10
  interactor hunts with, multiple simultaneous, using interaction mating, 19.2.23
  plasmid pEG202 for expressing, 19.2.1
  testing, 19.2.37
  toxic
    alternate hunt with interaction mating, 19.2.23
    reducing exposure of yeast to, 19.2.35
Bed compression, GF chromatography, 8.3.28
Biological effects, equilibrium and kinetic considerations in, 19.1.4
Buffers, *see* Reagents and Solutions
Butanol, in DNA precipitation, A.4E.2

C

Calcium chloride, introduction of plasmid DNA into cells using, A.4D.1
Calibration, GF chromatography
  maintenance of, 8.3.28
  standards for, 8.3.22
  molecular size determination, 8.3.19–8.3.21, 8.3.24 (table)
cDNA library
  expression cassette, pJG4-5, 19.2.35–19.2.36
  screening, 19.2.34
Chicken embryo fibroblasts (CEF), preparation of modified vaccinia virus (MVA) stock, 5.12.6–5.12.10
Cloning sites, in pEG202, 19.2.35
Collision-induced dissociation fragment ions, low-energy, 16.3.1
Columns, GF chromatography
  calibration, for molecular size determination, 8.3.19–8.3.21
  packing
    general instructions, 8.3.8–8.3.10
    for protein fractionation, 8.3.14–8.3.15
    for molecular size determination, 8.3.17–8.3.18
Complete minimal dropout medium, for yeast growth (recipes)
  powder and liquid medium, A.4L.2
  plates, A.4L.3

D

Databases
  protein, 16.5.1
  sequence
    search with MS-Fit, UNIT 16.5
    search with MS-Tag, UNIT 16.6
Dead time, in GF chromatography, utilizing, 8.3.26
Dead volume, GF chromatography, tailing peaks as an indication of, 8.3.29
Denaturation, for molecular size determination, 8.3.19, 8.3.21
Desalting (group separation)
  GF chromatography, 8.3.1–8.3.2, 8.3.6–8.3.13
  GF buffer preparation, 8.3.22–8.3.23
  matrix characteristics, empty and prepacked column, 8.3.3 (table)
  optimization and scaleup, 8.3.25
  yield in, 8.3.26
Dextran reference standard, molecular size of proteins, 8.3.19
2,5-Dihydroxybenzoic acid (DHB), matrix for MALDI-MS, 16.3.1
Dissociation constants for protein-protein interactions, 19.1.2 (table)
Dissociation rate constant k_{dissoc}, 19.1.3
Distribution coefficient K_D, GF chromatography, 8.3.20
DNA
  binding by, repression assay for, 19.2.9 (fig.)
  butanol precipitation of, A.4E.2
  digestion with restriction endonucleases
    restriction endonuclease buffers, A.4I.3
    single sample with single restriction endonuclease, A.4I.1–A.4I.3
  enzymatic amplification of, by PCR, A.4J.2–A.4J.5
  ethanol precipitation of, A.4E.1
  phenol extraction of, A.4E.1
  plasmid, *see* Plasmid DNA
  purification and concentration
    agarose gel electrophoresis, A.4F.1–A.4F.2
    from aqueous solutions, A.4E.1–A.4E.2
  recombinant vaccinia virus, 5.13.8–5.13.9
  replication, kinetics of, 19.1.4
  shearing, by sonication, 19.2.28–19.2.29

Current Protocols in Protein Science

Supplement 15 **New and Revised Topics** **March 1999**

In this Supplement ...

☑ Sequence Similarity Searching Using the BLAST Family of Programs *(New)* UNIT 2.5

☑ Ion-Exchange Chromatography *(New)* UNIT 8.2

☑ Enzymatic Approaches for Obtaining Amino Acid Sequence: On-Target Ladder Sequencing *(New)* UNIT 16.7

☑ Native Chemical Ligation of Polypeptides *(New)* UNIT 18.4

☑ Phage-Based Expression Cloning to Identify Interacting Proteins *(New)* UNIT 19.3

Coming soon ...

☑ Characterizing Recombinant Proteins Using Gel-Filtration HPLC and Mass Spectrometry *(New)*

☑ Peptide Demdrimers as Protein Mimetics *(New)*

This supplement includes important new topics to bring your CPPS subscription up to date with the latest methodology. Also included is a reader response card for forwarding us your comments and suggestions. Please see next page for a full listing of contents and instructions for inserting pages.

For more detailed information about new and upcoming topics, please visit the Current Protocols Home Page at *www.wiley.com/cp.*

Routing List

After filing, you may wish to route this cover sheet to other Current Protocols users to keep them informed of the new topics.

Sequence Similarity Searching Using the BLAST Family of Programs

Database sequence similarity searching is carried out thousands of times each day by researchers worldwide. Scientists in traditional laboratories use search results, for example, to infer the functions of newly discovered cDNAs, predict new members of gene families, and explore evolutionary relationships between sequences. In turn, they populate sequence databases with biochemically and/or genetically characterized sequences. With the advent of whole-genome sequencing, a new breed of scientist is now using these characterized sequences to predict the location and function of coding and regulatory regions in large segments of genomic DNA. Their contribution to the sequence databases is the submission, at a rapid pace, of generally uncharacterized mRNA and genomic DNA sequences. These data can then be used by the first group of scientists to enhance the understanding of their sequences. Both types of sequencing efforts have greatly increased the size and quality of the sequence databases in recent years. Thus, sequence similarity searching has become a valuable research tool for all molecular biologists (Altschul et al., 1994; Schuler, 1998; also see *UNIT 2.1*).

Over the years, a number of algorithms have been implemented that allow searching of sequence databases. The most useful of these tools should share the following characteristics: (1) Speed. Because today's databases are so large, the programs must be fast in order to process megabases of sequence in seconds. (2) Sensitivity. The programs must report all potentially interesting similarities. (3) Rigorous statistics. The programs must provide a way to evaluate the significance of the results. (4) Ease of use. Scientists with no formal training in sequence-analysis algorithms should understand how to use the programs and interpret the results. Advanced users should have the option to tailor the programs to their needs. (5) Access to up-to-date databases. The doubling time of GenBank is currently ~16 months. It is important to search the most recent version of the database.

The BLAST (Basic Local Alignment Search Tool) family of sequence similarity search programs satisfies the above criteria. In short, users input either a nucleotide or amino acid query sequence, and search a nucleotide or amino acid sequence database. The program returns a list of the sequence "hits," alignments to the query sequence, and statistical values. This unit describes how to choose an appropriate BLAST program and database, perform the search, and interpret the results.

ACCESSING BLAST PROGRAMS AND DOCUMENTATION

The National Center for Biotechnology Information (NCBI) currently supports two versions of BLAST free of charge: BLAST 2.0 (gapped BLAST) and Position-Specific Iterated BLAST (PSI-BLAST). BLAST 2.0 is the standard version of BLAST, which allows a user to search a sequence database with a nucleotide or protein sequence of interest. BLAST 2.0 places gaps into the query and target sequences so that separate areas of similarity between the two sequences can be returned as one hit. PSI-BLAST is an iterative BLAST search, which is optimized for finding distantly related sequences.

Other BLAST programs are also available from the NCBI Web page. "BLAST 2 sequences" uses the BLAST search engine to produce an alignment of two sequences entered by the user. On the Specialized BLAST pages, researchers can use the BLAST engine to search sequences that are not in GenBank. At present, these databases include unfinished microbial genomes, *P. falciparum* (the human malaria parasite), and tentative

BOSTON UNIVERSITY MEDICAL CENTRAL LIBRARY

human consensus (THC) sequences from The Institute for Genomic Research (TIGR). The content of these pages is, however, subject to change.

The easiest and most popular way to access the BLAST suite of programs is through the NCBI World Wide Web site, at *http://www.ncbi.nlm.nih.gov/BLAST/*. All versions of BLAST are accessible from this site, and can be used to query all sequence databases available at the NCBI. Documentation, which includes an overview of BLAST, BLAST frequently asked questions (FAQs), a "What's New" page, the BLAST manual, and a list of references, is also available here.

For users who want to run BLAST against private local databases or downloaded copies of NCBI databases, the NCBI offers a stand-alone version of the BLAST program. BLAST binaries and documentation are provided for the latest versions of IRIX, Solaris, DEC OSF1, and Win32 systems. BLAST 2.0 executables may be found on the NCBI anonymous FTP server at *ftp://ncbi.nlm.nih.gov/blast/executables/*.

BLAST can also be run as a client-server program, in which the user installs client software on a local machine that communicates across the network with a server at NCBI. This setup is useful for researchers who run large numbers of searches on NCBI databases, because they can automate the process to run on their local computer. The BLAST client may be found on the NCBI anonymous FTP server at *ftp://ncbi.nlm.nih.gov/blast/network/netblast*.

The NCBI BLAST e-mail server is the best option for people without convenient access to the Web. A similarity search can be performed by sending a properly formatted e-mail message containing the nucleotide or protein query sequence to *blast@ncbi.nlm.nih.gov*. The query sequence is compared against a specified database and the results are returned in an e-mail message. For more information on formulating e-mail BLAST searches, please send a message consisting of the word HELP to the same address, *blast@ncbi.nlm.nih.gov*.

This unit concentrates on the BLAST searches which can be performed from the NCBI Web site. The other implementations are mainly for advanced users of BLAST, or those with special needs. For any of these services, questions should be directed to *blast-help@ncbi.nlm.nih.gov*.

INTRODUCTION TO BLAST

Basic Versus Advanced BLAST Searches

BLAST 2.0 is available in a basic or advanced version. In both versions, the user can select the type of BLAST program and the database to be searched, and choose whether to filter the query sequence to mask low-complexity regions (see below). The advanced version allows the user to change parameters as well. For most researchers, the Basic version, which uses the default parameters, is adequate. For a discussion of BLAST parameters, see Appendix A at the end of this unit.

BLAST Programs

Five types of the BLAST program have been developed to support sequence similarity searching using a variety of nucleotide and protein sequence queries and databases. These programs are listed and described in Table 2.5.1. The type of BLAST search to be carried out is dependent on the type of information that is desired.

BCU IAS CENTRAL UNIVERSITY LIBRARY

Table 2.5.1 BLAST Search Programs

Program	Query sequence	Database sequence	Comments
BLASTP	Protein	Protein	Can be run in standard mode or in a more sensitive iterative mode (PSI-BLAST), which uses the previous search results to build a profile for subsequent rounds of similarity searching.
BLASTN	Nucleotide (both strands)	Nucleotide	Parameters optimized for speed, not sensitivity; not intended for finding distantly related coding sequences. Automatically checks complementary strand of query.
BLASTX	Nucleotide (six-frame translation)	Protein	Very useful for preliminary data containing potential frameshift errors (ESTs, HTGs, and other "single-pass" sequences).
TBLASTN	Protein	Nucleotide (six-frame translation)	Essential for searching protein queries against EST database. Often useful for finding undocumented open reading frames or frameshift errors in database sequences.
TBLASTX	Nucleotide (six-frame translation)	Nucleotide (six-frame translation)	Should be used only if BLASTN and BLASTX produce no results. Restricted for search against EST, STS, HTGS, GSS, and Alu databases.

NCBI Databases

One frequent mistake in sequence similarity searching is failure to search an up-to-date database. The NCBI produces GenBank (Benson et al., 1998; *ftp://ncbi.nlm.nih.gov/genbank/gbrel.txt*) and updates it daily. It also shares data on a daily basis with the DNA Data Bank of Japan (DDBJ; Tateno et al., 1998) and the European Molecular Biology Laboratory (EMBL; Stoesser et al., 1998). A search of the NCBI databases using the BLAST Web page, client, or e-mail server guarantees access to the most recent database. The NCBI supports a number of databases for sequence similarity searching. These databases are subject to change, and a current list and description are available on the NCBI Web site at *http://www.ncbi.nlm.nih.gov/BLAST/blast_databases.html*. This section describes some of the commonly used NCBI databases. Examples demonstrating the utility of various BLAST programs and NCBI databases are given in the next section.

Peptide sequence databases for BLASTP and BLASTX

nr. The nr (nonredundant) database is the most comprehensive. GenBank, DDBJ, and EMBL are nucleotide sequence databases. If any nucleotide sequence in any of the databases is annotated with a coding sequence (CDS), this CDS appears in nr. nr also contains protein sequences obtained from PDB (sequences associated with 3-dimensional structures in the Brookhaven Protein Data Bank), Swiss-Prot (a curated database of protein sequences; Bairoch and Apweiler, 1998), PIR (Protein Identification Resource, a comprehensive collection of protein sequences; Barker et al., 1998), and PRF (Protein Research Foundation). Although nr may contain multiple copies of similar sequences, identical sequences are merged into one entry. To be merged, two sequences must have identical lengths and every residue at every position must be the same. There are nr databases for both peptide and nucleotide sequences. The peptide database is automatically selected for BLASTP and BLASTX searches.

BOSTON BIOMEDICAL RESEARCH INSTITUTE LIBRARY

month. The month database receives its sequences from the same sources as nr, but contains only those sequences released within the last 30 days. All sequences in month are also present in nr.

Alu. The Alu database contains six-frame translations of representative *Alu* repeats from all *Alu* subfamilies (Claverie and Makalowski, 1994). If a query sequence containing an *Alu* repeat is used in a BLAST search of nr or month, many of the resulting high-scoring hits will also contain *Alu* sequences. It may be useful, especially with a genomic sequence query, to perform a search of the Alu database to identify the location of any *Alu* repeats that might produce high-scoring and potentially misleading hits in queries of other databases.

Nucleotide sequence databases for BLASTN, TBLASTN, and TBLASTX

nr. The nr (nonredundant) database contains all nucleotide sequences present in GenBank, EMBL, and DDBJ. It also contains nucleotide sequences obtained from PDB (sequences associated with 3-dimensional structures in the Brookhaven Protein Data Bank). nr comprises only sequences that are normally well annotated, so it does not contain expressed sequence tag (EST), sequence-tagged site (STS), genome survey sequence (GSS), or high-throughput genomic (HTG) sequences. Although nr may contain multiple copies of similar sequences, identical sequences are merged into one entry. To be merged, two sequences must have identical lengths and every nucleotide at every position must be the same.

month. The month database contains all nucleotide sequences present in GenBank, EMBL, DDBJ, and PDB that were released within the last 30 days. Unlike nr, it also contains EST, STS, GSS, and HTG sequences released within the last month.

EST. EST accesses a nonredundant copy of all ESTs present in GenBank, EMBL, and DDBJ (Boguski et al., 1993). ESTs are short sequences, a few hundred nucleotides in length, which are derived by partial, single-pass sequencing of inserts of randomly selected cDNA clones (Adams et al., 1991). Since the number of ESTs is increasing rapidly, it is an important database to search for novel cDNAs. As of August, 1998, ~70% of the sequences in GenBank were ESTs; of these, 61% were from human, 20% from mouse.

STS. STS contains a nonredundant copy of all STSs present in GenBank, EMBL, and DDBJ. An STS is a short unique genomic sequence that is used as a sequence landmark for genomic mapping efforts (Olson et al., 1989). As of August, 1998, 83% of the sequences in the STS database were from human.

HTGS. HTGS contains "unfinished" DNA sequences generated by the high-throughput sequencing centers (Ouellette and Boguski, 1997). A typical HTG record might consist of all the first-pass sequence data generated from a single cosmid, BAC, YAC, or P1 clone. The record is composed of two or more sequence fragments that have a total length of ≥2 kb and contain one or more gaps. The sequences are normally updated by the sequencing centers as more data become available. A single accession number is assigned to this collection of sequences. The accession number does not change as the record is updated, and only the most recent version of the record remains in GenBank. Phase 1 HTG sequences are unordered, unoriented contigs with gaps. Phase 2 HTG sequences are ordered, oriented contigs with or without gaps. All HTG records contain a prominent warning that the sequence data is unfinished and may contain errors. When a record is considered finished, it becomes a Phase 3 HTG and is moved to the nr database with the same accession number. HTGS is a valuable source of new genomic sequences not yet in nr.

BCU IASI CENTRAL UNIVERSITY LIBRARY

GSS. GSS includes short, single-pass genomic data identified by various means (Smith et al., 1994). Many of the sequences have been mapped. As of August, 1998, 80% of the sequences in GSS were from human, 14% from *Arabidopsis thaliana.*

*Alu.*The Alu database contains representative *Alu* repeats from all *Alu* subfamilies (Claverie and Makalowski, 1994). If a query sequence containing an *Alu* repeat is used in a BLAST search of the above nucleotide databases, many of the resulting high-scoring hits will also contain *Alu* sequences. It may be useful, especially with a genomic sequence query, to perform a search of the Alu database to identify the location of any *Alu* repeats that might produce high-scoring and potentially misleading hits in queries of other databases.

Vector. The Vector database contains nucleotide sequences of a number of standard cloning vectors. New sequences should be screened against the Vector database to assure that they do not contain any vector contamination.

Mito. The Mito database contains representative mitochondrial sequences from many families. Nuclear-derived sequences may be screened against the Mito database to assure that they do not contain any mitochondrial contamination.

Formatting the Query Sequence

Users of the BLAST Web page can initiate a search either by entering the sequence itself, or, if the sequence is already in the sequence database, by entering the accession number or gi (see Appendix B at the end of this unit). The preferred format for entering new sequences is the so-called FASTA format; however, if the sequence is not in FASTA format or the sequence is interspersed with numbers and spaces, BLAST will still accept the query. A sequence in FASTA format begins with a single-line description, followed by lines of sequence data. The description line is distinguished from the sequence data by a > symbol (greater than) in the first column. An example sequence in FASTA format is:

```
>aaseq Human choroideremia protein
MADNLPTEFDVVIIGTGLPESILAAACSRSGQRVLHIDSRSYYGGNWASFSFSGLLSWLKEYQQNNDIGE
ESTVVWQDLIHETEEAITLRKKDETIQHTEAFPYASQDMEDNVEEIGALQKNPSLGVSNTFTEVLDSALP

VTELCSSTMTCMKDTYLVHLTCSSSKTAREDLESVVKKLFTPYTETEINEEELTKPRLLWALYFNMRDSS
GISRSSYNGLPSNVYVCSGPDCGLGNEHAVKQAETLFQEIFPTEEFCPPPPNPEDIIFDGDDKQPEAPGT
NNVVMAKLESSEESKNLESPEKHLQN
```

Alternatively, the user can enter the database accession number or gi. The above sequence is in fact already in the database with a gi identifier of 116365 and a Swiss-Prot accession number of P26374. Either of these sequence identifiers can be entered on the BLAST page. The type of identifier (for nucleotide or protein sequence) must match the type of query sequence used in that search (Ostell and Kans, 1998; Ouellette, 1998). Sequences in manuscripts are often referred to by their GenBank accession number; however, this accession number refers to a nucleotide (not protein) sequence, and cannot be used to initiate a BLASTP or TBLASTN search, both of which require a protein sequence query. The identifier of the protein sequence encoded by a nucleotide accession number can be obtained by searching the NCBI's Entrez nucleotide database, at *http://www.ncbi.nlm.nih.gov/Entrez.*

BOSTON UNIVERSITY LIBRARY

Filtering Sequences

Both nucleotide and protein sequences may contain regions of low complexity, i.e., regions with homopolymeric tracts, short-period repeats, or segments enriched in one or only a few residues. Such low-complexity regions commonly give spuriously high BLAST scores that reflect compositional bias rather than significant position-by-position alignment (Altschul et al., 1994). For example, two protein sequences that contain low-complexity regions rich in the same amino acids may produce high-scoring alignments in those regions even though other parts of the proteins are entirely dissimilar. Because these alignments do not reflect a common ancestry, no functional inference is justified despite their high statistical significance. Filtering the query sequence (that is, replacing the repeated sequence with strings of n for nucleotide sequence or X for protein sequence) can eliminate potentially confounding matches, such as hits to low-complexity, proline-rich regions or poly(A) tails present in the database.

By default, all searches performed through the NCBI BLAST Web page automatically filter the query sequence, as do the BLAST clients, e-mail server, and stand-alone programs. However, filtering can be turned off, even on the Basic BLAST page. Filtered sequence is represented in the final BLAST report as a string of n or X (e.g., nnnnnnnnnn or XXXXXXXXX). BLASTN queries are filtered with DUST (R.L. Tatusov and D.J. Lipman, pers. comm.). Other BLAST queries use SEG (Wootton and Federhen, 1993, 1996).

Viewing the BLAST Results

The NCBI BLAST Web page can return results in one of three ways. The default is to display the results in the browser window from which the user initiated the search. The document will have hypertext links that make it easier to analyze the results. BLAST queries are processed in the order in which they are received, except that less computationally intensive jobs (e.g., BLASTN, BLASTP, and smaller databases such as month) are given priority. In the middle of the afternoon, the BLAST server may be busy. Thus, it is sometimes more efficient to receive the BLAST results by e-mail. E-mail results are sent either as plain text or in HTML format. The HTML-formatted results must be opened in a Web browser, and the resulting document contains hypertext links.

EXAMPLES OF BLAST SEARCHES

In this section, interpretation of BLAST results is explained using examples for BLASTP, BLASTX, TBLASTN, BLASTN, and PSI-BLAST. An example is not shown for TBLASTX, as it is a tool of last resort and not useful for the majority of users. The first example, for BLASTP, contains general information, and should be read by all BLAST users. GenBank increases in size by thousands of sequences every week; thus, results obtained from running the same searches again will differ from those shown in the examples.

BLASTP

The BLASTP program compares a protein query to a protein database. A typical search is shown in Figure 2.5.1. The Swiss-Prot database has been selected and the program has been changed to BLASTP. A query in FASTA format has been entered in the input box. The query is the human choroideremia protein, implicated in hereditary blindness (Seabra et al., 1993).

The top of the results page for this search is shown in Figure 2.5.2. It begins with some header information about the type of program (BLASTP), the version (2.0.5), and a release

Figure 2.5.2 Example of the top portion of a BLASTP report.

BOULAY CENTRAL UNIVERSITY LIBRARY

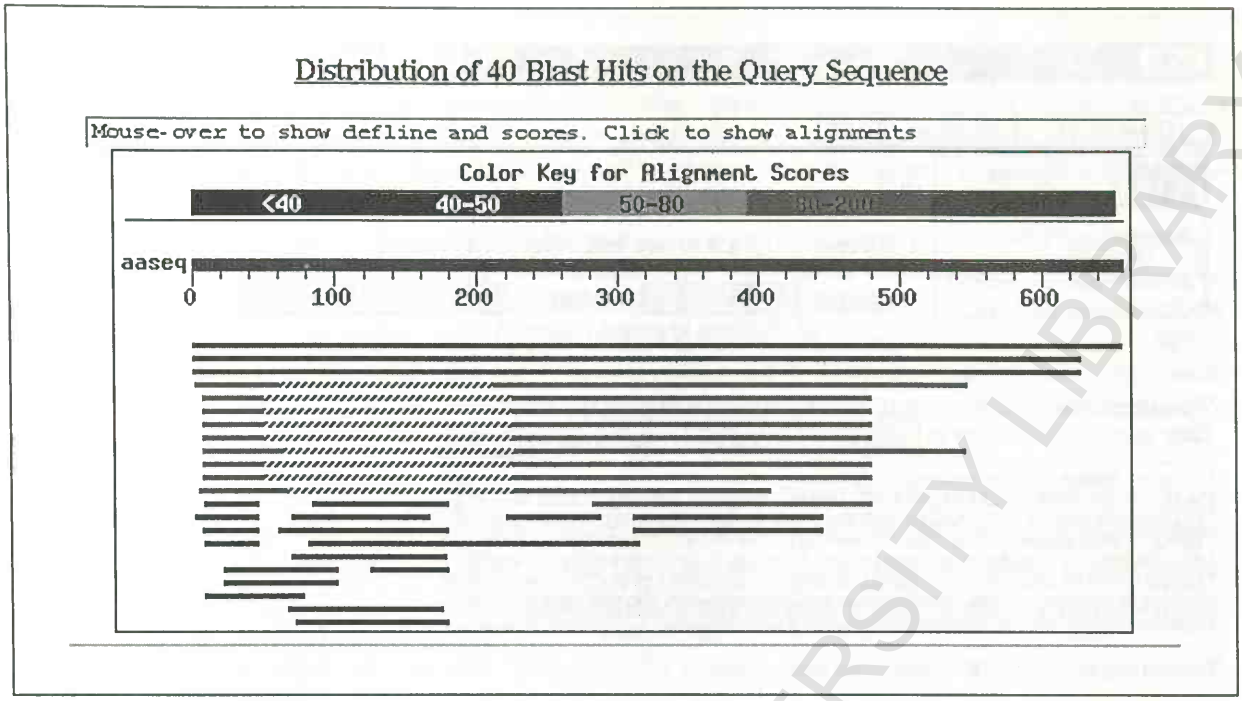

Figure 2.5.3 Example of the graphical view of a BLASTP report. The bars are color coded by the strength of the database match. The strongest matches (those with a bit score >200) are red, followed by pink (bit score 80 to 200), green (50 to 80), blue (40 to 50), and black (<40).

date. The version and release date will change as the program is updated. Also listed are a reference, the query definition line, and a summary of the database used. Figure 2.5.3 presents a graphical overview of the results. The database hits are shown aligned to the query, which is the numbered bar at the top. The next three bars show high-scoring database matches that align to the query sequence throughout its length. The next nine bars show lower-scoring matches that align to two regions of the query—one from residue 3 or 4 of the query up to about residue 60, and the other from about residues 220 to 500. For these nine bars the solid segments (on the left and right) indicate aligned regions; the cross-hatched segment indicates that the two alignments (i.e., the solid portions) are from the same database sequence, but that there is no alignment where the bar is cross-hatched. If there is no cross-hatching between two or more bars in the same row (i.e., the thirteenth row), this denotes different alignments with unrelated database sequences. These bars are presented on the same line to conserve space in the graphical view. Moving the cursor over a bar in the graphic ("mousing over") causes the identifier and definition line of the database match to be shown in the window. If the results of a BLAST search are sent by e-mail, this graphical view is not included.

The hit list produced by the BLASTP search is shown in Figure 2.5.4. Each line of the hit list is composed of four fields. The first field contains the database designation, accession number, and locus name for the matched sequence, separated by vertical bars (see Appendix B at the end of this unit for more information). The second field contains a brief textual description of the sequence, the definition line. The content of the definition line varies between and within databases, but usually includes information on the organism from which the sequence was derived, the type of sequence (e.g., mRNA or DNA), and some information about function or phenotype. The definition line is often truncated in the hit list to keep the display compact, but is fully displayed in association with the local alignments (see below). The third field contains the alignment score in bits. Higher scoring hits are found at the top of the list. In very general terms, this score is calculated from a formula that takes into account the alignment of similar or identical

Figure 2.5.4 Example of the hit list from a BLASTP report.

residues, as well as any gaps that must be introduced in order to align the sequences. A key element in this calculation is the "substitution matrix," which assigns a score for aligning any possible pair of residues. The BLOSUM-62 matrix is the default for BLAST, and it works well for most searches. The fourth field contains the Expect (*E*) value, which provides an estimate of statistical significance. *E* values reflect how many times one expects to see such a score occur by chance. A statistician would consider an *E* value <0.05 to be significant. However, an inspection of the alignments (see below) is required to determine biological significance. The maximum number of hits displayed in the hit list is set at a default value of 500. This number can be changed on the advanced BLAST page with the *descriptions* option.

For the first hit in the list, the database designation is sp (for Swiss-Prot), the accession number is P26374, the locus name is RAE2_HUMAN, the definition line begins RAB PROTEINS, the score is 1223, and the *E* value is 0.0.

The higher the score and the lower the *E* value, the more statistically significant is the hit. Note that the first thirteen hits all have very low *E* values ($<10^{-14}$) and are either RAB proteins or GDP dissociation inhibitors. The next eighteen database matches have much higher *E* values (≥0.35), meaning that roughly one match with that score would be expected by chance. Furthermore, the definition lines no longer show the same consistency. Given the combination of inconsistent definition lines and high *E* values, caution should be used in assuming an evolutionary relationship between the query and the eighteen lower-scoring database hits. It would be necessary to examine the alignments in order to make a final determination.

The pairwise alignments between the query and the database hits are displayed below the hit list. Figure 2.5.5 shows one sequence alignment between the query sequence and a

Figure 2.5.5 Example of a BLASTP alignment.

database hit; other alignments are omitted for brevity. The alignment is preceded by the sequence identifier, the full definition line, and the length, in amino acids, of the database sequence. Next comes the score of the match in bits (the raw score is in parentheses), the Expect value (*E* value) of the hit, the number of identical residues in the alignment (identities), the number of conservative substitutions (positives) according to the scoring system (e.g., BLOSUM-62), and, if applicable, the number of gaps in the alignment. Finally the actual alignment is shown, with the query on top and the database match labeled as subject (Sbjct). Since both the query and the match are amino acid sequences, the numbers at left and right refer to the position in the amino acid sequence. The center line between the two sequences indicates the similarities between the sequences. If the residue is identical between the query and the subject, the residue itself is shown; conservative substitutions, as judged by the substitution matrix, are indicated with a + sign. One or more dashes (–) within a sequence indicates insertions or deletions. Query residues masked for low complexity are replaced by Xs (see fourth and eleventh blocks, Fig. 2.5.5). By default, a maximum of 500 pairwise alignments are displayed. This number can be changed on the advanced BLAST page with the *alignments* option.

BOU IASTGENTRA UNIVERSITY LIBRARY

Results generated on the NCBI BLAST Web page contain text hyperlinks that assist the user in navigating around the page. Clicking on a colored bar in the graphical view (Fig. 2.5.3) moves the user to the sequence alignment (Fig. 2.5.5). The database sequence identifiers, visible both in the one-line descriptions of the database matches (Fig. 2.5.4) and in the sequence alignment (Fig. 2.5.5), link to the Entrez record that describes the sequence. Entrez may provide more information about the sequence, including links to relevant publication abstracts in PubMed. The score (to the right of the one-line description; Fig. 2.5.4) provides a link within the page to the alignment between that hit and the query.

BLASTX

BLASTX searches involve a six-frame translation of a nucleotide sequence queried against a protein database (Gish and States, 1993). Researchers most often use a BLASTX search if they have sequenced a DNA molecule and do not know the reading frame of the coding sequence, the beginning or end of the open reading frame, or the function of the encoded protein. It is also useful for analyzing preliminary sequence data containing potential sequencing or frameshift errors, such as ESTs, HTGs, or GSSs. A BLASTX search of the nr protein database can quickly highlight any similarities between all the open reading frames in a nucleotide sequence and any characterized proteins.

In the example illustrated here, the mRNA sequence encoding human ataxia telangiectasia (ATM; accession number U33841; Lavin and Shiloh, 1997) was queried against the nr protein database. The output is similar to that from BLASTP. At the top (not shown) is information about the search, including the query, database, and type of BLAST program used. Next is the graphical overview representing the alignment of the database hits to the query sequence (Fig. 2.5.6), followed by a list of the hits, including their definitions, scores, and *E* values (Fig. 2.5.7 shows the top portion of the list). Pairwise alignments between the query and hit sequences follow (selected alignments are shown in Fig. 2.5.8).

The top-scoring seven hits, which have scores >2600, are to other orthologs of the ATM gene (Fig. 2.5.7). Most of these hits align with the query sequence over its entire length (in Fig. 2.5.6, the first five bars span the entire length of the query sequence; note also the longer bars in the sixth and seventh lines). The 3′ end of the ATM mRNA (carboxy terminal end of the resulting protein translation), aligns with the catalytic domain of a number of phosphatidylinositol 3-kinases or similar proteins—such as the yeast TEL1 gene (a phosphatidylinositol kinase involved in controlling telomere length), the yeast ESR1 gene (a putative phosphatidylinositol kinase required for mitotic cell growth, DNA repair, and meiotic recombination), and the yeast TOR1 protein (a phosphatidylinositol kinase required for cell cycle progression). The alignment with these proteins starts in different places depending on the protein; one group starts around nucleotide 4700 of ATM (lines 9, 10, and 15 in Fig. 2.5.6), and other groups start around nucleotide 5800 (lines 17 to 19), 6800 (lines 7, 8, and 12 to 14), and 8000 (lines 20 to 60). Such similarities have provided insight into the role of ATM in response to DNA damage and cell cycle control (Lavin and Shiloh, 1997). The ATM gene also shares similarity with viral capsid proteins around nucleotides 2500 and 6000 (short bars on lines 6 to 14). However, these hits have low scores and high *E* values (not shown) and are not likely to be significant.

The hits to the orthologs of ATM reveal the location of the coding sequence within the query nucleotide sequence. In a BLASTX output, position in the query sequence (the top line of a pairwise alignment) is described as a nucleotide position, while the position in the database hit (the bottom line of the alignment) is described as an amino acid position (Fig. 2.5.8). For example, amino acids 1 to 3066 of the mouse ortholog of ATM, gi 1469394, align with the translation of nucleotide positions 190 through 9357 of the query

BOWLES CENTRAL UNIVERSITY LIBRARY

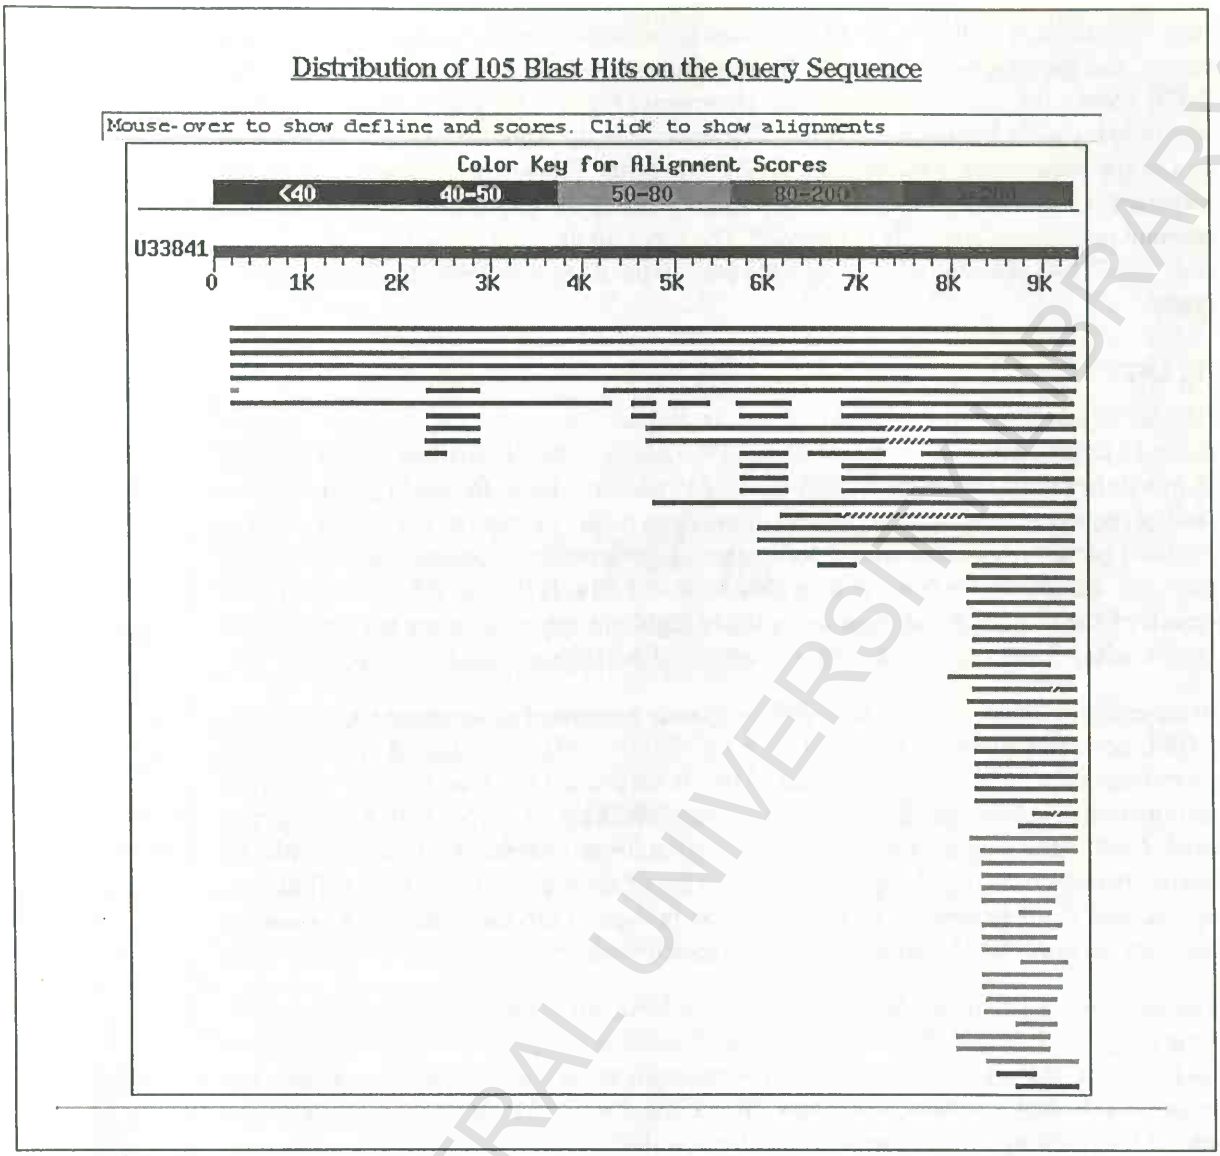

Figure 2.5.6 Example of the graphical view of a BLASTX report.

sequence. The exact location of the ATM coding sequence cannot be easily determined from the hits to the yeast sequences, as the similarity does not extend throughout the length of the protein (Fig. 2.5.8, bottom). However, the hits to the yeast sequences do provide confirmation about the phase of the reading frame, and possibly the location of specific domains conserved between humans and yeast.

TBLASTN

TBLASTN searches involve a protein sequence queried against the six-frame translation of a nucleotide sequence database. TBLASTN searches are especially useful for finding novel similarities to a protein sequence in the open reading frames from uncharacterized, sometimes lower-quality nucleotide sequences, such as those found in EST, STS, HTGS, and GSS databases. The translations of these sequences are not present in nr because the sequences are not annotated. The most common use of TBLASTN is to search for ESTs that are similar to a protein of interest. These ESTs might represent orthologs of the protein from a different species, or just additional members of a gene family.

Figure 2.5.7 Example of the hit list from a BLASTX report.

The following example shows a TBLASTN search of HTGS, a database that contains unfinished and uncharacterized genomic sequences generated by genome sequencing centers. Since HTGs are genomic and often contain introns, the results can be more difficult to interpret than those from an EST search. However, HTGs can also provide insight into the chromosomal organization of genes.

In this case, the six-frame translation of HTGS is searched with the amino acid sequence of the disintegrin-like domain of mouse ADAM 1 (Wolfsberg et al., 1995). TBLASTN output is similar to that of BLASTP and BLASTX. Figure 2.5.9 shows the graphical overview of the alignment, Figure 2.5.10 shows the list of database hits, and Figure 2.5.11

Figure 2.5.10 Example of the hit list from a TBLASTN report.

shows selected pairwise alignments between the query sequence and the hits. For TBLASTN searches, the top line (Query) of the alignment contains protein sequence, and the location refers to amino acids. The bottom line (Sbjct) of the alignment contains a translated nucleotide sequence, and the location refers to the nucleotide location.

Disintegrin-like domains contain a characteristic pattern of cysteines, so it is usually easy to identify the true hits by checking for conservation in the number of cysteine residues, and the spacing between them. The first hit, a 627-kb *C. elegans* clone, aligns with the

query sequence in two regions. Both alignments encompass the full length of the query sequence, and both contain a characteristic alignment of cysteine residues. The first region (the first aligned block) comprises nucleotides 322651-322911 of the *C. elegans* clone. The second region consists of the second and third alignment blocks. The first 55 amino acids of the disintegrin domain align with nucleotides 102880-103107 of the clone, and the last 25 amino acids align with nucleotides 103155-103232 of the clone. Thus, this *C. elegans* clone appears to encode two distinct disintegrin-like domains, and these two sequences are likely linked in the *C. elegans* genome. The region between nucleotides 103107-103155 of the clone may contain an intron. The second database hit is to a shorter *C. elegans* clone that, from the sequence of its encoded disintegrin domain, appears to contain some of the same sequence as the first *C. elegans* clone. The third database hit is to a human clone. As amino acids 1 to 16 of the query aligns with nucleotides 53178 to 53225 of the hit, and amino acids 24 to 49 align with nucleotides 53474 to 53551, the human sequence may contain an intron between nucleotides 53225 and 53474. There is a likely second intron between nucleotides 53551 and 57012.

BLASTN

Figure 2.5.12 presents the graphical overview of a BLASTN search of accession number U93237 against the human EST database. U93237 is the 9.2-kb genomic sequence of the human menin (MEN1) gene for multiple endocrine neoplasia type I. This example demonstrates the power of a BLAST search to confirm exons in a genomic sequence, as well as the danger of accepting results without further investigation. The matches on the

Figure 2.5.13 Example of the hit list from a BLASTN report.

right half of the diagram (base pairs 4000 to 9000) confirm the locations of exons 2 to 10 of the MEN1 gene (Chandrasekharappa et al., 1997; Zhang and Madden, 1997). The large number of matches on the left side of the figure (base pairs 500 to 1000 and 3000 to 3600) appear at first glance to be interesting matches, but are actually caused by the presence of *Alu* elements in the query and EST sequences. One can determine this by checking the definition lines of the matches in this region, as many of these ESTs are annotated as being similar to *Alu* elements. It is important to remember, though, that the definition line summaries (e.g., Fig. 2.5.13) contain truncated definition lines, and that it is necessary to look at the full definition line (provided in the alignment section, Fig. 2.5.14) to see the *Alu* annotation. One can also perform a BLASTN search of U93237 against the Alu database.

Fig. 2.5.13 shows the top portion of the list of database hits for the BLASTN search of U93237 against human ESTs. Fig. 2.5.14 presents one alignment of the query sequence with an EST containing an *Alu* repeat. Vertical bars connect bases that are identical in the query and subject. Since both the query and the subject are nucleotide sequences, the numbers shown refer to nucleotide sequence locations. Nucleotides in the query sequence that have been masked for low complexity are replaced by the letter n (e.g., nnnnnnn in the third block). BLASTN checks the plus and minus strand of the query against the plus strand of the database sequence. The alignment shown here presents the plus strand of the query to the minus strand of the database sequence, which is equivalent to showing the minus strand of the query against the plus strand of the database sequence.

BLASTN is optimized for speed, not sensitivity. The algorithm uses a simple system to assess the alignments; matches are given a positive score, mismatches a negative score. BLASTN should only be used when a direct comparison of nucleotide sequences is desired. BLASTN results should not be used to make any predictions about the functions of the encoded proteins. Generally, searches that involve protein comparisons are more sensitive, owing to the larger alphabet (twenty residues versus four nucleotides) and the

BCU IASTCENTRAL LIBRARY

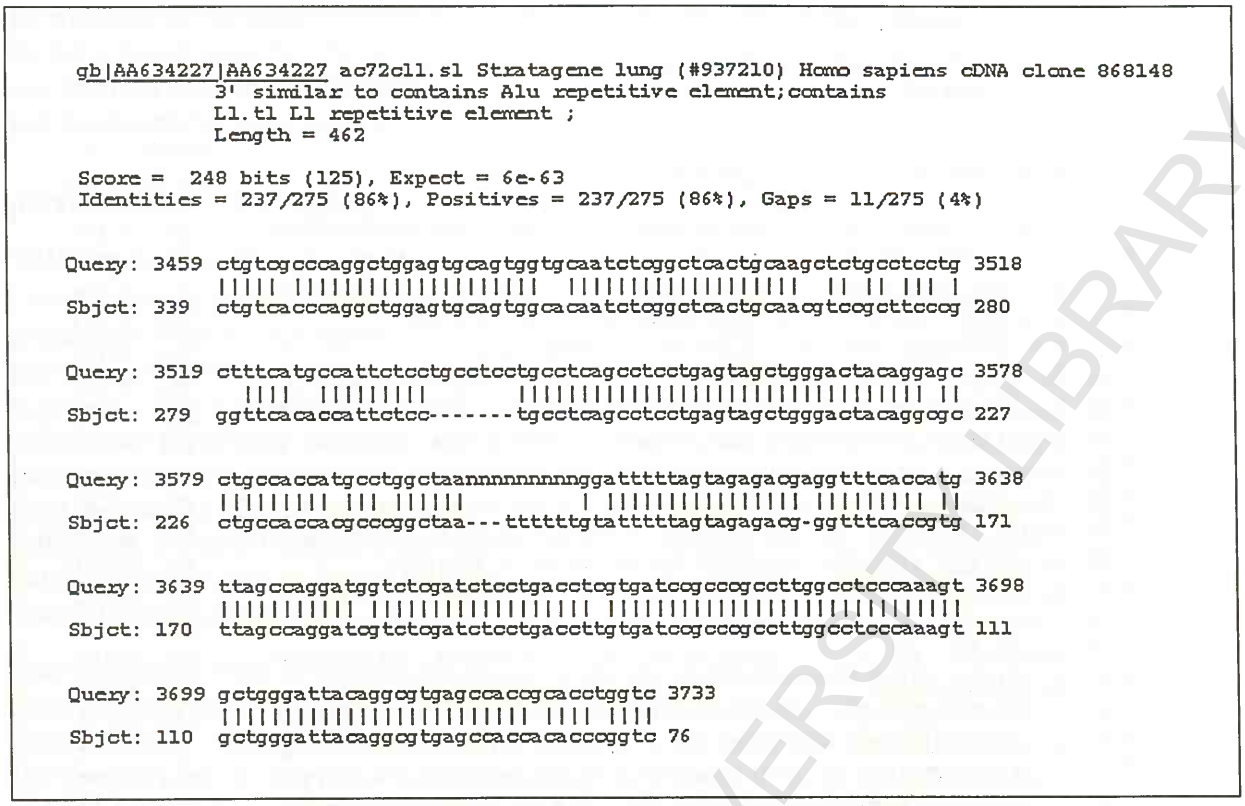

Figure 2.5.14 Example of a BLASTN alignment.

degeneracy of the genetic code (two codons, with different third bases often coding for the same protein). The more sophisticated scoring system used with protein comparisons also takes into account similarities between different residues.

PSI-BLAST

A major new feature of the BLAST version 2.0 is the iterative search. Position-specific iterated BLAST (PSI-BLAST) first performs a normal BLASTP run, but then internally computes a profile using the most significant hits (Altschul et al., 1997). A profile may be understood as a table that lists the probability of finding a residue at each position in a conserved protein domain. Conserved regions between the query and the most-significant matches are used to compute the profile. These regions are presumably important to the function of the protein. The profile is then used to perform another search (or iteration), at which point the new hits are also added into the profile. The cycle may then be repeated, with a new profile computed from the results of the last iteration. Each PSI-BLAST iteration takes into account the most significant sequences found in the previous round (i.e., those below the threshold for inclusion in the profile). The algorithm is more sensitive than BLASTP, and more likely to lead to the discovery of distantly related sequences. At present, such iterative searching is only available with the BLASTP program.

The PSI-BLAST output is different from the other programs. Figure 2.5.15 shows the one-line summaries from the first PSI-BLAST iteration (i.e., the first search using the profile) of a mouse adenosine deaminase (Swiss-Prot accession P03958) against the nr database. The one-line summaries are divided into two groups, those with an *E* value better (lower) than that used to build the profile (Fig. 2.5.15; the default value is 0.001), and those with a worse *E* value (not shown). Matches better than the threshold, which will be included in the profile, are checked. The user may check (or uncheck) matches, causing them to be included (or excluded) from the profile used in the next iteration. Matches found on a previous iteration are marked with a green ball. New sequences are

BOSTON BIOMEDICAL UNIVERSITY LIBRARY

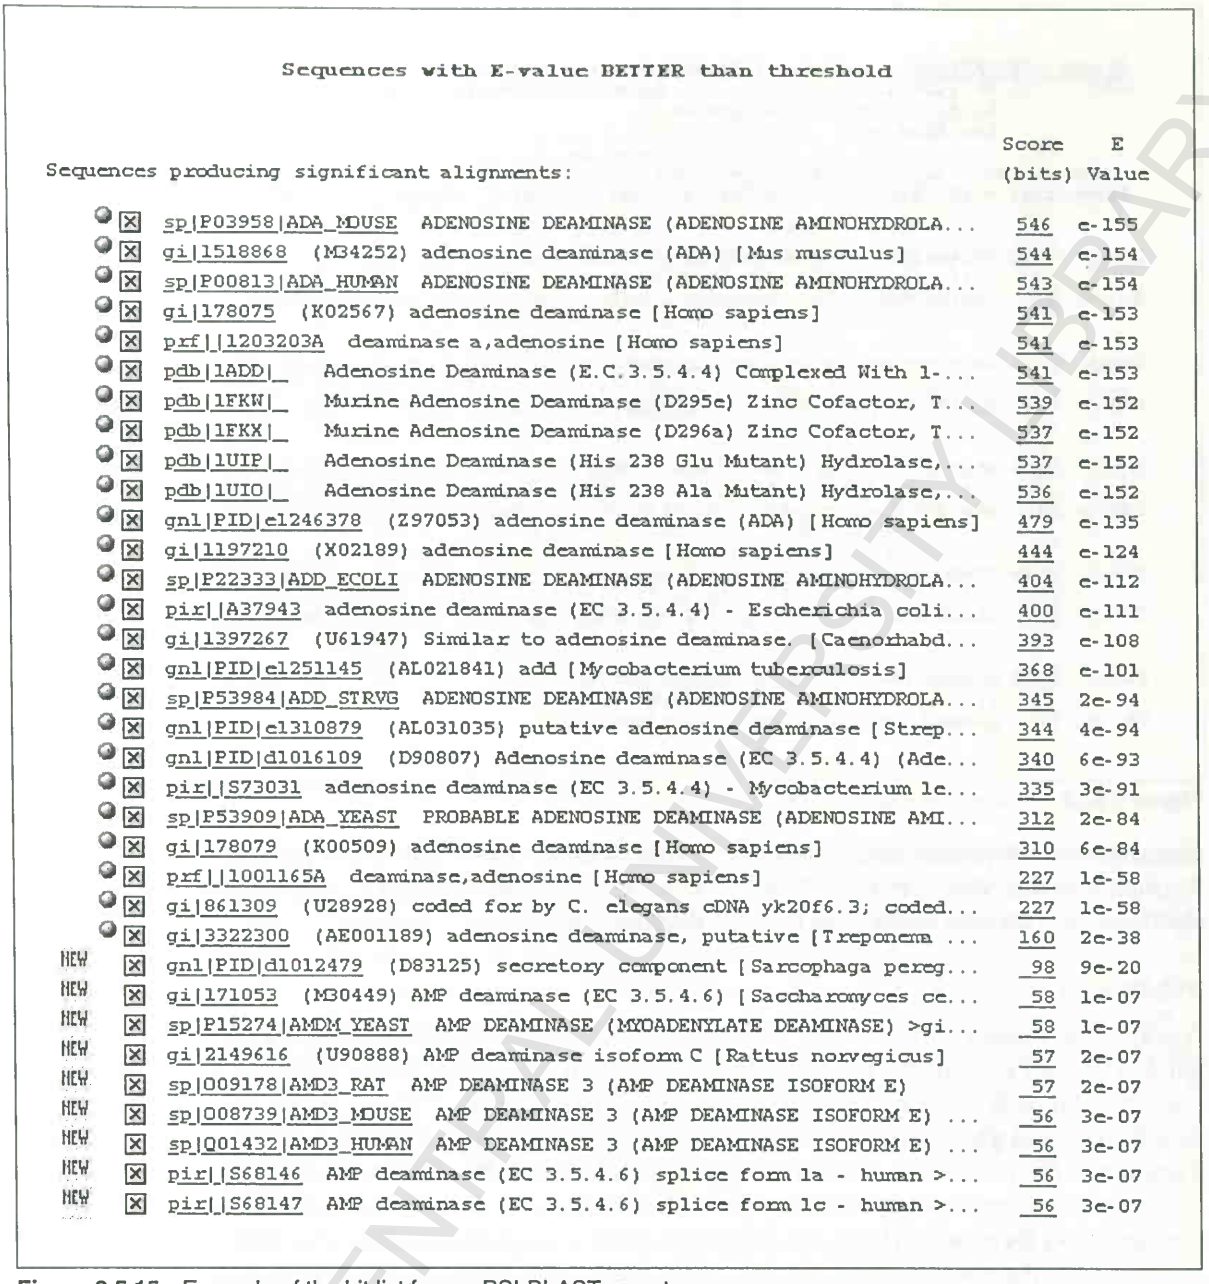

Figure 2.5.15 Example of the hit list from a PSI-BLAST report.

marked with a yellow "new". The page also alerts the user when convergence is achieved (i.e., no new sequences below the threshold for inclusion in the profile were found in that iteration).

In the hit list in Figure 2.5.15, the first iteration of PSI-BLAST finds many adenosine deaminase sequences (marked with a green ball) found in the previous (standard) BLASTP search. In addition, PSI-BLAST identifies a number of AMP deaminase sequences (marked with "new"). Indeed, there is a well-known homology between adenosine deaminase and AMP deaminase (Chang et al., 1991; Holm and Sander, 1997) that would not normally be found by BLASTP, but is found by PSI-BLAST.

If one wants to report the *E* value for a hit found with a PSI-BLAST search, one should use the *E* value calculated during the first iteration that the match is below the threshold

BCU IAS / CENTRAL UNIVERSITY LIBRARY

for inclusion in the profile (i.e., when the hit is marked with a "new" flag). However, if the hit is found in the first BLASTP run, then the reported *E* value should be from this run. In either case, in subsequent iterations, the hit itself is used to compute the profile, and the reported *E* value is not representative of the true value.

SEARCHING STRATEGIES

Filtering for Low-Complexity Regions

Low-complexity regions tend to result in misleading database search results. The residue frequencies within such regions differ dramatically from the database as a whole, disrupting the statistics used by BLAST. This can produce alignments that are based purely on compositional bias rather than a significant position-by-position alignment. By default, low-complexity sequences are filtered out of query sequences and replaced by strings of n (nucleotide) or X (protein). A BLASTP search of a proline-rich, DNA-directed RNA polymerase (Swiss-Prot accession P11414) against the nr database illustrates the differences in output resulting from a filtered or unfiltered query sequence. Twenty four database matches with an *E* value better than 10 are found if filtering is enabled; 4873 are found if filtering is disabled.

The top-scoring database matches for the unfiltered search are shown in Figure 2.5.16; high-scoring matches that are not found in a filtered search are marked. Note that the definition lines of most of the new matches indicate that the sequences are proline-rich, like the query, but do not provide information about the function of the protein. Other hits to RNA polymerases, found near the top of the list in a filtered search, are buried much deeper in the list of matches. The match to "splP14248," apparently a good match based on the definition line, does not appear in a filtered BLAST search. An examination of the alignment (not shown) indicates that the match is based on solely on proline-rich regions.

Reporting BLAST Results

The most reliable indicator of the importance of a BLAST alignment is the Expect (*E*) value (the number of chance database matches one expects to see at the same score). This number takes into account the length of the query and size of the database as well as the scoring system. Neither the bit nor the raw score is a reliable indicator, as their significance cannot be judged independently of the information used to calculate the *E* value. Normal intuition fails when one is faced with databases of the current size (e.g., the EST database contains ~700 million base pairs at this time), as chance alignments are likely and it is impossible for a user to know at what score matches become significant. Statistical significance also varies from database to database (e.g., a hit with a certain score may be statistically significant in a search of the relatively small month database, but not in a search of nr), so that reporting a certain score without the context of the database size can be misleading. The percentage identity is also a poor indicator of statistical significance for the same reasons; additionally, there is really no way to estimate an *E* value or even a score from a percentage identity, making it impossible to even guess whether a hit could be due to chance or not.

Analyzing mRNA Sequences

1. Identify the open reading frame to obtain the protein sequence. Perform a BLASTX search of the cDNA sequence against the nr protein database. Any resulting hits may identify the correct reading frame for the protein sequence and provide information about its function.

Figure 2.5.16 Example of a hit list from a BLASTP report in which the query sequence was not filtered. Black squares, added manually by the authors, indicate hits that would not appear if the query had been filtered.

2. Determine whether the protein sequence is similar to that of any previously identified proteins. Perform a BLASTP and a PSI-BLAST (iterative) search against the nr protein database using the protein sequence as a query.

3. Determine whether the protein sequence is similar to the translation products of any uncharacterized DNA sequences whose translations are not in nr. Perform a TBLASTN search of the EST, STS, GSS, and HTGS databases.

4. After the initial search, perform a monthly search of the month nucleotide and protein sequence databases to provide information about newly added sequences. A BLASTP

BU IASI / CENTRAL UNIVERSITY LIBRARY

search of the month protein database will reveal newly characterized protein sequences. A TBLASTN search of the month nucleotide database will reveal new open reading frames in nr, EST, HTGS, STS, and GSS. PSI-BLAST searches of nr should also be conducted occasionally, as new sequences may be added to the profile that will, in turn, help identify more distantly related sequences.

5. If the protein sequence contains multiple functional domains, it may be useful to perform the searches with each of these domains individually.

Analyzing Genomic DNA Sequences

1. Identify a potential transcribed segment. Perform a BLASTN search of the nucleotide sequence against the DNA sequences in the EST database to determine if any mRNAs are derived from the genomic sequence. EST hits will highlight the location of exons. A BLASTN search against nr may identify transcripts or previously characterized genomic segments.
2. Identify potential open reading frames. Perform a BLASTX search against the nr protein database. Any resulting hits may identify the correct reading frame of a protein sequence and provide information about its function. If no results are found with the previous methods, a TBLASTX search (translated nucleotide query versus a translated nucleotide database) against EST, GSS, HTGS, and STS may identify other open reading frames.
3. After the initial search, a monthly search of the month nucleotide (with BLASTN) and protein (with BLASTX) sequence databases will provide information about newly added sequences.
4. Any potential transcribed sequences can be analyzed as per the above instructions for mRNA sequences.

Searching Short Sequences

Short sequences can only produce short alignments. Such short alignments need to be relatively strong (i.e., have a high percentage of matching residues) to rise above the background noise. Short, but strong, alignments are more easily detected using a matrix with a higher relative entropy than that of the default BLOSUM-62 (Altschul, 1991). Relative entropy is basically the average information available per position to distinguish the alignment from chance. The BLOSUM series of matrices does not include any that are suitable for the shortest queries, so it is recommended to use the PAM matrices instead (Dayhoff et al., 1978; Schwartz and Dayhoff, 1978). These matrices may be chosen from a menu on the Advanced BLAST page. Suggested matrices for different query lengths are shown in Table 2.5.2 (S.F. Altschul, pers. comm.).

Table 2.5.2 Substitution Matrices for Short Sequences

Query length (amino acids)	Matrix
<35	PAM-30
35-50	PAM-70
50-85	BLOSUM-80
>85	BLOSUM-62

BCU IASL / CENTRAL UNIVERSITY LIBRARY

SEQUENCE ALIGNMENT ALGORITHMS

There are two types of pairwise sequence alignments, global and local. Global strategies attempt to align along the entire length of both sequences, while local alignments focus on sequence similarity over shorter regions. Historically, local alignments have been very successful at identifying similarities between proteins. Subsequences of similarity, surrounded by unrelated sequences, can identify, for example, active sites that are conserved between proteins or exons in genomic sequence. Smith and Waterman (1981) were the first to develop a local alignment algorithm. However, such rigorous alignment algorithms are often quite slow and impractical for searching current databases on a routine basis.

Heuristic algorithms implement certain shortcuts to allow a comparison against an entire database within a reasonable time. They are not exhaustive searches in the sense that they do not explore possibilities that seem unlikely to be interesting. Some programs allow the user to adjust parameters that increase the sensitivity of the search (i.e., explore more possibilities), but this must be balanced against the slower speed of the search. Studies have shown that heuristic algorithms, with default settings, approach the sensitivity of exhaustive searches (Altschul et al., 1997). BLAST (Altschul et al., 1990, 1997) and FASTA (Pearson, 1990; Pearson and Lipman, 1988) are two popular heuristic programs. The rest of this discussion will focus on the newest version (2.0) of BLAST.

BLAST calculates a statistical significance for every alignment it produces. Significance is expressed in terms of the *E* value, which is the number of matches with a given score (the calculation of the score is described below) that one would expect by chance. The *E* value depends on the size of the database and the length of the query, as increasing either of these parameters increases the number of chance matches. Calculation of the *E* value is performed with Karlin-Altschul statistics (Karlin and Altschul, 1990, 1993).

The raw score of an alignment is calculated with a scoring system, which is a table of residue substitution scores and penalties for the existence and extension of a gap. For normal protein/protein comparisons, a matrix (i.e., table of residue substitution scores) provides a score for each possible alignment of two amino acids. For example, L aligned with I gets a positive score, while L aligned with E gets a negative score. BLOSUM-62 is the default matrix, and experimentation has shown that it is among the best for detecting weak protein similarities (Henikoff and Henikoff, 1992). PSI-BLAST uses a table that lists the frequency of finding a certain residue at each position in a conserved protein domain. This table is calculated "on the fly" for each iteration from the best matches to the database. BLASTN uses a simple scheme where matches have a positive score and mismatches have a negative score. Gaps are opened or extended when one sequence is longer than another over a certain region. BLAST charges the score $-a$ for the existence of a gap and $-b$ for each letter in a gap, so that a gap of length k letters is penalized $-(a + bk)$. Gap costs of this form are known as affine gap costs. These gap costs may be changed by the user.

The scoring system determines the raw score of an alignment. A bit score can be calculated from the raw score using the following formula:

$$S_{bit} = [\lambda \times S_{raw} - \ln(K)]/\ln(2)$$

where λ and K are Karlin-Altschul parameters that depend on the scoring system. The statistical significance corresponding to the resulting bit score is independent of the scoring system used. This allows one to compare the bit scores obtained from two different BLAST runs, each performed using different matrices or gap extension and existence values. Nevertheless, it is more meaningful to compare the results of different BLAST

BCU IAS / SETTLE LIBRARY UNIVERSITY

runs using their *E* values rather than their bit scores, as the *E* value takes into account the size of the database.

A word-based approach is used to find matches in BLAST. An ungapped search, with BLASTN, may be used to demonstrate the concept of a word. First a list is made of all the subsequences in the nucleic acid query sequence that are of a certain length (called the word size), and the positions are recorded. The database is then scanned, looking for words that are in the list. If a match is found between a query and a database word, the alignment is extended (without allowing gaps) until the corresponding score drops a certain amount below the maximum found, at which point that maximum score (and the corresponding alignment) is used. The aligned region is a local alignment. With BLASTN, only exact matches are extended and the default word size is 11 bp.

The procedure is more complicated for the other programs (BLASTP, BLASTX, TBLASTN, and TBLASTX). Exact word matches are not required and the default word size is three residues. A match between a query word and a database word is based on the scoring matrix, which specifies whether two residues result in a positive, negative, or neutral match. If three residues in a query word are compared with three residues in a database sequence, and the score is above a certain threshold, this word warrants further consideration. The default behavior in BLAST version 2.0 is that two words (on the query) must match with two words (on the database sequence) within a window of 40 residues before the match is extended, as described for BLASTN. The effect of looking for two word matches is to eliminate random matches, increasing the speed of BLAST by a factor of three.

Ungapped alignments are used as a starting point for the gapped alignments that BLAST produces. The eleven highest-scoring letters are determined and the center letter is used as the start of the gapped alignment. The alignment is then extended, with gaps allowed. This extension is not exhaustive; if the score drops by more than a certain amount from the maximum found so far, that maximum (and the corresponding alignment) is used (Altschul et al., 1997; Zhang et al., 1998).

The default BLAST parameters are tuned for a balance of speed and sensitivity. It is possible that significant matches may be missed, especially if small databases are searched. In that case, it may be advisable to use a shorter word size for BLASTN or a lower-threshold word for the other programs.

It is important to remember that BLAST calculates similarity. Homology is an evolutionary relationship that must be proved by further analysis.

APPENDIX A: BLAST PARAMETERS

The Advanced BLAST page offers the possibility to change a number of BLAST parameters. The most important options supported are listed below.

Descriptions (pull-down menu) restricts the number of one-line descriptions to the number specified. The default is 500.

Alignments (pull-down menu) restricts the number of database hits for which alignments are shown. Several alignments may be associated with one database sequence, so the number of alignments may actually be larger than this number. The default is 500.

Expect value (pull-down menu; also known as the *E* value) is the statistical significance threshold for reporting matches. The default value is 10, such that ten alignments are expected to be found merely by chance, according to the stochastic model of Karlin and Altschul (1990). Lower *E* thresholds are more stringent, leading to fewer chance matches being reported. Fractional values are acceptable.

Filtering (pull-down menu) masks off segments of the query sequence that have low compositional complexity, as determined by the SEG program (Wootton and Federhen, 1993, 1996) or, for BLASTN, by the DUST program (R.L. Tatusov and D.J. Lipman, pers. comm.). Filtering is only applied to the query sequence (or its translation products), not to database sequences. Default filtering is DUST for BLASTN, SEG for other programs.

Genetic code (pull-down menu) selects the genetic code to be used for a BLASTX translation of the query. The default setting is the universal code. The choice of code is determined by the source of the query sequence (e.g., species, mitochondrial).

Graphical overview (checkbox) selects whether an overview of the database sequences aligned to the query sequence will be shown. The score of an alignment is indicated by one of five different colors, which divides the range of scores into five groups. If more than one alignment is displayed for a database sequence, the two alignments are connected by a cross-hatched bar. Mousing over a match causes the definition and score to be shown in the window at the top; clicking on a bar takes the user to the associated alignments. The overview is on by default.

Matrix (menu) allows one to change the matrix from the default of BLOSUM-62. This is useful for searches against short sequences (see Searching Short Sequences). It is also possible to change the gap existence and extension penalties, but the defaults for a given matrix are recommended.

Organism (pull-down menu) limits the search by organism. The menu provides a list of the most common organisms; others may be entered in a text box.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

APPENDIX B: SEQUENCE IDENTIFIER SYNTAX

The syntax of sequence header lines used by the NCBI BLAST server depends on the database from which each sequence was obtained. Table 2.5.3 lists the identifiers for the databases from which the sequences were derived. For example, an identifier might be *gb|M73307|AGMA13GT*, where the gb tag indicates that the identifier refers to a GenBank sequence, M73307 is its GenBank accession number, and AGMA13GT is its GenBank locus.

NCBI assigns gi identifiers for all sequences contained within NCBI's sequence databases (Ostell and Kans, 1998). The gi identifier provides a uniform and stable naming convention whereby a specific sequence is assigned its unique gi identifier. If a nucleotide or protein sequence changes, a new gi identifier is assigned, even if the accession number of the record remains unchanged. Thus, gi identifiers provide a mechanism for identifying the exact sequence that was used or retrieved in a given search.

For searches of the nr protein database where the sequences are derived from conceptual translations of sequences from the nucleotide databases the gi syntax is *gi|gi_identifier*. An example would be *gi|451623 (U04987) env [Simian immunodeficiency...*, where 451623 is the gi identifier and U04987 is the accession number of the nucleotide sequence from which it was derived.

Users may select the *-gi* option for BLAST output, which will produce a header line with the gi identifier concatenated with the database identifier of the database from which it was derived. For example, *gi|176485|gb|M73307|AGMA13GT* would be used for a match from a nucleotide database, and *gi|129295|sp|P01013|OVAX_CHICK* for a protein database.

The gnl (general) identifier allows databases not listed in Table 2.5.3 to be identified with the same syntax. An example here is the PID identifier *gnl|PID|e1632*. PID stands for Protein-ID, and the e in e1632 indicates that this ID was issued by EMBL. As mentioned above, use of the *-gi* option produces the NCBI gi (in addition to the PID), which users can also use to retrieve sequences of interest.

Table 2.5.3 Identifier Syntax for Sequence Databases

Database	Identifier syntax

Ion-Exchange Chromatography

Ion-exchange chromatography separates biomolecules on the basis of charge characteristics. Charged groups on the surface of a protein interact with oppositely charged groups immobilized on the ion-exchange medium. As illustrated in Figure 8.2.1, the charge of a protein depends on the pH of its environment (the operating pH). The pH at which the net charge of a protein is zero (i.e., where the number of positive charges equals the number of negative charges) is known as the isoelectric point (pI). When the operating pH is greater than the pI, the protein will have a net negative charge, and should bind to anion-exchange media, which are positively charged. When the operating pH is less than the pI, the protein will have a net positive charge, and should bind to cation-exchange media, which are negatively charged.

The Strategic Planning section outlines the basic steps in planning and carrying out ion-exchange chromatography to separate proteins. Basic Protocol 1 describes batch adsorption of protein to an ion-exchange medium followed by elution using a step gradient of increasing salt concentration. This technique accommodates a wide range of sample volumes and is most often used in the initial capture stage of protein purification (*UNIT 8.1*). Batch techniques have minimal system requirements. The Alternate Protocol describes use of a buffer of a different pH to elute via step gradient. Basic Protocol 2 describes adsorption of protein to an ion-exchange medium in a column, followed by elution with a linear gradient. Basic Protocol 2 provides a higher resolution than Basic Protocol 1, and is therefore used in the intermediate purification and final polishing stages of protein separation (*UNIT 8.1*). Support Protocol 1 describes a pilot experiment to determine initial conditions for batch or column chromatography (i.e., pH required for binding, change in pH or salt concentration required for elution, and available capacity of a medium). Support Protocol 2 describes a means of calculating the dynamic capacity (*UNIT 8.1*) of an ion-exchange column, Support Protocol 3 describes methods for producing continuous gradients of pH and salt concentration to elute proteins from ion-exchange

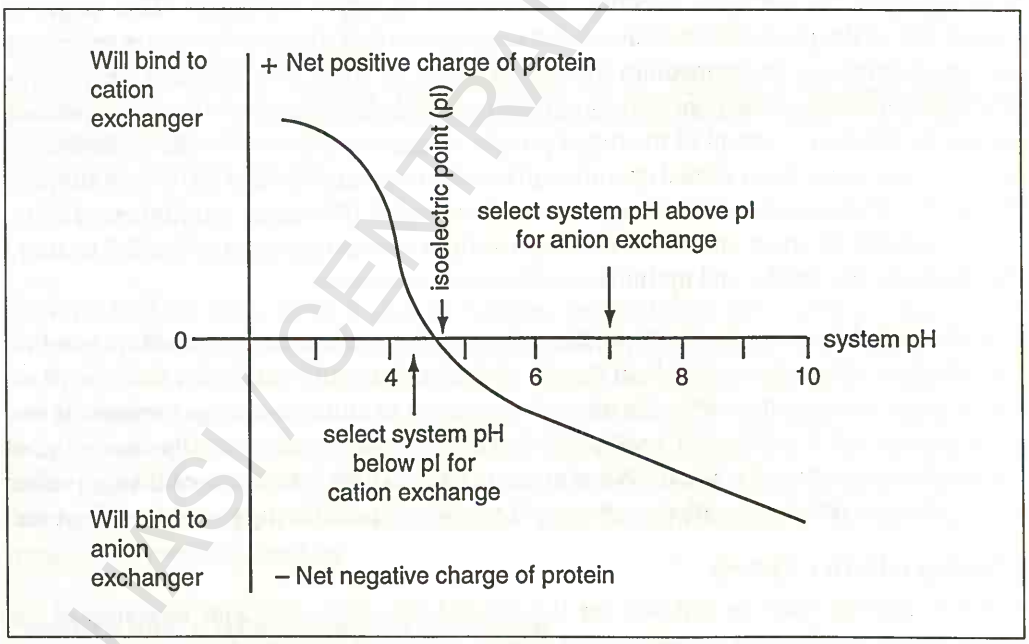

Figure 8.2.1 Net charge of a protein as a function of pH, showing the pH ranges in which protein is bound to anion or cation exchangers. The pH range over which the protein is stable may be only a small fraction of the binding range; this must also be taken into consideration when choosing an ion-exchange medium.

columns, Support Protocol 4 describes regeneration of used ion-exchange media, and Support Protocol 5 details storage of ion-exchange media.

STRATEGIC PLANNING

There are a number of basic steps in developing an ion-exchange method for protein purification. First, an appropriate ion-exchange medium must be selected, as well as the optimal operating pH and buffer system for the medium and sample (see following discussions on Selecting an Ion-Exchange Medium and Selecting a Buffer System). It is then necessary to decide whether batch or column chromatography is appropriate given the purity, protein concentration, and physical characteristics of the sample, the sample volume to be used, and the availability of suitable equipment (see following discussion on Selecting Batch Versus Column Purification). Next, pilot experiments are conducted to determine conditions for binding and eluting the protein (see Support Protocol 1). It is also necessary to make sure that the capacity of the medium is sufficient to isolate the desired quantity of protein (see Support Protocol 1 and Support Protocol 2). When these initial conditions have been determined, the medium and sample are prepared, the sample is bound to the medium, unbound sample components are washed away, and bound sample components are selectively eluted and collected (see Basic Protocol 1, Basic Protocol 2, or Alternate Protocol). The medium may then be cleaned and regenerated (see Support Protocol 5). Finally, results are evaluated and conditions optimized if necessary (see Critical Parameters).

Selecting an Ion-Exchange Medium

A wide variety of ion-exchange media are commercially available, but no miracle medium exists that is best for every protein purification. Criteria for selecting an ion-exchange medium include the specific requirements of the application, the pI and molecular size of the sample components (i.e., target protein and contaminants), and the available equipment (e.g., pumps and columns).

It is necessary to begin by selecting either anion or cation exchange. This requires knowledge of the pI and pH stability of the target protein. If the pI of the target protein is known, an anion-exchange medium with an operating pH above the pI of the target protein or a cation-exchange medium with an operating pH below the pI of the target protein should be selected. If the pI of the target protein is unknown, it is desirable to determine it before beginning. The optimal operating pH can be determined empirically (see Support Protocol 1). Because the pI for most proteins is below pH 7 (Gianazza and Righetti, 1980), it is reasonable to select an anion-exchange medium and an operating pH of 8.5 to start, then evaluate the results and optimize conditions as necessary.

It is also useful to know the pI and binding characteristics of the contaminants present in the protein solution. For example, if the pH of the binding buffer is higher than the pI of a major contaminant, that contaminant will not bind to an anion-exchange medium. If the starting material is crude cell lysate, DNA will be present and generally needs to be removed from the protein. Since DNA is anionic, it binds tightly to anion-exchange media and typically is not eluted with the salt and pH conditions used during protein purification.

Selecting a Buffer System

A buffer system must be selected for the desired pH range. As with selection of an ion-exchange medium, there are several factors that must be considered in selecting a buffer system, including the type of ion exchange to be performed, the pH stability of the sample and the pH range to be used, the required buffering capacity, and, finally, the cost.

[c]Change in pK_a per °C (i.e., $\partial pK_a/\partial T$).

Anionic buffers (e.g., acetate and phosphate) are preferred for cation exchange and cationic buffers (e.g., Tris·Cl, ethanolamine, and piperazine) are preferred for anion exchange. It is important to ensure that the buffering ion will have the same charge as the ion exchanger, and hence will not be bound. A constant buffering capacity and pH will thus be maintained during the ion-exchange experiment. Table 8.2.1 lists a variety of buffers useful for anion and cation exchange. Additives to be included in the buffers (e.g., detergents or protease inhibitors) should also carry the same charge as the ion-exchange medium, to preclude binding.

Selecting Batch Versus Column Purification

If the sample volume is large in relation to the size of the pumps and columns available in the laboratory, batch adsorption techniques (see Basic Protocol 1) are appropriate for the capture stage of purification. Batch methods, in which the sample and medium are directly mixed without use of a column, are employed to reduce the sample volume and

total protein content prior to column chromatography. Batch techniques are also very useful for capture of the target protein from extremely crude samples (e.g., cell lysates and samples containing particulates and/or aggregates). In batch methods the flow and packing characteristics of the medium are of minor importance, but economy and capacity are of primary importance. Ion-exchange media suitable for batch purification at the capture stage of protein purification are presented in Table 8.2.2.

High resolution is required in the intermediate purification and polishing stages of protein purification, and this can only be achieved using column chromatography. However, higher-than-necessary resolution is frequently traded off for greater throughput (i.e., amount of material processed in a defined time). The packing and flow characteristics of the medium are of primary importance when using column chromatography. Columns packed with smaller beads usually require higher operating pressures than columns packed with larger beads. However, smaller beads offer higher resolution, resulting from the increased efficiency that comes with decreasing bead size. Larger beads are desirable for applications requiring higher throughput. A medium with the smallest bead size that will provide the necessary throughput (and whose operating pressure can be accommodated by available equipment) should be selected. Table 8.2.3 lists a variety of media suitable for column purification at various stages in the purification process. See *SUPPLIERS APPENDIX* for contact information of suppliers of these media, all of whom provide technical support for selection and use of specific media.

Capacity of Ion-Exchange Media

The amount of ion-exchange medium required for a particular application will be determined by the protein capacity of the medium (i.e., the amount of protein that can be bound to the matrix) at the chosen pH. The amount of medium required will in turn determine the size of column required. The capacity of an ion-exchange medium is dependent on a variety of factors, including charge and molecular size of the components in the sample and experimental conditions employed.

The number of charged groups on a specified amount of matrix that can participate in ion exchange is termed **ionic** or **total** capacity. However, ion-exchange media are porous and the ion-exchange groups are usually distributed throughout the bead. The amount of protein that will bind is dependent on the ability of the sample components to diffuse into the bead, and this ability is related to the molecular weight and shape of the components and the pore structure of the matrix (see *UNIT 8.3*). In addition, large molecules such as proteins and nucleic acids can bind to multiple ion-exchange groups (or sterically hinder other molecules from binding) depending on the shape and surface-charge distribution of the protein, as well as the spatial orientation of the exchange ligands on the matrix. These factors are taken into account in the available and dynamic capacity of a matrix or column.

Available capacity is defined as the amount of a specific protein that will bind to an ion-exchange medium at a defined pH, salt concentration, and sample concentration in a batch purification process. When medium is packed in a column, the amount of a specific protein that will bind is dependent on many of these factors, as well as on the column dimensions and flow rate. The capacity of a column operating under defined conditions is termed the **dynamic capacity**. The dynamic capacity is typically less than the available capacity for the same sample under the same operating conditions.

Ion-exchange media in which the charge state of the ligand is sensitive to the operating pH are termed weak ion exchangers. The usable pH range of weak ion exchangers is narrower than that of strong ion-exchange media, in which the charge on the ligand used for exchange is constant (i.e., insensitive to pH). Ion-exchange media with DEAE (diethylaminoethyl) or CM (carboxymethyl) groups as the ligand for exchange are considered weak ion exchangers. Because the ionic capacity of weak ion-exchange media is variable, strong ion-exchange media are recommended for pilot experiments (see Support Protocol 1).

When selecting ion-exchange media for batch or column purifications, the amount of medium should be estimated from the manufacturer-supplied capacity data for a protein similar in size to the target protein to be purified. Be aware of what type of capacity (i.e., ionic, available, or dynamic) is being reported and the experimental conditions under which the reported capacity was determined (see Table 8.2.3). A general recommendation is to begin pilot experiments at ~10% of the published capacity data, then determine the capacity for your system.

Preparing Solutions

All aqueous solutions for use in ion-exchange chromatography should be prepared with distilled or deionized water (Milli-Q purified or equivalent). Solutions and samples for column chromatography should be filtered, degassed, and equilibrated to the appropriate temperature prior to use. Special attention must be given to any additives to be included in the buffer to be sure that they will not bind to the column (see preceding discussion on Selecting a Buffer System). If the chosen additives increase the viscosity of the mobile phase, the flow rate should be decreased.

Chromatography Systems

Column techniques typically result in higher resolution than batch techniques, and should be used during the intermediate purification and polishing stages (*UNIT 8.1*) of a purification procedure. However, to achieve high resolution, an appropriate chromatography system is required. A chromatography system may be described simply by the functional operations required to perform a chromatographic separation. The minimum functions required (Fig. 8.2.2) include a buffer delivery system capable of gradient formation, a mechanism for introducing sample into the system, the column itself (properly packed with the appro-

RCU IAS LIBRARY

Gradient volume (ml)	20	200	2000

[a]Linear flow (cm/hr) multipled by the cross-sectional area of the column (cm^2) equals the volumetric flow rate (ml/hr); cm/hr × cm^2 = cm^3/hr = ml/hr.

priate ion exchanger), an in-line UV monitor suitable for use at 280 nm, a chart recorder, and a fraction collector to preserve the separation. Additional unit operations may include system controllers for automated operation as well as data-acquisition systems. The equipment required to perform each of these unit operations is ultimately determined by the chromatography medium and column selected. Specifically, the operating pressure and flow characteristics of the packed column will be the most important factors for selecting equipment to fit the column, or for selecting columns to fit existing equipment.

It is highly recommended that prepacked columns be used and that the manufacturer be consulted prior to purchase as to equipment requirements for proper operation. This will save time and money and increase the probability of success. If columns are to be packed in the laboratory, the manufacturer's packing instructions for the medium should be followed and column efficiency and function should be tested with representative standards prior to use with the actual sample. There is no single packing methodology that is optimal for all types of media. Table 8.2.3 lists a variety of ion-exchange media available in prepacked columns and/or in bulk for packing in the laboratory. Several manufacturers offer inexpensive disposable ion-exchange columns, suitable for many applications, that can be operated using only a syringe.

Scale-Up Conditions

Ion-exchange separations are typically developed and optimized on a small scale before the entire sample is committed. It is thus important to choose an ion exchanger that will allow simple and convenient scale-up, so that methods established on a small column can be applied more or less directly to a larger one.

Scaling up in ion-exchange chromatography can be approached in two different ways—either the same ion-exchange medium can be used in a larger-diameter column with the same bed height, or a different medium having the same charged group immobilized on a matrix with a higher throughput can be substituted for the medium used in the small-scale separation.

B. C. U. „M. EMINESCU" IAŞI
CHIMIE

The former approach, using the same medium throughout, is the simplest. Scaling up a separation with the same medium and bed height used in the small-scale optimization is achieved by employing simple scale factors to adapt the flow, gradient volume, and sample load to the increased volume of a larger-diameter column. The scale factor for the required increase in flow rate is the ratio of the cross-sectional area of the larger column to that of the smaller column (i.e., the factor by which the total flow of solution through the column must be increased so that the same linear velocity used in the small-scale experiment is maintained). The increase in gradient volume and sample loading are directly proportional to the increase in column volume. Table 8.2.4 shows an example of changes that must be made to various parameters for a 10- and 100-fold increase in scale.

BASIC PROTOCOL 1

BATCH ADSORPTION AND STEP-GRADIENT ELUTION WITH INCREASING SALT CONCENTRATION

This protocol describes adsorption of a protein to an ion-exchange medium by direct mixing of the protein-containing sample and the medium (in this case, an anion-exchange gel). This batch purification is in contrast to column purification (see Basic Protocol 2), in which the gel is packed in a column and the sample is passed through it. Batch adsorption is particularly useful where large volumes of sample are involved, which is usually the case in the capture stage of protein purification (*UNIT 8.1*). The equipment used here is sufficient for sample volumes up to 1.5 liter. Larger samples may be divided and processed with parallel apparatuses, or processed sequentially on a single apparatus. Different-sized funnels and side-arm flasks may be used when appropriate.

Once the starting conditions have been determined (see Support Protocol 1), the range of pH and salt concentration where binding and elution occur is well defined. Conditions for batch adsorption and elution used in this procedure are based on the results, presented in Figure 8.2.3, of a test tube pilot experiment performed as described in Support Protocol 1. Buffer volumes and equipment were chosen on the basis of a sample volume of 1 liter containing 50 to 1000 mg of total protein.

Elution of sample components adsorbed to an ion-exchange medium can be achieved either by increasing the salt concentration of the mobile phase, as in this protocol, or by changing its pH (see Alternate Protocol). In batch techniques, discontinuous (step) gradients are used for elution. Column chromatography (see Basic Protocol 2) allows the use of either step or continuous gradients. Formation of continuous gradients requires special equipment (see Basic Protocol 2 and Support Protocol 3).

The number of incremental steps to include in a step gradient must be judged empirically based on the resolution achieved. Ideally (as in the procedure described here), three steps should be used in which all weakly bound materials are desorbed and eluted in the first gradient step using wash buffer, the target protein is eluted in the second gradient step using elution buffer, and all strongly adsorbed materials are eluted in the third gradient step using regeneration buffer. A minimum increment of 50 mM NaCl is recommended for experiments using step-gradient elution with increasing salt concentration. Steps in the gradient may be added, omitted, or modified as determined empirically.

Materials

QAE Sephadex A-25 (Amersham Pharmacia Biotech) or equivalent anion-exchange gel

Binding buffer: 20 mM Tris·Cl, pH 7.5 (or other buffer as determined empirically; see Support Protocol 1)

Protein sample to be purified

Wash buffer: 20 mM Tris·Cl (pH 7.5)/100 mM NaCl (or other buffer/salt solution as determined empirically; see Support Protocol 1)

RCU IASI CENTRAL UNIVERSITY LIBRARY

Elution buffer: 20 mM Tris·Cl (pH 7.5)/350 mM NaCl (or other buffer/salt solution as determined empirically; see Support Protocol 1)
Regeneration buffer: 20 mM Tris·Cl (pH 7.5)/2 M NaCl (also see Support Protocol 5)

Boiling water bath (optional)
500-ml sintered-glass filter funnel, medium porosity
Three 2000-ml side-arm flasks
Conductivity meter

Swell and equilibrate ion-exchange gel

1. Add 10 g QAE Sephadex A-25 to 1 liter binding buffer and swell 2 days at room temperature or 2 hr in a boiling water bath.

   The volume of swollen gel will be ~70 ml.

2. Mount 500-ml sintered-glass filter funnel on 2000-ml side-arm flask and apply suction.

   Centrifugation (~5000 × g, 1 min) may be used instead of filtration to collect the gel, and may be preferred for processing small sample volumes. It is also possible to simply allow the gel to settle under gravity, then decant or aspirate the supernatant; this may be preferable for very large-scale operations.

3. Gently swirl swollen gel to resuspend. Pour gel slurry into funnel as fast as the fluid level in funnel permits, allowing buffer to collect in flask. Continue until all gel has been collected. Release suction after all buffer has been removed.

   IMPORTANT NOTE: *Never use a magnetic stir-bar to resuspend chromatography medium. This can damage beads by grinding them against the bottom of the vessel, resulting in fine particles that can slow the filtration process.*

4. Add 200 ml binding buffer to funnel and resuspend gel using a stirring rod. Allow resuspended gel to stand for 5 min, then apply suction to remove buffer.

5. Repeat step 4 at least three times to ensure equilibration.

   The gel is considered equilibrated when the pH and salt concentration of the eluant are the same as those of the binding buffer. If the procedures here are followed, there is little need to measure pH and salt concentration of the eluant because the gel is swollen and washed in binding buffer and the chance of error is very small. The worst-case scenario is that the target protein will not bind (see Troubleshooting). The repeated washings are more for the removal of fines than for adjustment of pH or salt concentration.

6. Add enough binding buffer (~100 ml) to produce an ~50% (v/v) slurry and allow gel to stand in funnel until sample has been prepared.

Adsorb sample to gel

7. Adjust pH and salt concentration of protein sample to initial optimal values.

   For a pilot experiment to determine optimal initial values for pH and salt concentration, see Support Protocol 1.

   Samples prepared by salt precipitation may require desalting prior to ion exchange (see UNIT 8.3). The sample can be dialyzed against the binding buffer. Also, the salt concentration of a sample can be reduced by adding distilled water until a desired salt concentration is achieved, as measured by a conductivity meter.

8. Combine gel and sample in 2000-ml beaker or wide-mouth flask.

   The ~50% gel slurry is swirled and poured from the funnel; transfer may be aided with a rubber policeman, spoon, stirring rod, or wash bottle containing binding buffer.

BCU BIOSCI CENTRAL UNIVERSITY LIBRARY

9. Gently mix sample and gel by swirling every 15 min or shake on a platform shaker at sufficient rate to maintain gel in suspension. Allow 1 to 2 hr for binding at room temperature or 3 to 4 hr at 4°C.

   IMPORTANT NOTE: *Excessive shaking may result in foaming and possible denaturation of the target protein.*

10. Collect gel by filtration as in step 3. Save filtrate for assay.

    This filtrate is saved in case the target protein did not bind. All filtrates should be kept until the fraction containing the target protein has been identified. Storage conditions depend on the stability of the target protein; as a general rule they should be refrigerated to minimize microbial growth. Bacteriostatic agents may be added for prolonged storage.

11. Add 100 ml binding buffer to funnel and resuspend gel using a stirring rod. Allow resuspended gel to stand for 5 min, then apply suction to remove buffer. Repeat three or four times, pooling all washings with the filtrate from step 10.

    The gel containing the bound sample may be packed in a column for subsequent elution steps (see Basic Protocol 2).

Elute with step gradient of increasing salt concentration

12. Transfer the sintered-glass funnel to the top of a clean 2000-ml side-arm flask.

13. Add an equal volume of wash buffer to gel in funnel and resuspend using a stirring rod. Allow resuspended gel to stand for 5 min, then apply suction to remove buffer. Save filtrate.

    The wash buffer is the first step of the gradient. The filtrate will contain sample components that were weakly adsorbed to the gel (see annotation to step 10).

14. Measure absorbance of filtrate at 280 nm using wash buffer as blank.

15. Repeat steps 13 and 14 until the last filtrate shows no significant absorbance at 280 nm. Pool and save the filtrates.

16. Transfer the sintered-glass funnel to the top of a clean 2000-ml side-arm flask.

17. Add an equal volume of elution buffer to gel in funnel and resuspend using a stirring rod. Allow resuspended gel to stand 5 min, then apply suction to remove buffer. Save filtrate.

    The elution buffer is the second step of the gradient. The filtrate will contain the sample components that were more strongly adsorbed to the gel and should include the target protein.

18. Measure the absorbance of the filtrate at 280 nm using elution buffer as a blank.

19. Repeat steps 17 and 18 until the last filtrate shows no significant absorbance at 280 nm. Pool and save the filtrates for assay and subsequent purification of the target protein.

    If gel is to be reused, continue with remaining steps. Otherwise, discard the gel.

Regenerate ion-exchange medium for reuse

20. Transfer the sintered-glass funnel to the top of a clean 2000-ml side-arm flask.

21. Add an equal volume of regeneration buffer to gel in funnel and resuspend using a stirring rod. Allow resuspended gel to stand for 5 min, then apply suction to remove buffer. Repeat five times and discard filtrates.

    The regeneration buffer removes strongly bound materials from the gel. See Support Protocol 5 for additional considerations in regenerating ion-exchange media.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

22. Repeat step 11 for a total of five washes to reequilibrate the gel with binding buffer.

23. Check the pH and conductivity of the last filtrate to ensure that the gel is properly equilibrated.

See Support Protocol 5 for information on storing ion-exchange media.

pH-BASED STEP-GRADIENT ELUTION

ALTERNATE PROTOCOL

The net charge of a protein is pH dependent. Therefore, altering the pH of the mobile phase to make it closer to the pI of a protein can change its net charge, causing it to desorb and elute from an ion exchanger (see Figure 8.2.1). Continuous pH gradients are very difficult to produce at constant salt concentration because charge characteristics of sample components, buffering ions, and ion-exchange media depend on the pH of the system. pH-based step gradients are much easier to produce and more reproducible. For anion-exchange media, elution occurs when the pH is decreased. For cation exchange, the pH is raised for elution.

The first basic protocol can be modified for pH-gradient elution by selecting a buffer at a pH suitable for elution, based on results obtained in a pilot experiment (see Support Protocol 1). This elution buffer is then used in steps 17 to 19 of the first basic protocol. Incubation times and buffer volumes should be increased by 20% when using pH elution.

When scouting methods for ion exchange, it is best to start with changes in salt concentration (see Basic Protocol 1) as this technique is simpler and more reproducible. Elution with pH change is only recommended when the ion-exchange behavior of the sample is well known and the resolution required cannot be attained with a change in salt concentration. pH elution may also be appropriate in cases where it provides a superior ionic/pH environment for loading in the next chromatographic step. A combination of increasing salt concentration and pH change may also be used for elution.

COLUMN CHROMATOGRAPHY WITH LINEAR GRADIENT ELUTION

BASIC PROTOCOL 2

Column chromatography is generally preferred to batch chromatography (see Basic Protocol 1), especially where high resolution is required, although it accommodates smaller sample volumes. Column chromatography requires specialized equipment to achieve high resolution, including a column containing the medium and a fluid-delivery system appropriate for the pressure and flow rate at which the column is to be operated. It is the technique preferred for the intermediate purification and polishing stages of protein purification (*UNIT 8.1*). Also in contrast to the first basic protocol, this technique uses a linear gradient for elution. Although more difficult to produce than step gradients (see Basic Protocol 1), linear gradients lead to better resolution (see Support Protocol 3).

The example presented here uses a RESOURCE Q anion-exchange column from Amersham Pharmacia Biotech, which may be used with either FPLC (fast protein liquid chromatography) or HPLC (high-performance liquid chromatography) systems. Optimal conditions for other columns should be obtained from the manufacturer. Procedures mentioned in the protocol steps should be carried out according to the manufacturer's instructions for the particular chromatography system being used.

NOTE: All buffers, media, and other system components should be filtered, degassed, and equilibrated to the same temperature before use.

BCU IAN CENTRAL UNIVERSITY LIBRARY

Materials

Liquid chromatography system (FPLC or HPLC)
Elution buffer: binding buffer (see Basic Protocol 1 and Support Protocol 1) containing 1 M NaCl
Binding buffer (see Basic Protocol 1 and Support Protocol 1)
RESOURCE Q chromatography column (1-ml packed bed volume; Amersham Pharmacia Biotech)
Protein sample to be purified

Conductivity meter
0.22-µm filter

Prepare chromatography system

1. Set up the liquid chromatography system according to manufacturer's instructions, without the column in-line.
2. Test system performance by running a blank gradient ranging from 0% to 100% elution buffer in 20 ml at a constant flow rate of 5 ml/min.

   See Figure 8.2.2 for a diagram of a typical column chromatography system. The gradient is formed by placing binding and elution buffer in the appropriate buffer reservoirs (see Support Protocol 3 for detailed discussion of continuous gradient formation).

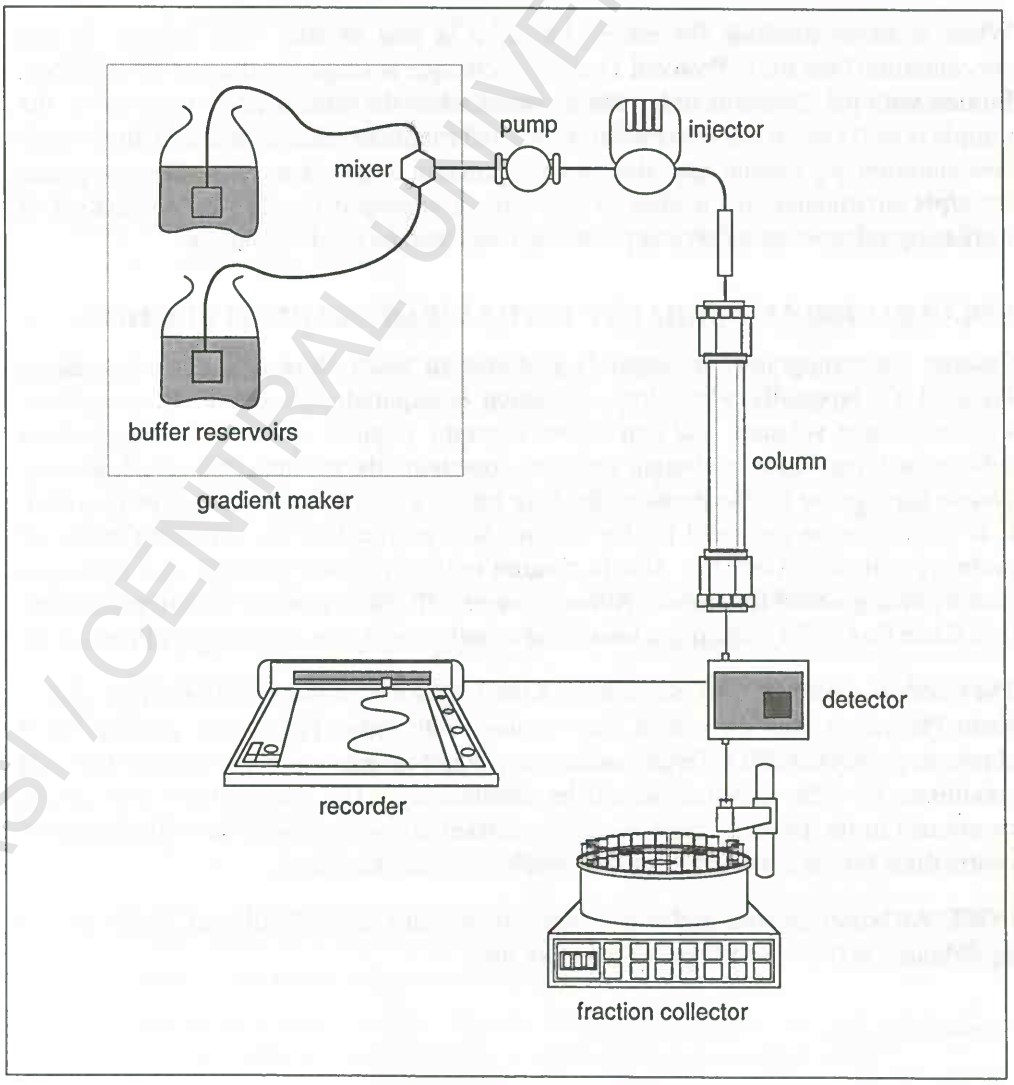

Figure 8.2.2 Liquid column chromatography system with gradient maker.

PCU IASI / CENTRAL UNIVERSITY LIBRARY

Stability of the column at extremes of pH must be considered when choosing binding and elution buffers. The working stability of the RESOURCE Q column is pH 2 to 12, and the stability for cleaning is pH 1 to 14.

The flow rate for the test should be appropriate for the column to be connected. For the RESOURCE Q column, the recommended flow rate is 1 to 10 ml/min and the maximum operating pressure is 4 bar.

3. Test for system leaks and ascertain monitor stability according to system documentation. Test accuracy of gradient composition using conductivity meter.

Adding 0.1% (v/v) acetone to the elution buffer used in step 2 will allow observation of gradient composition at 280 nm using the UV monitor. Do not include acetone in the elution buffer used for the chromatographic run.

Prepare column

4. Purge system with binding buffer to remove any air, then install column in system.

New columns may require precycling prior to use; consult product documentation. Used columns may require cleaning or removal of storage solution prior to use (see Support Protocol 4).

5. Wash column with 5 V_c (5 ml for RESOURCE Q column) of elution buffer at a flow rate of 5 ml/min and check for leakage.

V_c refers to the packed bed volume of a column and is calculated according to the equation $V_c = \pi r^2 \times L$, where r is the radius of the column and L is the bed height (i.e., the height of the packed medium in the column). As the RESOURCE Q column used here has a packed bed volume of 1 ml, the column is washed with 5 ml of elution buffer. Consult product literature to find V_c for other columns.

6. Equilibrate column with 5 to 10 V_c of binding buffer at 5 ml/min. Collect one fraction at the end of the equilibration stage and measure pH and conductivity to ensure the pH and salt concentration of the fraction are the same as that of binding buffer.

If the pH and salt concentration of the fraction are not the same as that of the binding buffer, continue passing binding buffer through the column until equilibration is complete.

Purify protein sample and regenerate column

7. Adjust pH and salt concentration of sample to binding conditions determined in Support Protocol 1. Filter sample prior to injection using a 0.22-μm filter to remove particulates that may clog system or column.

For initial experiments, a sample containing 25 mg total protein is appropriate.

For columns packed with beads of average diameter ≥90 μm, a 1-μm filter may be used; for columns packed with beads of average diameter 34 to 90 μm, a 0.45-μm filter may be used. The 0.22-μm filter is appropriate for columns packed with beads of average diameter <34 μm (e.g., the RESOURCE Q). Alternatively, the sample may be centrifuged 5 min at 20,000 × g to remove particulates.

8. Inject sample into column by opening sample injection valve. Begin fraction collection.

Fractions of 1-ml volume are generally sufficient.

The flow rate during sample injection should be reduced for concentrated samples. It may be increased for dilute samples.

9. After all sample is injected, wash column with 3 to 5 V_c of binding buffer at 5 ml/min to remove unbound or weakly bound materials.

The monitor signal should be allowed to approach the baseline before continuing.

BOULAY CENTRAL UNIVERSITY LIBRARY

10. Elute with a linear gradient of 0% to 100% elution buffer in 20 V_c (20 ml).

    Sample-injection valves should be closed to reduce the system dead volume before beginning gradient.

11. Regenerate column by washing with 5 V_c of elution buffer.

12. Reequilibrate column by washing with 5 to 10 V_c of binding buffer.

13. Assay fractions for target protein. Pool fractions containing target protein for further processing.

SUPPORT PROTOCOL 1

TEST TUBE PILOT EXPERIMENT TO DETERMINE STARTING CONDITIONS FOR ION-EXCHANGE CHROMATOGRAPHY

Before beginning an ion-exchange separation (Basic Protocol 1 or 2), the pH and salt concentration required for binding the target protein and the change in pH or salt concentration required for elution must be determined empirically. Once the initial binding conditions have been determined, the available protein capacity (for batch chromatography) is determined to predict the amount of medium that must be used for a given amount of sample. Dynamic capacity (for column chromatography) may be determined as in Support Protocol 2. This protocol is most appropriate when the sample is not strictly limited—e.g., when milligram quantities of a recombinant protein are available. If sample is scarce, a column method should be substituted.

As illustrated in Figure 8.2.3, aliquots of the protein-containing sample to be purified are mixed in test tubes with small quantities of ion-exchange gel that have been equilibrated with a series of buffers of different pH. The optimal binding pH is chosen on the basis of disappearance of target protein in the supernatant at a certain point in the series, then the process is repeated with another series of test tubes containing gel equilibrated with a series of salt solutions of different concentrations. The optimal salt concentrations for binding and elution are chosen, respectively, on the basis of disappearance, then reappearance at another salt concentration, of protein in the supernatant. Finally, aliquots containing increasing protein concentrations are mixed with the gel in a buffer under the optimal binding pH and salt concentrations previously determined. The available capacity of the gel is then determined on the basis of the point where unbound protein appears in the supernatant.

The stability of the target protein at extremes of pH must be considered—i.e., the pH range chosen for the purification should be compatible with retention of structure and activity. In general, this can be evaluated with a crude preparation by incubating aliquots at a series of pH values, then performing the structural or functional assay at the optimal pH value.

NOTE: The method presented here is for anion exchange with increasing salt concentration for elution. Differences for cation exchange are noted where appropriate. Select cation-exchange buffers from Table 8.2.1.

Materials

20 mM piperazine, pH 5.0, 5.5, and 6.0 (prepare from 100 mM stock)
20 mM 1,3-bis[tris{hydroxymethyl}methylamino]propane (bis-Tris propane), pH 6.5 and 7.0 (prepare from 100 mM stock)
20 mM Tris·Cl, pH 7.5, 8.0, and 8.5 (*APPENDIX 2E*; prepare from 100 mM stock)
Q Sepharose Fast Flow (50% slurry in 20% ethanol; Amersham Pharmacia Biotech) or equivalent anion exchange resin in appropriate buffer
Protein sample to be purified, containing known quantity of target and total protein

BCU IAS LIBRARY CENTRAL UNIVERSITY

4 M NaCl

15-ml test tubes
Centrifuge with rotor accommodating 15-ml test tubes (optional)

Determine optimal binding pH

1. Set up a series of test tubes, numbered 1 to 8, containing different buffers as follows:

   tube 1: 5 ml 20 mM piperazine, pH 5.0
   tube 2: 5 ml 20 mM piperazine, pH 5.5
   tube 3: 5 ml 20 mM piperazine, pH 6.0
   tube 4: 5 ml 20 mM bis-Tris propane, pH, 6.5
   tube 5: 5 ml 20 mM bis-Tris propane, pH 7.0
   tube 6: 5 ml 20 mM Tris·Cl, pH 7.5
   tube 7: 5 ml 20 mM Tris·Cl, pH 8.0
   tube 8: 5 ml 20 mM Tris·Cl, pH 8.5.

2. Shake bottle of Q Sepharose Fast Flow to resuspend gel. Pour 25 ml of gel slurry into a graduated cylinder, then allow gel to settle. Adjust volume of liquid above gel to equal the volume of settled gel (i.e., prepare 50% slurry), then resuspend with a glass stirring rod.

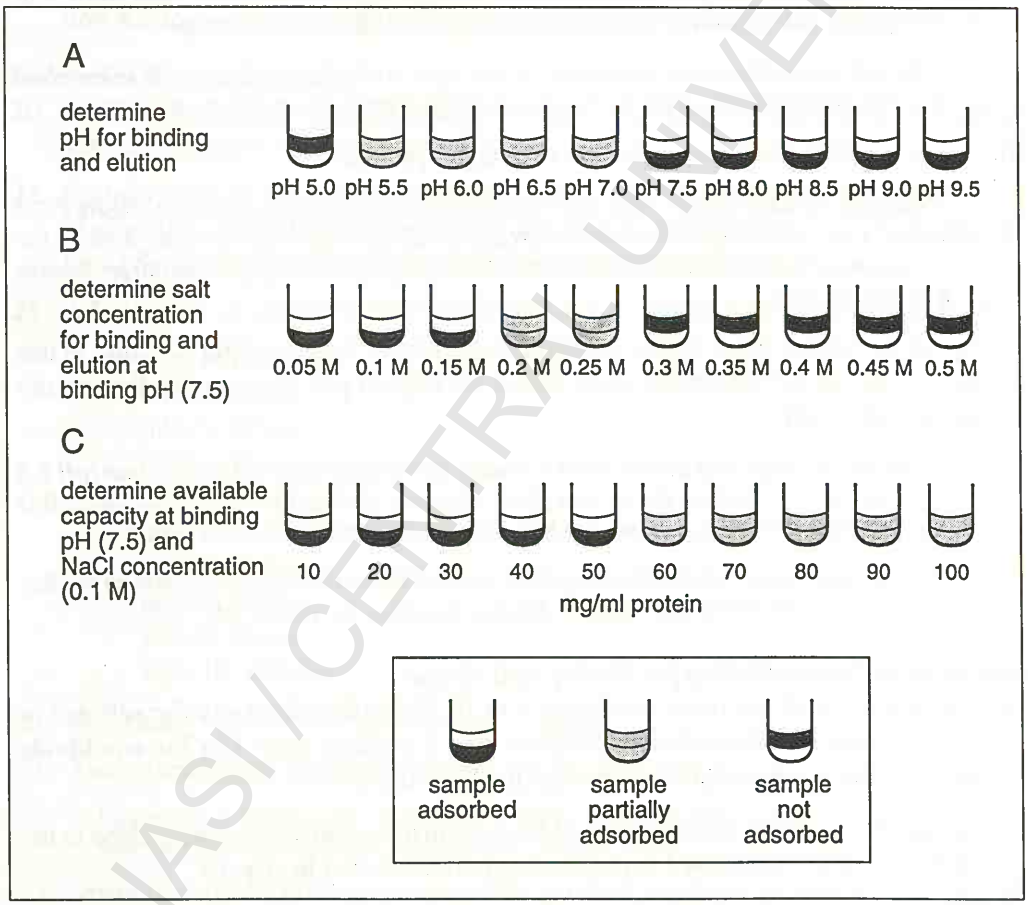

Figure 8.2.3 Results of a typical test tube pilot experiment for selecting initial conditions for anion-exchange chromatography. Series of tubes with protein and ion-exchange medium at (**A**) varying pH (to select binding and elution pH); (**B**) constant pH, varying NaCl concentration (to select binding and elution salt concentrations); (**C**) constant pH and NaCl concentration, varying protein concentration (to determine available capacity). The binding pH here will be ≥7.5; the elution pH will be ≤5.0; the binding salt concentration will be ≥0.15 M; the elution salt concentration will be >0.3 M; and the available capacity will be >50 mg/ml.

BANASTHALI VIDYAPITH CENTRAL UNIVERSITY LIBRARY

3. Add 2 ml of 50% slurry of Q Sepharose Fast Flow to each tube and mix.

   SP Sepharose Fast Flow (Amersham Pharmacia Biotech) or equivalent may be used for cation exchange.

4. Allow gel to settle to bottom of tube or centrifuge 1 min at ~5000 × *g*, room temperature.

5. Decant supernatant from each tube and replace with 5 ml of the same buffer added in step 1. Gently shake or vortex to resuspend gel, then let tubes stand 2 min.

6. Repeat steps 4 and 5 three times to equilibrate gels in each tube.

7. Decant supernatants and resuspend each equilibrated gel in 1 ml of the same buffer added in step 1.

8. Set up eight identical aliquots (≥1 ml) of the protein to be purified in tubes numbered 1 to 8, each containing 0.1 to 1 mg total protein. Adjust the pH of each to obtain eight different pH values corresponding to those of tubes 1 to 8 in step 1.

   Quantity of protein to be used depends on availability of sample and extinction coefficient of target protein. pH may be adjusted by titrating with acid or base using pH paper or by diluting 1:1 with buffer of desired pH.

9. Add the corresponding pH-adjusted protein aliquot to each of the 8 tubes from step 7. Mix gently for 10 min by periodic swirling, then allow gel to settle.

   If the salt concentration of the sample is too high, no binding will occur. It is therefore recommended that the sample be desalted into the appropriate buffer as in UNIT 8.3.

10. Assay supernatant from each tube for the target protein.

    Measuring the absorbance of the supernatant at 280 nm is usually sufficient. Figure 8.2.3 shows a set of possible results. A decrease or absence of target protein activity (or absorbance) in the supernatant indicates binding. Specific assays for the target protein may also be used.

11. Select the lowest pH at which the highest quantity of target protein is bound to use as the binding pH for further work. Select the highest pH where no binding occurs as the elution pH.

    For anion exchange, it is best to select a binding pH no more than 0.5 to 1 pH unit (pH 7.5 to 8.0 in Fig. 8.2.3) above the highest pH at which no binding occurs. If too high a pH is chosen, elution becomes difficult and high salt concentrations may be required.

    For cation exchange, select a binding pH 0.5 to 1 unit below the lowest pH where no binding occurs. Select the lowest pH where no binding occurs as the elution pH.

Determine salt concentration for binding and elution

12. Set up a series of test tubes, numbered 1 to 10. Using the binding buffer selected in step 10 in place of the different buffers in step 1, perform steps 1 to 7 to equilibrate the Q Sepharose Fast Flow with buffer in all ten tubes.

13. To each tube, add the same amount of the protein to be purified that was added to the tubes in step 8, equilibrated in the binding buffer selected in step 10.

14. Mix contents of tubes gently for 10 min, then allow gel to settle.

15. Decant supernatants from each tube and discard. Wash gel two times with 5 ml of the binding buffer, allowing the gel to settle and decanting the supernatants after each addition of buffer.

PCU IASI CENTRAL UNIVERSITY LIBRARY

16. Add 2 ml of the binding buffer to each tube, then sequentially add water and 4 M NaCl to each tube as follows:

    tube 1: 1.90 ml H_2O and 0.10 ml 4 M NaCl (0.10 M NaCl final)
    tube 2: 1.80 ml H_2O and 0.20 ml 4 M NaCl (0.20 M NaCl final)
    tube 3: 1.70 ml H_2O and 0.30 ml 4 M NaCl (0.30 M NaCl final)
    tube 4: 1.60 ml H_2O and 0.40 ml 4 M NaCl (0.40 M NaCl final)
    tube 5: 1.50 ml H_2O and 0.50 ml 4 M NaCl (0.50 M NaCl final)
    tube 6: 1.40 ml H_2O and 0.60 ml 4 M NaCl (0.60 M NaCl final)
    tube 7: 1.30 ml H_2O and 0.70 ml 4 M NaCl (0.70 M NaCl final)
    tube 8: 1.20 ml H_2O and 0.80 ml 4 M NaCl (0.80 M NaCl final)
    tube 9: 1.10 ml H_2O and 0.90 ml 4 M NaCl (0.90 M NaCl final)
    tube 10: 1.00 ml H_2O and 1.00 ml 4 M NaCl (1.00 M NaCl final).

17. Mix contents of tubes gently for 10 min, then allow gel to settle.

18. Assay supernatant from each tube for the target protein.

    Figure 8.2.3 shows a set of possible results. Presence of target protein in the supernatant indicates elution of the target protein.

19. Select the highest salt concentration at which no elution occurs as the maximum salt concentration allowable for binding target protein and for washing away unbound sample components. Select a salt concentration at least 0.05 M above the concentration where no protein binds to the gel as the salt concentration for elution.

Determine available capacity

20. Prepare a buffer/salt solution with the binding pH selected in step 10 and the binding salt concentration selected in step 19.

21. Set up a series of test tubes numbered 1 to 10. Using the buffer/salt solution prepared in step 20 in place of the different buffers in step 1, perform steps 1 to 7 to equilibrate the Q Sepharose Fast Flow with buffer/salt solution in all ten tubes.

22. Add aliquots of sample to each tube to obtain the following amount of target protein:

    tube 1: 10 mg
    tube 2: 20 mg
    tube 3: 30 mg
    tube 4: 40 mg
    tube 5: 50 mg
    tube 6: 60 mg
    tube 7: 70 mg
    tube 8: 80 mg
    tube 9: 90 mg
    tube 10: 100 mg.

23. Mix gently for 10 min, then allow gel to settle.

24. Assay supernatant from each tube for the target protein.

    Figure 8.2.3 shows a set of possible results. Presence of target protein in supernatant indicates that the available capacity has been exceeded.

25. Select the highest protein concentration at which the target protein does not appear in the supernatant as the available capacity.

    Calculate the amount of ion-exchange medium needed for batch purification based on 50% of the available capacity (defined in UNIT 8.1). If a column system is used in pilot experiments, however, it is best to determine the dynamic capacity of the medium (see Support Protocol 2). However, 20% of the available capacity is a safe and reasonable starting point for pilot experiments using column chromatography.

BCU/NSI/CENTRAL UNIVERSITY LIBRARY

MEASUREMENT OF DYNAMIC (COLUMN) CAPACITY AND BREAKTHROUGH CAPACITY OF ION-EXCHANGE COLUMNS

For chromatographic separations that will be performed on a routine basis as well as separations that will be scaled up, it is necessary first to optimize conditions with respect to resolution and to determine the capacity of the medium with respect to the target protein (see Support Protocol 1). Knowledge of the capacity allows optimal use of the gel medium in terms of cost and yield, and also allows working limits to be set on the sample load to ensure robustness of a particular purification step. After capacity has been determined, the separation can be optimized with respect to time. There are two capacity terms that commonly appear in the literature (in addition to available capacity; also see Support Protocol 1 and *UNIT 8.1*): dynamic capacity and breakthrough capacity.

The dynamic (or column) capacity is the capacity of an ion-exchange column under defined conditions of flow rate, pH, salt concentration and sample concentration. The breakthrough capacity (Q_B) for a system is obtained by calculating the amount of protein that has been absorbed by the column when the sample is first detected in the effluent, or when the recorder signal reaches some arbitrarily defined percent of full-scale deflection. Breakthrough capacity values at 50% full-scale deflection (Q_{B50}) are commonly reported in the literature. However, it is generally recommended to use only 10% to 20% of the published Q_B as the practical capacity of the column to ensure high recovery of the target protein.

Additional Materials (also see Basic Protocol 2)

Ion-exchange gel of unknown capacity, and column
Elution buffer capable of eluting target protein in single step of salt concentration or pH (e.g., 2 M NaCl; see Support Protocol 1)

1. Pack a defined amount of the ion-exchange gel into the column.

   See UNIT 8.3 for guidelines on column packing. Normally, a quantity of gel sufficient to give a packed bed volume of ~1 ml is sufficient. In the case of a prepacked column, the amount of gel is predetermined. The packed bed volume (V_c) is calculated according to the equation $V_c = \pi r^2 \times L$, where r is the radius of the column and L is the bed height (i.e., the height of the packed medium in the column).

2. Prepare chromatography system and column (see Basic Protocol 2, steps 1 to 6) using the optimal binding and elution conditions determined in Support Protocol 1.

   Do not exceed 75% of the flow rate used for packing. The effect of flow rate on capacity should be determined in a true optimization.

3. Prepare protein solution and inject into column (see Basic Protocol 2, steps 7 and 8). Apply solution continually until the recorder shows >50% full-scale deflection, then stop.

   The absorbance of the binding buffer corresponds to 0% and the absorbance of the sample corresponds to 100% full-scale deflection.

4. Wash column with binding buffer until 0% full-scale deflection is approached.

5. Elute proteins with a buffer providing a single-step increase in salt concentration or pH. Continue collecting eluant until recorder shows ≤2% full-scale deflection, then pool fractions.

   A typical chromatogram for this procedure is presented in Figure 8.2.4.

6. Assay pooled fractions from step 5 for target protein. Calculate maximum amount of protein (A) that can be bound to the column according to the equation $A = C_p \times V$,

BCU IASI / CENTRAL UNIVERSITY LIBRARY

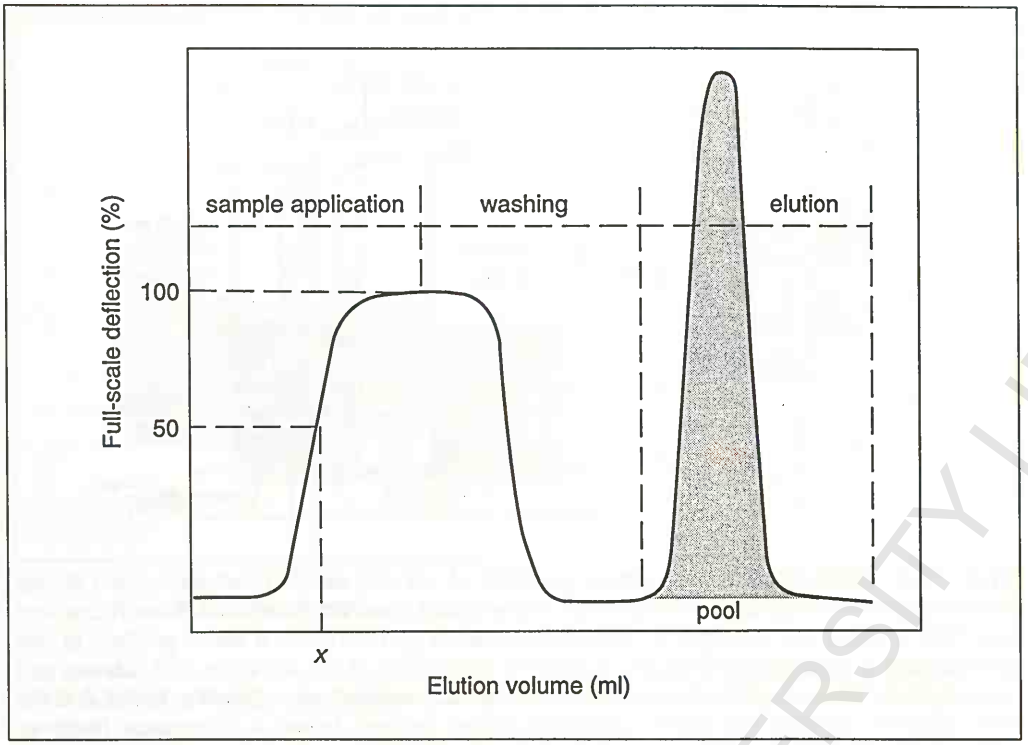

Figure 8.2.4 Typical chromatogram for determining the capacity of an ion-exchange column. The volume of eluant (x) at 50% full-scale deflection is used to calculate the breakthrough capacity (Q_{B50}).

where C_p is the protein concentration of the pooled fractions (mg/ml) and V is the volume of the pooled fractions (ml).

7. Calculate the column (dynamic) capacity (mg/ml) using the equation dynamic capacity = A/V_c.
8. Calculate breakthrough capacity (Q_{B50}) using the equation $Q_{B50} = (C_s \times x)/V_c$, where C_s is the concentration of protein in the original sample and x is the volume of sample that has been applied to the column at the point where 50% full-scale deflection has been attained.

If Q_{B50} greatly exceeds the dynamic capacity, then the target material may still be adsorbed on the column, and the elution conditions should be reexamined.

See Figure 8.2.4 for graphical depiction of these variables.

GRADIENT-FORMATION TECHNIQUES

SUPPORT PROTOCOL 3

Simple Gradient Mixers

Gradient mixers of the type shown in Figure 8.2.5 can generate linear pH or salt gradients in gravity-based or one-pump chromatography systems. Similarly designed gradient mixers used for casting electrophoresis gels may also be used for chromatography. The reservoir closest to the column is filled with the binding buffer and the second reservoir is filled with an equal volume of the elution buffer. The gradient begins when the valve between the two reservoirs is opened. Continuous mixing is required in the reservoir closest to the column to ensure gradient linearity and reproducibility.

BOSTON UNIVERSITY CENTRAL LIBRARY

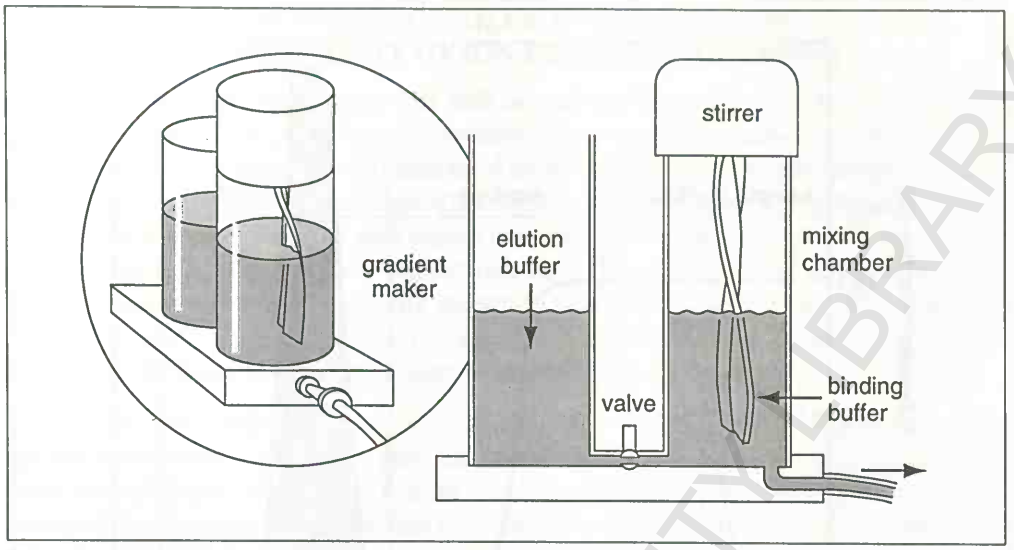

Figure 8.2.5 Gradient mixer for forming gradients of pH and salt concentration used during ion-exchange chromatography. The apparatus shown is an Amersham Pharmacia Biotech Gradient Mixer GM-1, which can be used for preparing gradients up to 500 ml. A linear gradient of salt concentration is produced by filling the reservoirs with buffers at the same pH and different salt concentration. The mixing chamber contains the lower-salt-concentration (binding) buffer, and the other chamber contains the higher-salt-concentration (elution) buffer. A continuous linear or nonlinear pH gradient may be produced by filling the reservoirs with buffers at the same salt concentration and different pH. A gradient of increasing pH is used for cation-exchange separations, and a gradient of decreasing pH is used for anion-exchange separations. The buffer chambers are joined by a channel controlled by a valve, and outflow from the mixing chamber is controlled by another valve.

Gradient Mixing with Multichannel Peristaltic Pumps

Peristaltic pumps that can accommodate three or more pumping channels simultaneously (Fig. 8.2.6) can be used to form linear or complex gradients (see Critical Parameters). Linear gradients are easily formed by using the same size tubing for all channels, pumping with one channel from the elution buffer reservoir to the binding buffer reservoir, and pumping with the other two channels from the binding buffer reservoir to the column. Continuous mixing is required in the binding buffer reservoir closest to the column to ensure gradient linearity and reproducibility.

Switch-Valve-Based Gradient Mixing

Switch-valve-based gradient formation is useful for forming step, linear, and complex gradients (see Critical Parameters). Gradients are formed by proportioning variable amounts of binding buffer and elution buffer through a single three-way valve using a system controller. When programmed to deliver 10% elution buffer, the controller will open the valve port for binding buffer 90% of the time and the port for elution buffer 10% of the time. As higher switching rates are required for lower flow rates to ensure gradient accuracy, high-quality system controllers will vary the rate at which the valve switches (i.e., the number of switching events per unit time) as a function of flow rate. A dynamic mixer should be included in the flow path just after the proportioning valve to ensure gradient accuracy. Switch-valve-based gradients are generally not very accurate from 1% to 10% elution buffer (90% to 99% binding buffer) or from 1% to 10% binding buffer (90% to 99% elution buffer). Therefore, the ionic strength of the binding and elution buffers may be adjusted to allow a gradient of the desired composition to be formed by mixing the two buffers in the range of 20% to 80% elution buffer (80% to 20% binding buffer).

PCU IAS CENTRAL UNIVERSITY LIBRARY

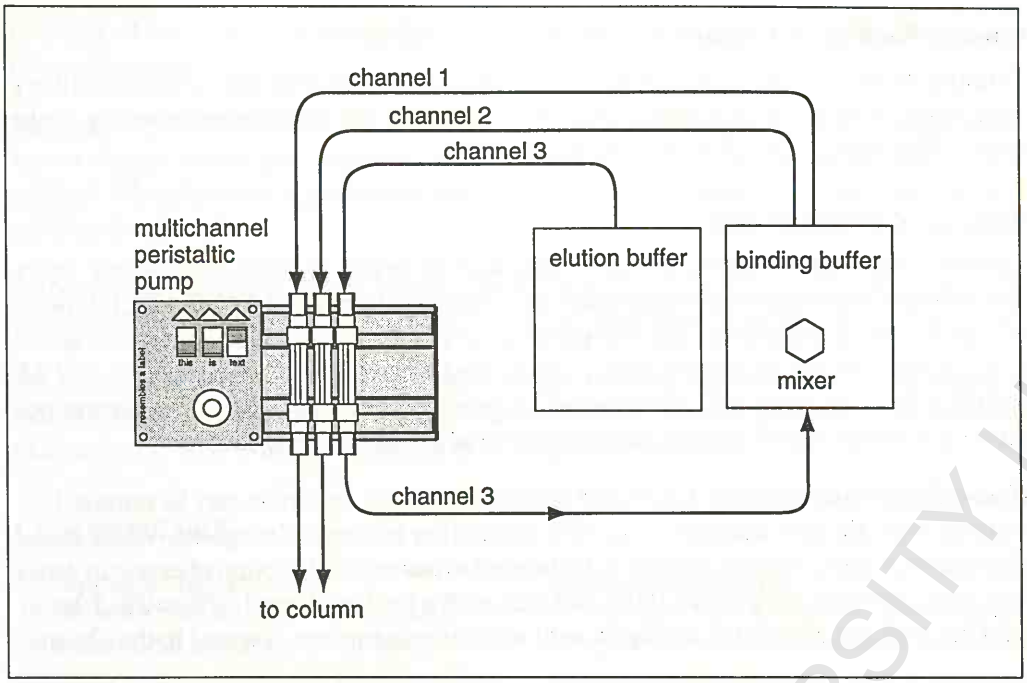

Figure 8.2.6 Peristaltic pump accommodating three pumping channels for continuous gradient formation.

Gradient Formation by Autoblending

Some chromatography systems allow gradient formation over a range of both pH and salt concentration. Four solvents—a high-pH buffer, a low-pH buffer, a concentrated salt solution, and water—are blended via four two-way valves. A system controller proportions the high- and low-pH buffers to achieve the desired pH gradient while simultaneously proportioning the concentrated salt solution and water to achieve the desired salt-concentration gradient. Gradients formed in this way are usually difficult to reproduce but may be useful for scouting initial binding and elution conditions.

Gradient Formation with Twin Pumps

Use of two positive-displacement pumps, as in HPLC and FPLC systems, provides the highest degree of accuracy, precision, and reproducibility in gradient formation. One pump delivers binding buffer while the other delivers elution buffer. A system controller allows gradient formation simply by controlling the flow rate of each pump. A dynamic mixer should be included in the flow path, after the pumps and before the column, to ensure gradient accuracy.

CLEANING AND REGENERATION OF ION-EXCHANGE MEDIA

SUPPORT PROTOCOL 4

Proper maintenance of chromatography media is as much an art as protein purification itself. Knowing what kind of contaminating material from the sample is bound to the column helps in selecting a regime for maintaining good column hygiene. It is best to practice preventative maintenance by regenerating the medium after every run, using a high-salt buffer or large change in pH, and periodically cleaning the column and checking the system flow characteristics. If any increase in column back-pressure is noted, the column should be cleaned as soon as possible. Once enough contaminant has bound to a column to reduce or block the flow, it is probably too late to save the medium without investing considerable time and effort.

BCIT LIBRARY / CENTRAL UNIVERSITY LIBRARY

Routine Washing of Columns and Media

Columns or bulk medium should be washed after every run with salt solution until an ionic strength of ≥2 M is reached. This should remove any substances bound by ionic forces. This is recommended after every run.

Removal of Contaminants

Alkali-soluble contaminants. Contaminants such as lipids, proteins, and nucleic acids can usually be removed by washing with 2 to 3 column volumes of 0.1 M NaOH, followed by 2 to 3 column volumes of Milli-Q-purified (or equivalent) distilled water and then 2 to 3 column volumes of binding buffer. Many media can tolerate brief exposure to 1 M NaOH, if harsher conditions are required to remove contaminants; however, manufacturer's guidelines should be consulted regarding pH stability of the medium.

Hydrophobic contaminants. Lipids and other hydrophobic materials may be removed by washing with alcohol solutions (e.g., 70% ethanol) or nonionic detergents. When using alcohols or organic solvents to remove hydrophobic materials, it is often effective to wash first with a gradient from 0% to 100% and then with a gradient from 100% to 0%. Repeat washing with the alternating gradients until no contaminants are detected in the eluant.

Metallic contaminants. Contamination with metals may cause blue or gray discoloration at the top of an ion-exchange column. These metals can originate from impurities in buffer salts or water, or they can leach from metallic system components in contact with buffer solutions. Metal contaminants may usually be removed by treating the column with several column volumes of 10 mM HCl (i.e., pH 2) saturated with EDTA. Manufacturer's guidelines should be checked for pH stability of medium and column before exposure to mild or strong acid solutions.

Precipitated materials. Precipitated materials that have accumulated in a column are very difficult to remove. Unless the precipitated material can be physically removed by removing the gel at the top of the column, the material will have to be resolubilized. Detergents, urea, and guanidine·Cl can be introduced to help dissolve contaminants. The viscosity of concentrated solutions used for cleaning may require very low flow rates. The column may be equilibrated and incubated in 6 M urea, then washed with distilled water and buffer. Degradative enzymes (e.g., proteases and lipases) may also be introduced in an attempt to degrade precipitates on the column; however, enzymatic cleaning can be quite expensive. It may be useful to reverse the direction of flow through the column (i.e., from bottom to top) when attempting to remove particulate material from the top of the bed.

SUPPORT PROTOCOL 5

STORAGE OF ION-EXCHANGE MEDIA

Bacterial and microbial growth can seriously interfere with the chromatographic properties of any chromatography medium and endanger the sample as well. Prior to storage, all media should be cleaned and sanitized. During prolonged experiments or storage (i.e., >24 hr at room temperature or 48 hr at 4°C), a bacteriostatic or antimicrobial agent should be added to the ion exchanger. Antimicrobials chosen to be added for storage should not bind to the ion exchanger and should be easily removed when the gel is to be reused. Azide is anionic and will bind to anion-exchange media.

Treatment with 1 M NaOH for 1 hr will sanitize most media by lowering the bacterial count 100-fold, and will help solubilize dead cells (Pharmacia Biotech, 1997). Storage of sanitized media in 0.1 M NaOH will not leave any toxic materials on the column—a significant consideration in pharmaceutical production. Manufacturer's guidelines should

RCU IAS / CENTRAL UNIVERSITY LIBRARY

be checked for stability of the medium and column in NaOH. Silica-based media will not tolerate high pH.

Exposure to 70% ethanol for 3 to 4 hr can be used to sanitize most media. Most ion-exchange media and columns can be stored for prolonged periods of time in 20% ethanol. Manufacturer's guidelines should be checked for stability of the medium and column in ethanol.

Effective antimicrobial agents appropriate for use with anion-exchange media include either 0.001% phenyl mercuric salts or 0.002% chlorhexidine, in weakly alkaline solution.

An effective antimicrobial agent for use with cation-exchange media is 0.005% merthiolate in weakly acidic solution. An agent that is effective for use with either anion or cation exchangers is 0.05% trichlorobutanol in weakly acidic solution.

COMMENTARY

Background Information

The first ion exchangers were synthetic resins designed for applications such as demineralization, water treatment, and recovery of ions from waste. Early ion-exchange resins were tightly cross-linked hydrophobic polymers, highly substituted with ionic groups, and had very high capacity for small ions. The high degree of cross-linking provided mechanical strength, but the limited porosity restricted use of these media with large molecules. In addition, the high charge density resulted in very strong binding, and the hydrophobic matrix tended to adsorb and denature labile biological materials. The first ion exchangers designed for use with biomolecules were developed by Peterson and Sober (1956). These cellulose-matrix ion exchangers were very hydrophilic and had little tendency to denature proteins, but had low capacities and poor flow characteristics. Modern ion-exchange media have very high capacity, often >100 mg/ml. Modern particle technology has significantly increased the mechanical strength and flow characteristics of ion-exchange media so that separations that once required hours or days may now be completed in a few minutes.

Ion-exchange can easily be coupled to other methods of protein separation in a multistep purification. Samples purified by ion exchange can typically be applied to a hydrophobic-interaction chromatography (HIC) medium simply by adding NaCl (or other salts) to a concentration sufficient for binding (*UNIT 8.4*). Samples to be further purified by chromatofocusing or an additional round of ion exchange will require desalting (*UNIT 8.3*). Samples may usually be applied directly to gel-filtration columns (*UNIT 8.3*) with no intervening treatment.

Critical Parameters

The most critical aspects of any ion-exchange experiment are selection of the appropriate ion-exchange medium and of the initial conditions for binding and elution of the target protein or contaminants. Once these parameters are selected, conditions can be optimized with respect to the three primary parameters of any chromatographic separation—i.e., resolution, capacity, and speed. These three parameters are mutually exclusive. Resolution will typically decrease when the sample load is increased and when the flow rate is increased (to increase speed). It is generally recommended that resolution be optimized first, then capacity, and finally speed.

Optimization of resolution

This parameter is most easily optimized by controlling the selectivity (*UNIT 8.3*) of the medium through manipulation of binding and elution conditions. Construction of chromatographic titration curves followed by optimization of the shape of the elution gradient is a common approach to achieving maximum resolution.

Chromatographic titration curves can be constructed by performing a series of anion- and cation-exchange experiments at different pH values as in Figure 8.2.7. For each of these experiments, the elution salt concentrations (in mM NaCl) for sample components A, B, and C are plotted on the *y* axis and the operating pH is plotted on the *x* axis. It is then simple to observe the pH ranges within which optimal resolution between the various sample components is achieved. The different sample components are usually detected by UV absorption, but may also be viewed by other means (e.g., fluorescence or bioactivity). Data for chroma-

BOSTON UNIVERSITY LIBRARY

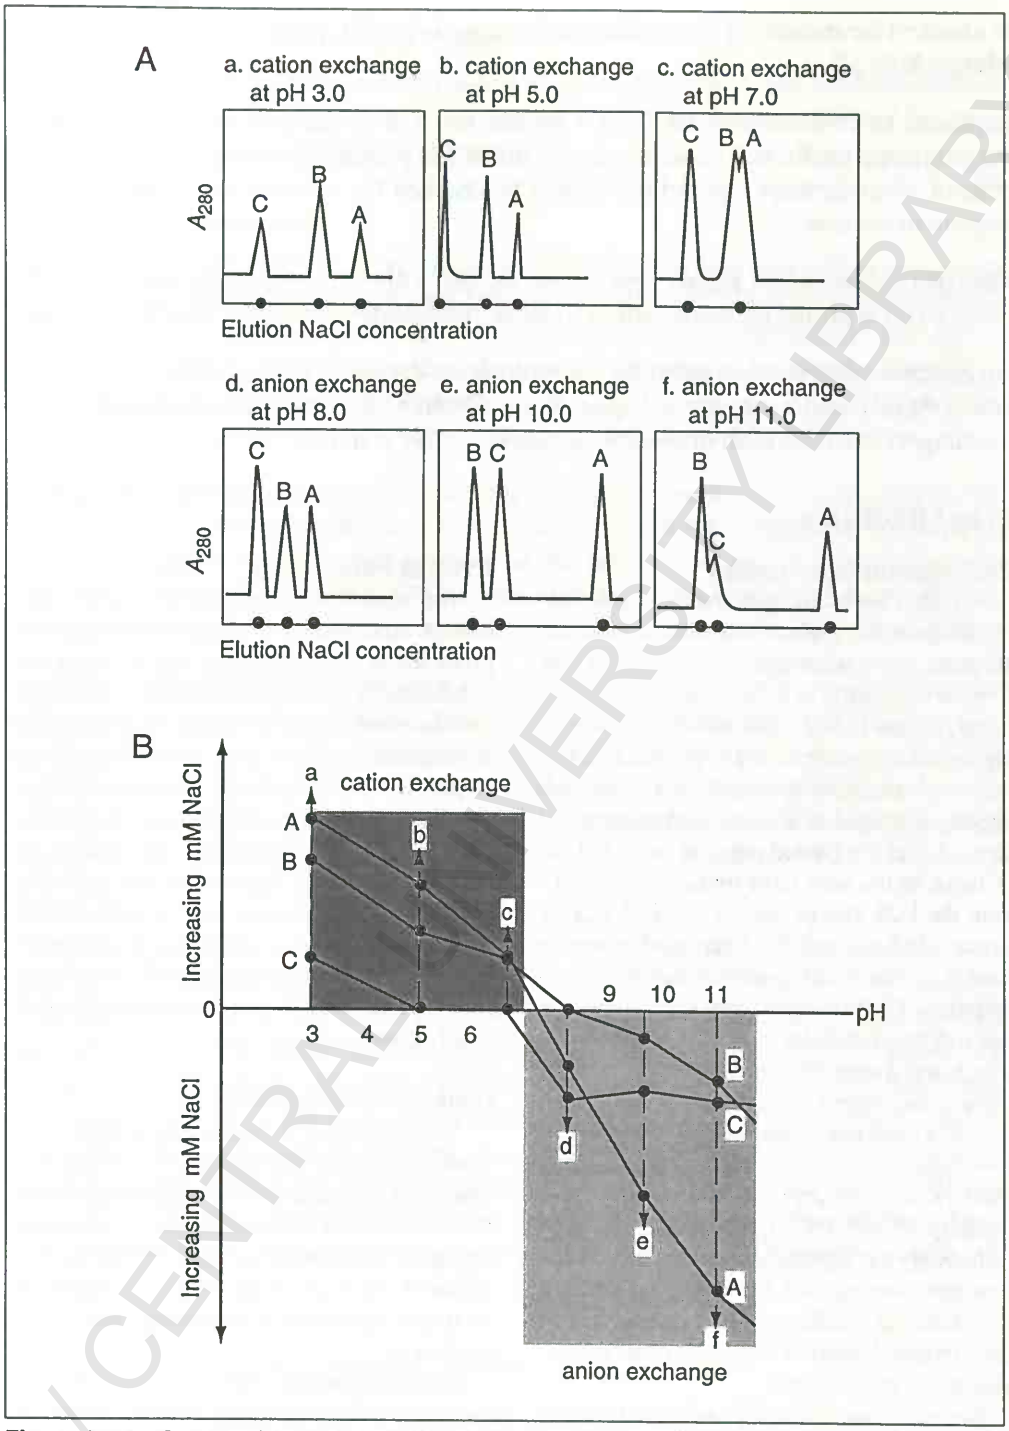

Figure 8.2.7 Construction of a chromatographic titration curve. (**A**) Six chromatographic separations (a to f) of a sample containing proteins A, B, and C are carried out at six different operating pHs using a linear gradient of increasing salt concentration. (**B**) The elution ionic strengths for components A, B, and C (*y* axis) are plotted against the operating pH (*x* axis) for experiments a to f. Note that the salt concentration in mM NaCl (*y* axis) is ascending in both directions. The optimal resolution with respect to component A occurs below pH 5 with cation exchange and above pH 9 with anion exchange.

BCU IAS / CENTRAL UNIVERSITY LIBRARY

tographic titration curves can often be generated by fast screening with low-volume gradients (e.g., 5 to 10 V_c) and low sample mass (e.g., <1 mg).

After optimization of resolution with respect to pH, the shape of the elution gradient can be optimized. A gradient can be conceptually divided into segments, and each segment may have a different gradient shape. Gradient shapes include linear, concave, convex, and step. Complex gradients are constructed by using different gradient shapes in consecutive segments. The slope (e.g., mM NaCl per minute) of a linear segment is constant, that of a concave segment continually increases, that of a convex gradient continually decreases, and that of a step gradient approaches infinity. Resolution between sample components in any segment can usually be increased by decreasing the gradient slope in that segment. However, decreasing the gradient slope will increase the peak volume during elution, the gradient volume, and the time of the separation. Step gradients can provide the most concentrated fractions, and are desirable when minimizing sample volume is of primary importance. Use of concave gradients in the initial part of a segment and convex gradients in the later part of a segment can improve resolution. The capabilities of available equipment must be considered in the construction of complex gradients. Use of simple gradients that do not stress the performance limits of the system will result in robust methods that are insensitive to small changes in sample or buffer composition and gradient shape, thereby increasing probability of success.

To construct a complete gradient profile, it is first necessary to identify the gradient range where desorption of the target protein occurs, as well as the gradient slope that provides optimal resolution. A single-step elution is then done at a salt concentration just below the range of where the target protein elutes, to remove weakly bound material. The target protein is then desorbed and eluted. A single-step elution at a high salt concentration will then remove tightly bound sample components and prepare the ion-exchange gel for regeneration. This approach, using step gradients before and after the range of interest, can provide simple, robust methods that are easy to scale up, and will save time and reagents.

Different ion-exchange media offer different selectivities (*UNIT 8.1*). If adequate resolution for a specific stage in a purification cannot be obtained with a specific ion-exchange medium, it may be desirable to select an alternate ion exchanger with a different functional group, or to use a different chromatographic technique at this stage in the separation. Salts other than NaCl may be used in elution, but there are no specific effects from different salts on the separation in ion-exchange chromatography, other than differences in concentration. Karlsson et al. (1998) provides a good review of the effects of nonbuffering ionic species in ion exchange.

Optimization of capacity

When optimum resolution has been achieved, the effect of increasing sample load on resolution should be evaluated to determine the optimal balance of resolution and capacity utilization. The procedure for determining the dynamic (column) capacity is described in Support Protocol 3 and can be performed using the conditions for optimal resolution (as determined above) to elute the target protein. Once the capacity is determined under the optimal elution conditions, the effect of changes in sample load on resolution can be investigated to identify optimal conditions. It is generally recommended that only 10% to 20% of the dynamic capacity be used to ensure high recoveries of the target protein.

Optimization of throughput

Once optimal conditions for resolution and capacity have been determined, the flow rate in each gradient segment may be increased and the effect on resolution and capacity monitored to complete the optimization process.

Troubleshooting

Common problems encountered during ion-exchange experiments, their potential causes, and suggested solutions are outlined in Table 8.2.5.

Anticipated Results

A chromatogram illustrating typical results of an ion-exchange column chromatography experiment (i.e., Basic Protocol 1) is shown in Figure 8.2.8.

The goal of any purification step is the pure target protein obtained at the end of the day. The chromatogram is only a record for comparison and is deceptive at best. Great care should be exercised in interpreting a chromatogram—i.e., the results from assays performed on fractions collected must be used in interpret-

BOSTON CENTRAL UNIVERSITY LIBRARY

Table 8.2.5 Troubleshooting Guide for Ion-Exchange Chromatography

Problem	Possible cause	Solution
Protein does not elute in the salt gradient	Buffer pH is incorrect	Use buffer pH closer to pI of the protein
	Salt concentration is too low	Use more concentrated elution buffer
Protein does not elute in pH gradient	Buffer pH is incorrect	Calibrate pH meter and prepare new solutions
Protein elutes in wash phase	Salt concentration of binding buffer is too high	Decrease salt concentration of binding buffer
	Salt concentration of sample is too high or pH is wrong	Perform buffer exchange on sample
	Column is not properly equilibrated	Repeat or prolong equilibration until conductivity is constant
	Ionic detergents or other additives are absorbed to column	Clean column
Resolution is less than expected	Gradient slope is too steep	Use shallower gradient or include plateau in gradient
	Flow rate is too high	Run separation at lower flow rate
	Proteins or lipids have precipitated on columns	Clean and regenerate column
	Sample has not been filtered properly before application to the column	Regenerate column, filter sample, and repeat chromatography
	Proteins in sample have formed aggregates that bind strongly to gel	Use urea or detergents to clean column
	Column is poorly packed	Check packing by running a colored compound and observing the band. Repack column if necessary.
	Too much sample mass has been loaded onto column	Clean and regenerate column. Decrease sample load and repeat run.
	Detector flow cell volume or mixing spaces in or after column are too large	Change flow cell or reduce all post-column volumes
Leading or very rounded peaks observed in chromatogram	Column is overloaded	Decrease sample load and repeat run
	Column is poorly packed	Check packing by running a colored compound and observing the band. Repack column if necessary.
	Column needs regeneration	Clean and regenerate column. If this does not help, replace with new one.
Tailing of peak is observed in the chromatogram	Sample is too viscous	Reduce amount of protein, or remove nucleic acids from sample.
	Precipitation of protein has occurred in column filter and/or at top of the gel bed	Clean column; exchange or clean filter.
	Column is poorly packed	Check packing by running a colored compound and observing band. Repack column if necessary.
Previous elution profile cannot be reproduced	Buffer pH and/or ionic strength are incorrect	Prepare new solutions
	Sample has deteriorated during storage	Prepare fresh sample
	Proteins or lipids have precipitated on column	Clean and regenerate column

continued

ECU IASI / CENTRAL UNIVERSITY LIBRARY

Table 8.2.5 Troubleshooting Guide for Ion-Exchange Chromatography, continued

Problem	Possible cause	Solution
	Sample has not been filtered properly	Regenerate column, filter sample carefully, and repeat step
	Equilibration was incomplete	Repeat or prolong equilibration until conductivity is constant
Recovery of activity is low but recovery of protein is normal	Target protein is not stable in the elution buffer and is therefore inactivated	Change elution conditions
	Enzyme separated from cofactor or other substance needed for activity	Test by pooling all fractions and repeating assay
	Microbial growth has occurred in the column	Clean column and store gel in 20% ethanol or other antimicrobial agent[a]
Amount of protein in the eluted fractions is much less than expected	Protein was degraded by proteinases	Add proteinase inhibitors to buffers
	Protein adsorbed to filter during sample preparation	Use another type of filter or add detergents to buffer
	Microbial growth occurred in the column	Clean column and store gel in 20% ethanol or other antimicrobial agent[a]

[a]Microbial growth rarely occurs in columns during use, but steps should always be taken to prevent infection of packed columns, buffers, and gel suspensions; see Support Protocol 5.

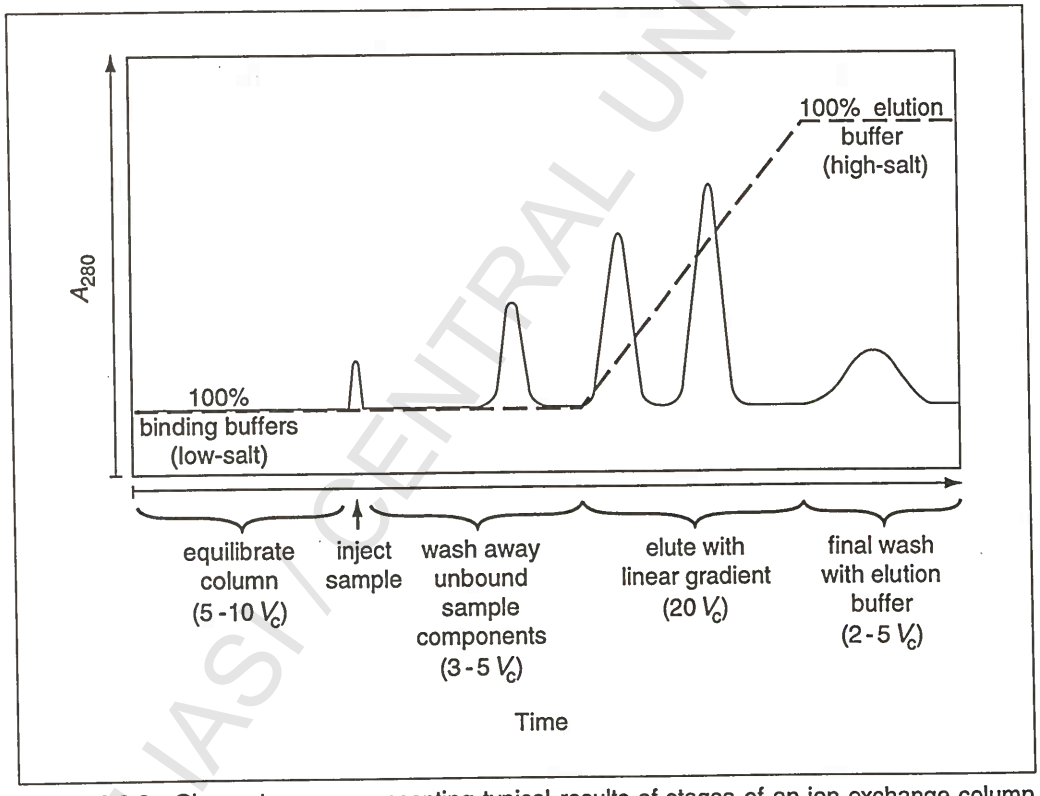

Figure 8.2.8 Chromatogram representing typical results of stages of an ion-exchange column chromatography experiment. A linear gradient of 0% to 100% elution buffer is used as in Basic Protocol 2. The broken line superimposed on the chromatogram represents the composition of the elution gradient (100% binding buffer to equilibrate column and remove unbound sample components, followed by a linear gradient from 100% binding buffer to 100% elution buffer to elute bound proteins and a final wash with 100% elution buffer). V_c represents the packed bed volume of the column.

EAST CENTRAL UNIVERSITY LIBRARY

ing the chromatogram and inferring the identity of any given chromatographic peak.

Time Considerations

If all necessary equipment is available and functioning properly, it should be possible to develop a chromatographic method in a day. With automated systems (e.g., FPLC and HPLC) and modern ion-exchange media, method development may require just a few hours. However, the most time-consuming aspect in developing a purification step is typically the determination of protein purity in the fractions collected, which will always depend on the specific protein of interest. The key to minimizing the time required for such determinations is to strive for high resolution and a minimum number of fractions.

Enzymatic Approaches for Obtaining Amino Acid Sequence: On-Target Ladder Sequencing

Peptide sequencing by mass spectrometry (MS) is usually based on detecting mass differences associated with various amino acids in the polymer chain. Post-source decay (PSD) and MS/MS spectra may yield internal peptide sequences. However, determination of the order of the first two, and sometimes the last few, amino acids in the peptide is often problematic without additional experiments. Several enzymatic approaches have proven useful for identifying the N- and C-terminal residues (Patterson et al., 1995; Thiede et al., 1995; Woods et al., 1995). They involve the use of carboxypeptidases and aminopeptidases to produce peptide ladders for rapid analysis by matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS).

The ladder sequence method described in the Basic Protocol may generate sequence information from low- to subpicomole quantities of peptides and can be performed directly on the sample stage, thus minimizing potential sample losses to vials and through sample transfer. It should be pointed out that success is not predictable because of the substrate specificity of the enzymes. However, the experiments are easy to perform and the resulting mass spectra easy to interpret.

BASIC PROTOCOL

Materials

Carboxypeptidase P, Y, and A
50 mM sodium citrate buffer, pH 6.0
Aminopeptidase M
50 mM ammonium carbonate buffer, pH 7.0
~1 pmol/µl peptide substrate in 0.1% (v/v) trifluoroacetic acid (TFA)
Matrix solution (*UNIT 16.3*, Basic Protocol 1)
10% (v/v) formic acid, cold
Matrix-assisted laser desorption/ionization (MALDI) mass spectrometer

1. Prepare C-terminal sequencing enzyme in sequencing buffer immediately before use:

   0.1 to 0.2 µg/µl carboxypeptidase P in 50 mM sodium citrate buffer, pH 6.0
   0.1 to 0.2 µg/µl carboxypeptidase Y in 50 mM sodium citrate buffer, pH 6.0
   0.1 to 0.2 µg/µl carboxypeptidase A in 50 mM sodium citrate buffer, pH 6.0.

   Carboxypeptidases have different preferences for each amino acid, causing the kinetics of enzymatic release of different amino acids to vary considerably. Therefore, it is advisable to use different carboxypeptidases in parallel in a time-monitored fashion to release all amino acids in an interpretable manner.

   When the amount of sample is limited and C-terminal sequence information is needed, start with carboxypeptidase Y (as this enzyme can cleave all C-terminal residues) or use a mixture of all three enzymes.

2. Prepare N-terminal sequencing enzyme in sequencing buffer immediately before use:

   2.0 µg/µl aminopeptidase M in 50 mM ammonium carbonate buffer, pH 7.0

BCU IASI CENTRAL UNIVERSITY LIBRARY

3. Apply 0.3 µl of ~1 pmol/µl peptide substrate in 0.1% TFA to a clean sample target for each time point and enzyme to be used. Add an equal volume of sequencing enzyme to each.

   At relatively high peptide concentrations (≥1 pmol/µl) the incubation may also be performed in a microcentrifuge tube from which aliquots are subsequently taken and applied to the target at different time points.

   For six time points and four enzymes, a total of twenty-four spots is needed.

4. Incubate sample target for 9, 15, 30, 60, 90, and 600 sec at room temperature.

   Lower concentrations of substrate generally require shorter incubation periods with enzymes to sequentially cleave the same number of residues from both the C- and N-terminal ends. The above time points are suitable for ~1 pmol/µl of peptide substrate.

   It is advisable to perform the digestion time course in a humidified chamber, as spots of the longer incubations may dry up.

5. To end the digestion, add 0.6 µl matrix solution to the digest mixture, mix by pipetting up and down, and allow to air dry.

6. Rinse the matrix/sample preparations with 10 µl cold 10% formic acid (*UNIT 16.3*, Basic Protocol 2, step 4).

7. Insert the sample target into the mass spectrometer and perform mass analysis according to the instrument manufacturer's instructions (*UNIT 16.3*, Basic Protocol 1).

COMMENTARY

Background Information

Enzymatic sequencing is an alternative approach to chemical sequencing or fragmentation induced in the mass spectrometer. Carboxypeptidases offer a simple method by which amino acids can be sequentially cleaved from the C terminus of a protein or a peptide. Carboxypeptidase Y is a particularly attractive enzyme as it nonspecifically cleaves all residues from the C terminus, proline included. Aminopeptidase M is a metalloprotease completely hydrolyzing peptides and proteins with a free α amino group and L amino acids (X-Pro bonds are not cleaved). Enzymatic sequencing was historically performed by analysis of the released amino acids, which was complicated by amino acid contaminants and required relatively large amounts of sample. Using mass spectrometric techniques such as MALDI-MS, however, it is possible to perform direct mass analysis of the peptide fragments resulting from carboxypeptidase digestion. In this ladder sequencing approach, a sequence can be read, in the correct order, by calculating the differences in mass of adjacent peptide peaks. Enzymatic sequencing has been performed mostly in a time-dependent approach (see Basic Protocol), although concentration-dependent carboxypeptidase digestion has been successfully used for enzymatic sequencing as well (Patterson et al., 1995). Both digestion approaches can be conveniently performed on the MALDI sample target, minimizing the amounts of sample and enzyme consumed and losses of sample to vials.

Critical Parameters

Carboxypeptidase digestions often need to be optimized to obtain the maximum sequence information in the shortest amount of time. For example, when the enzyme concentration is too high, sequence gaps may occur for adjacent amino acids that are readily cleavable. Lower concentrations of enzyme may allow for all amino acids to be sequenced, but often require long periods of time (up to days) for total digestion.

Mass spectrometry cannot differentiate between leucine and isoleucine or between lysine and glutamine because they have identical molecular weight. Moreover, the confidence with which amino acid sequences are determined depends on the instrumental mass accuracy. For MALDI mass analysis without delayed extraction, depending on the amino acids, multiple measurements may be needed for reliable assignments. For example, more analyses are required for mass differences of 113 to 115 Da (Ile/Leu, Asn, and Asp) and 128 to 129 Da (Glu/Lys/Glu) than for mass differences around

ASU LIBRARY ARIZONA STATE UNIVERSITY

163 (Tyr) and 57 (Gly), when excluding all but one assignment as statistically unlikely. See Patterson et al. (1995) for statistical considerations.

Anticipated Results

Using MALDI-MS analysis of on-target carboxypeptidase digestions, peptides of various amino acid composition, size, charge, and polarity have been successfully C-terminally sequenced at low picomole levels (Patterson et al., 1995; Thiede et al., 1995; Woods et al., 1995). Due to the salt content of the enzyme/buffer solution, prominent MNa^+ ions may be detected in addition to MH^+ ions when the carboxypeptidases are used at 0.2 µg/µl.

Time Considerations

The amount of digestion time needed to obtain C-terminal or N-terminal sequence information of a peptide or protein may vary from a few minutes to many hours.

Native Chemical Ligation of Polypeptides

The total synthesis and semisynthesis of proteins allows the site-specific incorporation of unnatural amino acids, post-translational modifications, and biophysical/biochemical probes into the target molecule. Among the various chemical and enzymatic approaches available for the synthesis/semisynthesis of proteins, the native chemical ligation technique has proven especially useful and will be the exclusive focus of this unit. Native chemical ligation allows native backbone proteins to be assembled from fully unprotected polypeptide building blocks. To facilitate the ligation reaction, the α-carboxylate group of the N-terminal polypeptide fragment must be mildly activated as an aryl thioester, while the C-terminal polypeptide fragment must contain an amino-terminal cysteine residue. The reaction is normally carried out in aqueous buffers at around neutral pH and can be performed with complete regioselectivity in the presence of all the functionalities commonly found in proteins. Even the presence of additional cysteine sulfhydryl groups in one or both peptide fragments does not affect the reaction regioselectivity. The unit first discusses how to choose the ligation site(s) in the target protein and then outlines how to obtain the necessary polypeptide building blocks using either chemical synthesis or recombinant DNA expression (see Strategic Planning). Next, the synthesis of a protein by native chemical ligation of two polypeptide fragments is described (see Basic Protocol 1). The synthesis of a protein from three polypeptide fragments using a sequential native chemical ligation strategy is also described (see Basic Protocol 2). The support protocols describe how to obtain the necessary polypeptide fragments using either chemical synthesis or recombinant DNA expression.

NOTE: All the operations involving volatile chemicals should be performed in a well ventilated fume hood. See *APPENDIX 2A* for general safety guidelines.

STRATEGIC PLANNING

The first step in synthesizing a protein by native chemical ligation is to choose the ligation site(s), thereby defining the polypeptide fragments to be used in the ligation reactions. The position of the ligation site depends upon several factors: the primary sequence of the protein; the secondary and tertiary structures of the protein (if known); and the type of strategy being used to generate the fragments, i.e., chemical synthesis or recombinant DNA expression. Ideally the target protein should be divided up into synthetically accessible fragments the size of which depends upon whether chemical synthesis or biosynthesis is being used for their generation; optimized solid-phase peptide synthesis (SPPS; also see *UNIT 18.1*) allows polypeptides of up to ~50 residues to be efficiently prepared, whereas recombinant DNA expression permits the preparation of much larger fragments. For example, a hypothetical 100-amino-acid protein could be assembled either from two ~50-residue synthetic peptides or from a 20-residue synthetic fragment and an 80-residue recombinant fragment. Note that in the latter strategy (i.e., semisynthesis) it is important to design the synthesis in such a way that the chemically synthesized fragment encompasses the region of the protein to be engineered. Where possible, naturally occurring X-Cys motifs in the native sequence should be chosen as the ligation sites, where X can be any residue except Asp, Asn, Glu, Gln, and Pro. In the absence of an endogenous Cys at the appropriate position in the primary sequence, it will be necessary to mutate a native residue in order to facilitate ligation. The effect of this Cys mutation on the structure and function of the protein can usually be minimized by following a few simple rules: (1) If the tertiary structure of the protein is known, choose a region remote from the active site of the protein, preferably in a flexible surface loop; (2) choose the mutation to be as conservative as possible, e.g., Ser→Cys or Ala→Cys; (3) try to avoid

mutating residues that are conserved across a gene family; and (4) take advantage of any known mutational data on the system since the effect on structure/function of mutating a particular residue may already be known.

Chemical synthesis and recombinant DNA expression each allow the generation of polypeptides containing an amino-terminal cysteine residue (C-terminal fragment) and the generation of polypeptides containing an α-thioester functionality (N-terminal fragment). For polypeptides of ~50 residues or less, chemical synthesis is usually the method of choice since it is relatively quick and efficient and allows the incorporation of unnatural amino acids. Amino-terminal cysteine–containing peptides can be chemically synthesized via established *t*-butyloxycarbonyl (Boc) or 9-fluorenyloxycarbonyl (Fmoc) SPPS protocols using commercially available resins (e.g., from NovaBiochem, Bachem, Peptides International, Applied Biosystems, or Neosystems) and amino acid derivatives (see Table 18.4.1). The synthesis of peptide α-thioesters can currently only be achieved using Boc chemistry, due to the sensitivity of the thioester functionality to the base-deprotection conditions associated with the Fmoc-SPPS strategy. Note, the resin required for the synthesis of peptide α-thioesters is not commercial available, but can be prepared in the laboratory in a single day.

For polypeptide fragments larger than ~50 amino acids in length, a biosynthetic strategy should be employed. It must be noted that this assumes the gene has been cloned. Polypeptides containing amino-terminal Cys residues can be obtained using a mutagenesis/proteolysis strategy. This involves constructing an expression vector in which a DNA sequence encoding the peptide Ile-Glu-Gly-Arg-Cys is inserted between a upstream affinity-purification handle (e.g., GST or His tag) and the appropriate gene fragment of interest (for cloning strategies see *UNIT 6.6*). Following expression and affinity purification (*UNIT 6.6*), the fusion protein is treated with Factor Xa to give the desired recombinant Cys-polypeptide. Polypeptides containing α-thioester functionalities can be obtained by expressing the corresponding polypeptide sequence using the IMPACT expression system (New England Biolabs). This results in the generation of a fusion protein in which the polypeptide of interest is attached through its C-terminus to an intein-CBD, where the intein is an engineered protein-splicing element and CBD (chitin binding domain) is an

RSU IASC/CLEFTIN UNIVERSITY LIBRARY

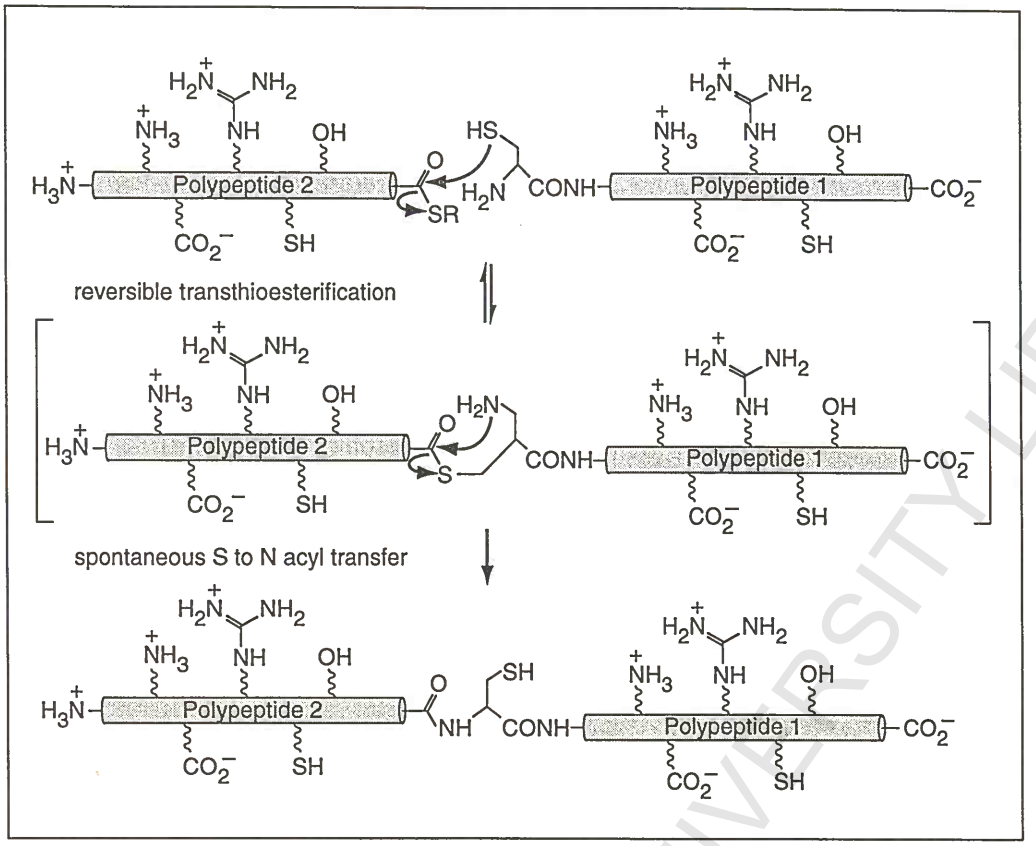

Figure 18.4.1 The mechanism of native chemical ligation. The initial step is a reversible transthioesterification reaction involving the thiol group of the N-terminal Cys-polypeptide (C-terminal fragment) and the α-thioester moiety of the N-terminal polypeptide fragment. This intermediate undergoes a spontaneous rearrangement to form a natural peptide bond at the ligation site.

affinity handle. The desired recombinant α-thioester polypeptide can be obtained by simply treating the immobilized fusion protein with an appropriate thiol; the intein-CBD construct remains attached to the affinity matrix.

NATIVE CHEMICAL LIGATION OF TWO POLYPEPTIDES

BASIC PROTOCOL 1

This protocol describes the chemical ligation of two polypeptide segments to afford a target protein containing both fragments linked through a native peptide bond. The reaction is initiated by dissolving both peptides in aqueous buffer at pH 7.5 in the presence of thiol cofactors. The reaction usually takes between 1 and 3 days to go to completion, at which point the product is purified using reversed-phase high-performance liquid chromatography (RP-HPLC) and subsequently folded. A schematic of the chemistry behind the procedure is presented in Figure 18.4.1.

Materials

6 M guanidine·HCl buffer (see recipe)
Nitrogen source (ultrapure)
Benzyl mercaptan (Aldrich)
Thiophenol (Aldrich)
Polypeptide with N-terminal Cys residue (see Support Protocols 1 and 2)
Polypeptide with α-thioester functionality (see Support Protocols 3 and 4)
1 M NaOH
Tris(2-carboxyethyl)phosphine hydrochloride (TCEP, 99% pure; Strem Chemicals)

continued

BOWLES / SCRIPPS UNIVERSITY LIBRARY

Buffers for analytical C18 reversed-phase HPLC
Buffer A: H_2O containing 0.1% trifluoroacetic acid (TFA)
Buffer B: 1 part H_2O/9 parts acetonitrile/0.1% TFA
Appropriate final buffer in which target protein will be dissolved (e.g., for long-term storage, activity studies, or structural studies), containing 6 M guanidine·HCl and 5 mM DTT
Appropriate final buffer in which target protein will be dissolved, containing 4 M, 2 M, and 0 M guanidine·HCl (*APPENDIX 3A*) and 1 mM DTT

Dialysis membrane with MWCO substantially smaller than target protein
Centricon filter (Amicon; optional)
Tabletop centrifuge (Sorvall RT-7 or equivalent)

Additional reagents and equipment for analytical *and* semipreparative or preparative C18 reversed-phase HPLC, electrospray ionization (ESI) or matrix-assisted laser desorption ionization time-of-flight (MALDI-TOF) mass spectrometry (MS; *UNITS 16.1 & 16.2*), dialysis (*UNIT 4.4 & APPENDIX 3B*), and spectrophotometric determination of protein concentration (*UNIT 3.1*)

Prepare the ligation buffer

1. Degas the 6 M guanidine·HCl buffer by purging with ultrapure nitrogen for at least 20 min.

2. Add benzyl mercaptan and thiophenol, each at a concentration of 0.5% (v/v), to the degassed buffer. Mix by vortexing to produce the ligation buffer.

   IMPORTANT NOTE: *This ligation buffer should be prepared just prior to use and should not be stored for long periods of time. Thiols are, in general, toxic and have an unpleasant odor; therefore thiol-containing solutions should be treated with 5% (v/v) commercial bleach in 1:1 (v/v) methanol/water before being disposed of.*

   Since benzyl mercaptan and thiophenol are barely soluble in aqueous buffers, vortexing is required to form a homogeneous thiol suspension in the ligation buffer.

Ligate the N-terminal and C-terminal polypeptide fragments

3. Dissolve equimolar amounts of the polypeptides to be ligated (i.e., one with an N-terminal Cys residue and the other with an α-thioester functionality) in the ligation buffer to a final concentration of at least 0.5 mM with respect to each peptide.

   Reactions can be run in volumes of 50 to 100 µl for analytical purposes and up to 0.5 to 5 ml for preparative purposes.

   Native chemical ligation reactions are usually carried out in the presence of chaotropic agents (guanidium·HCl or urea) in order to maximize the concentration of the two reactants and to increase the availability of reacting moieties by alleviating any steric hindrance that might be associated with folded polypeptides. The use of chemical denaturants, of course, presumes that the final product can be properly folded in vitro. In cases where the fragments being ligated must be kept in a folded state, the ligation reaction can be carried out in the absence of chemical denaturants.

4. Check the pH of the ligation mixture by spotting a 2- to 3-µl aliquot onto a strip of pH paper. If it is above or below 7.0, adjust the pH by titrating in small increments with 1 M HCl or NaOH, respectively. Repeat this process until a pH of ~7.5 is reached.

   Dissolving lyophilized peptides at high concentrations can cause the pH of the ligation mixture to drop; this is particularly so when HPLC-purified materials are being used (i.e., from acidic conditions). It is extremely important to ensure that the pH of the reaction mixture is kept between 7 and 8, since the efficiency of the native chemical ligation is strongly dependent on the pH. As the pH drops below pH 7.0, the reaction slows down, and as it increases above pH 8.0 the chemoselectivity of the process is lost.

PSU IASL CENTRAL UNIVERSITY LIBRARY

5. Keep the reaction at room temperature with gentle stirring for 24 hr.
6. After 24 hr, take a 5-µl aliquot of the reaction mixture (allowing the rest of the mixture to continue reacting as in step 5) and dilute the aliquot in a polypropylene microcentrifuge tube with 50 µl of 6 M guanidine·HCl buffer in the presence of one crystal of tris-(2-carboxyethyl)phosphine hydrochloride (TCEP, used as a reducing agent). Shake the sample until the TCEP is completely dissolved, wait 10 min, then microcentrifuge 5 min at 10,000 rpm.
7. Analyze 25 µl of the supernatant by analytical C18 reversed-phase HPLC, initially using a linear gradient from 0% buffer B to 73% buffer B over 60 min at a flow rate of 1 ml/min and refining as necessary based on the elution times of the reactants and product. Monitor the run via UV detection at 214 nm (and 280 nm if aromatic residues are present in the target protein). Manually collect every peak (except the solvent peak) into a separate polypropylene microcentrifuge tube and analyze each by ESI-MS (*UNITS 16.1 & 16.2*), which will allow the retention times of the reactants and the product to be determined

   Occasionally the peak corresponding to the ligation product is buried beneath the thiophenol or benzyl mercaptan peaks. This can usually be resolved by optimizing the HPLC gradient or, alternatively, by lyophilizing the reduced sample a few times and then reanalyzing it by HPLC.
8. After 36 hr take another 5-µl aliquot of the reaction mixture and analyze it by HPLC as in step 7. If significant amounts of both reactants still remain and the product peak area is still increasing, then leave the reaction for another 12 hr and repeat the analysis. If, on the contrary, both reactants have been consumed or if the product peak area has not increased appreciably, then terminate the reaction as in step 9.

   Ligation reactions normally take 24 to 36 hr to go to completion, although on rare occasions longer periods (3 to 4 days) or shorter periods (a few hours) may be required.
9. Dilute the crude reaction mixture into 5 to 10 vol of 6 M guanidine·HCl buffer and reduce by adding 15 molar equivalents of TCEP (i.e., based on the quantities of reactants used; 15 times the number of moles of either one of the polypeptides added). Shake the solution until all the TCEP is dissolved and wait for 20 min.
10. Centrifuge the sample 20 min at 3000 rpm in a tabletop centrifuge (Sorvall RT-7 or equivalent), room temperature. Retain the supernatant.

    A white cloudiness often appears in the reaction medium during the course of the reaction. This is due to the slow formation of insoluble benzyl mercaptan and thiophenol disulfides. The reactants and ligation product will generally remain in solution, allowing the unwanted disulfides to be removed by centrifugation.

    The crude ligation mixture can be stored at –80°C for 2 to 3 days, although it is advisable to purify it as soon as possible.

Purify the target protein

11. Purify the crude reaction mixture by semipreparative or preparative reversed-phase HPLC using an optimized gradient system. Analyze each HPLC fraction by mass spectrometry (*UNITS 16.1 & 16.2*) and analytical reversed-phase HPLC in order to identify those fractions containing the target protein. Pool the fractions of highest purity (>95%) and lyophilize.

    Reversed-phase HPLC purification will denature the majority of proteins, meaning that a subsequent refolding step is required. In cases where the ligation reaction has been carried out under more physiological conditions (i.e., without chemical denaturants in the ligation buffer), the final purification step can be performed using, e.g., gel-filtration chromatography (UNIT 8.3) or ion-exchange chromatography (UNIT 8.4) under conditions compatible with protein folding.

BCU MSI CENTRAL UNIVERSITY LIBRARY

Fold the purified protein

12. Dissolve the lyophilized target protein to a final concentration of ≤100 μM in the appropriate freshly degassed buffer (e.g., for long-term storage, activity studies, or structural studies), containing 6 M guanidine·HCl and 5 mM DTT.

    Although the present protocol involves the stepwise dialysis from 6 M guanidium·HCl, it should be stressed that this approach may not work for all proteins and that a certain amount of optimization will be required for every system. It should also be noted that for disulfide-containing proteins, an additional oxidation step will have to be performed.

    In general, the lower the final concentration of protein the better, since this will tend to minimize aggregation during the refolding step.

13. Dialyze the solution at 4°C (*UNIT 4.4 & APPENDIX 3B*) against the same buffer as in step 12, this time containing 1 mM DTT and decreasing amounts of guanidine·HCl (i.e., first against 4 M guanidine·HCl, then against 2 M guanidine·HCl, then against final storage buffer). In each step perform dialysis for at least 12 hr and change the buffer 2 to 3 times during this period.

    The MWCO of the dialysis membrane should be chosen to be substantially smaller than the purified protein.

14. Remove sample from dialysis bag, centrifuge to remove any precipitate, and quantify the supernatant by UV spectrophotometry at 280 nm (*UNIT 3.1*). If necessary concentrate the protein solution using a Centricon filter (*UNIT 4.4*; Amicon), then divide into aliquots and freeze at –70°C.

BASIC PROTOCOL 2

SEQUENTIAL CHEMICAL LIGATION OF THREE POLYPEPTIDES

If the region of interest in the protein is >50 residues from the N- or C-termini, then its chemical modification will be extremely difficult using a two-fragment ligation strategy, since this would require the chemical synthesis of a peptide >50 residues in length. This problem can be overcome by assembling the target protein from three polypeptide fragments using a sequential native ligation strategy. The basic method for sequential native ligation uses a N-terminal Cys polypeptide (C-terminal fragment), an α-thioester polypeptide (N-terminal fragment), and an N^{α}(methylsulfony)ethyloxycarbonyl-Cys, α-thioester polypeptide (central fragment). The procedure starts by ligating the middle fragment and the C-terminal fragment at pH 7.5 in the presence of thiol cofactors. The N^{α}(methylsulfony)ethyloxycarbonyl (Msc) group is then removed and the resulting polypeptide (central plus C-terminal fragment) is ligated with the N-terminal fragment to give the target protein, which is purified and refolded. The general approach is depicted in Figure 18.4.2.

Materials

Three polypeptide fragments to be ligated:
  Polypeptide with N-terminal Cys residue (see Support Protocols 1 and 2)
  Polypeptide with N^{α}(Msc)-Cys, α-thioester functionality (see Support Protocol 5)
  Polypeptide with α-thioester functionality (see Support Protocols 3 and 4)
1 M HCl

Additional reagents and equipment for native chemical ligation of two polypeptides (see Basic Protocol 1)

1. Prepare the ligation buffer (see Basic Protocol 1, steps 1 and 2). Ligate the central [i.e., N^{α}(Msc)-Cys, α-thioester] and C-terminal (N-terminal Cys) polypeptide fragments [see Basic Protocol 1, steps 3 to 8, but use the N^{α}(Msc)-Cys, α-thioester polypeptide in the reaction mix in place of the α-thioester polypeptide].

ESU IASI CENTRAL UNIVERSITY LIBRARY

2. When the ligation reaction is complete, remove the N^{α}-Msc protecting group by raising the pH of the crude ligation mixture to 13 with 1 M NaOH solution (see Basic Protocol 1, step 4). After 1 min, lower the pH to 5.0 to 7.0 with 1 M HCl (use ~1.1 to 1.2 times the volume of 1 M NaOH required to raise the pH to 13).

   Usually, for a 1-ml ligation mixture, the pH can be raised by adding 75 µl of 1 M NaOH, then dropped by adding 95 µl of 1 M HCl. It is recommended that the pH be dropped by adding the acid all at once, instead of by titration, for reasons of speed.

   The presence of thiols improves the yield in the deprotection step, since they trap the still reactive methyl ethylenyl sulfone side product.

3. Analyze the crude reaction mixture (see Basic Protocol 1, steps 6 and 7) and examine to see if the Msc deprotection is complete. Purify the polypeptide fragment (see Basic Protocol 1, steps 9 to 11), which will consist of the central fragment ligated to the C-terminal fragment.

4. Starting with the lyophilized (central plus C-terminal) polypeptide fragment prepared in steps 1 to 3 above and the N-terminal polypeptide fragment (containing an α-thioester functionality), perform the ligation reaction to generate the target protein (see Basic Protocol 1, steps 3 to 10).

5. Purify and refold the target protein (see Basic Protocol 1, steps 11 to 15).

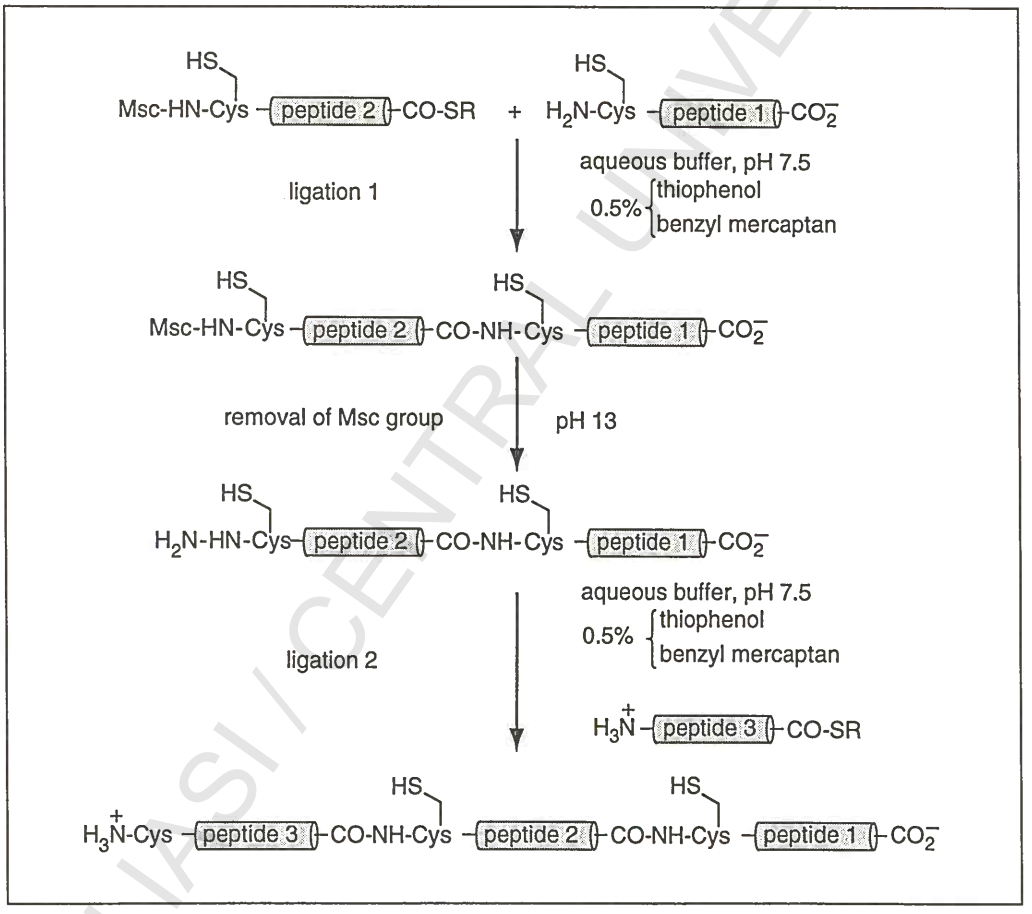

Figure 18.4.2 The principle of sequential native chemical ligation. The key to this approach is the reversible protection of the α-amino group of the central peptide fragment, thereby preventing self-reaction with the α-thioester moiety present in the same molecule. This can be accomplished with the base-labile Msc [N^{α}(methylsulfony)ethyloxycarbonyl] group, which can be easily removed by brief treatment with base after the first ligation step. The newly deprotected fragment is now ready for the next ligation step.

BIBLIASI / CENTRAL UNIVERSITY LIBRARY

SUPPORT PROTOCOL 1

CHEMICAL SYNTHESIS OF N-TERMINAL CYS-POLYPEPTIDES

The chemical synthesis of N-terminal Cys-polypeptides can be easily carried out using standard SPPS with Boc or Fmoc N^{α}-protected amino acids and the appropriate resins (see Table 18.4.1 and *UNIT 18.1*). In both cases, the synthesis can be performed on automated solid-phase peptide synthesizers, which are available in the core facilities of many institutions.

NOTE: Extreme care must be taken to avoid exposing N-terminal Cys-polypeptides to even trace amounts of carbonyl-containing compounds (e.g., acetone or formaldehyde). These chemicals react rapidly with the α-amino and thiol groups of the N-terminal Cys to give a very stable thiazolidine derivative which prevents the peptide from participating in subsequent native chemical ligation reactions. For the same reason, the groups benzyloxymethyl (Bom) and *t*-butyloxymethyl (Bum), used to protect the side-chain of His in Boc and Fmoc SPPS, respectively, should be avoided during the synthesis of these polypeptides since they release formaldehyde during the cleavage/deprotection step.

SUPPORT PROTOCOL 2

BIOSYNTHESIS OF N-TERMINAL CYS POLYPEPTIDES

Biosynthesis represents a complementary approach to chemical synthesis (see Support Protocol 1) for obtaining N-terminal-Cys polypeptides, and is especially useful when the target polypeptide fragment is somewhat greater than 50 residues in length (i.e., too large to be chemically synthesized). Assuming that the cDNA for the gene is available, N-terminal Cys polypeptides can be obtained using a mutagenesis/proteolysis strategy (Erlandson et al., 1996). This involves constructing an expression vector in which a DNA sequence encoding the peptide Ile-Glu-Gly-Arg-Cys is inserted between a upstream affinity-purification handle (e.g., MBP, GST, or His tag) and the appropriate gene fragment of interest (for cloning and mutagenesis see *UNIT 6.6*). Following expression and affinity purification, the fusion protein is treated with Factor Xa to give the desired recombinant Cys-polypeptide, which can then be further purified if necessary. These recombinant Cys-polypeptides can be used in native chemical ligation reactions as per their synthetic counterparts.

SUPPORT PROTOCOL 3

CHEMICAL SYNTHESIS OF α-THIOESTER POLYPEPTIDES

This protocol describes the chemical synthesis of a 3-mercaptopropionamide α-thioester polypeptide on a 3-mercaptopropionamide-MBHA resin. This resin can be easily prepared from commercially available MBHA resin using a three-step solid-phase procedure (Fig. 18.4.3). The solid-phase synthesis of the polypeptide is achieved using Boc amino acid derivatives employing in situ neutralization/HBTU [2-(1H-benzotriazolyl)-1,1,3,3-tetramethyluronium hexafluorophosphate] activation protocols for Boc-SPPS (Schnölzer et al., 1992). The corresponding α-thioester polypeptide, suitable for native chemical ligation, is obtained after cleavage with hydrogen fluoride and purification.

Materials

Methylbenzhydrylamine (MBHA) resin (Peptides International)
Dimethylformamide (DMF, spectrophotometric grade; Fisher)
5% (v/v) diisopropylethylamine (DIEA, peptide synthesis grade; Perkin-Elmer Applied Biosystems) in DMF (store up to 1 month at room temperature)
97% 3-bromopropionic acid
Dichloromethane (DCM, spectrophotometric grade; Fisher)
99% diisopropyl carbodiimide (DIPC, 99%; Aldrich)
Diisopropylethylamine (DIEA, peptide synthesis grade; Perkin-Elmer Applied Biosystems)

continued

10% to 50% acetonitrile in H_2O containing 0.1% TFA

15-ml manual peptide synthesis vessel (Peptides International)
Black rubber tubing (1/4 in. i.d. × 5/8 in. o.d. × 3/16 in. wall thickness; Fisher), resistant to acids and organic solvents
2-liter side-arm flasks with rubber stoppers and glass tubing to fit
Pasteur pipet containing glass wool for filtration
2-ml polypropylene column (Microcolumn X from Isolab) with Teflon stopcock
13 × 100–mm glass test tube
110°C heating block
60% ethanol
HF cleavage apparatus (Peptides International)

Additional material and equipment for solid-phase peptide synthesis (Schnölzer et al., 1992; *UNIT 18.1*), preparative C18 reversed-phase HPLC (see Basic Protocol 1, step 11), and ESI-MS (Chapter 16)

Prepare the MBHA resin

1. Build a manual solid-phase peptide synthesis system (Fig. 18.4.4) consisting of a 15-ml manual peptide synthesis vessel attached by 12 in. of black rubber tubing through a rubber stopper to a 2-liter side-arm flask, which is in turn connected to a vacuum source.

B. C. U. „M. EMINESCU" IAŞI
CHIMIE

BCU IAŞI / CENTRAL UNIVERSITY LIBRARY

2. Place 1 g of MBHA resin (1.0 mmol/g) into the peptide synthesis vessel, add enough DMF to cover the dry resin (~5 ml), and wait 30 min.

This preswelling step is crucial for the success of any reaction carried out on a solid support, since it renders the functional groups on the polymer available for reaction.

3. Drain the resin. Cover the resin with 5% DIEA/DMF, leave for 1 min, then drain the resin. Repeat this process two more times, then perform three 20-sec flow washes with DMF—i.e., wash the resin with a continuous flow of DMF for 20 sec while keeping a constant volume of solvent above the resin bed (usually 3 to 4 mm), then drain the resin.

A continuous flow wash is an extremely efficient way of exchanging solvent in a swollen polymer—much more so than the commonly used bulk wash (i.e., by adding solvent, mixing, and draining).

Prepare the symmetrical anhydride of 3-bromopropionic acid

4. Dissolve 1.222 g 3-bromopropionic acid (8 mmol) in a minimal volume of DCM (~1 to 2 ml), then add 630 µl of 99% DIPC (4 mmol). Shake the solution vigorously and wait 10 min.

A white precipitate corresponding to the diisopropyl urea will appear during the activation reaction. If no such precipitate forms, the reaction has not taken place and should be repeated.

It is best to prepare the symmetrical anhydride fresh for each coupling reaction.

5. Filter the solution through a Pasteur pipet containing glass wool.

It is very important to remove the diisopropyl urea by filtration before adding the symmetrical anhydride solution to the resin. The authors have found that if this step is not carried out the acylation reaction does not go to completion.

Couple the symmetrical anhydride of 3-bromopropionic acid to the MBHA resin

6. Add the filtered solution from step 5 to the MBHA resin in the peptide synthesis vessel. Without applying any suction, add 800 µl DIEA (4.5 mmol) and the minimal amount of DMF (1 to 2 ml) required to give a good slurry.

7. Leave the coupling reaction for 30 min with occasional stirring using a glass stirring rod.

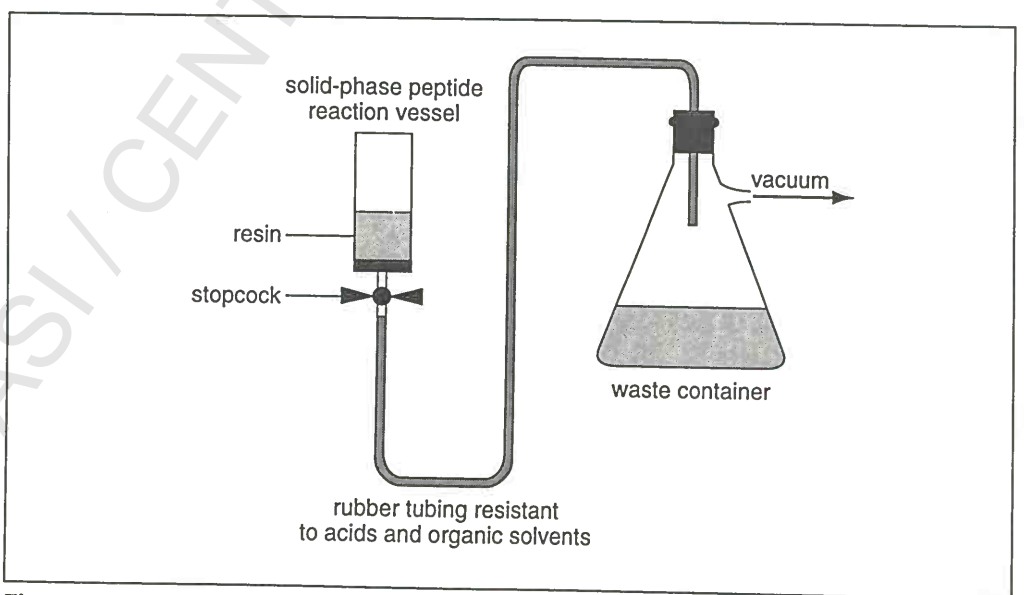

Figure 18.4.4 Suggested apparatus for the manual solid-phase synthesis of thioester peptides.

ASU IASI / CENTRAL UNIVERSITY LIBRARY

8. Drain the resin and wash thoroughly with three 20-sec DMF flow washes as in step 3.

9. Repeat the coupling process (steps 4 to 8) two more times.

10. Add 5 ml Ac_2O/DIEA/DMF solution to the resin and wait 10 min. Drain the resin and wash three times with DMF as in step 3.

This acetylation step ensures that the small amount of unreacted amine groups remaining on the MBHA resin cannot participate in any subsequent acylation steps.

Prepare the 3-mercaptopropionamide-MBHA resin

11. Add 5 ml AcSH/DIEA/DMF solution to the resin and wait 20 min. Drain the resin and wash three times with DMF as in step 3. Repeat this entire process (treatment with AcSH/DIEA/DMF solution, along with the washings) two more times.

12. Add 5 ml BME/DIEA/DMF solution to the resin and wait 20 min. Drain the resin and wash three times with DMF as in step 3. Repeat this entire process (treatment with BME/DIEA/DMF solution, along with the washings) two more times.

The 3-mercaptopropionamide-MBHA resin which is the product of this step is susceptible to oxidation upon long-term storage. The authors therefore recommend that it be immediately acylated with the appropriate Boc amino acid derivative.

Couple the first Boc amino acid to the 3-mercaptopropionamide-MBHA resin

13. Dissolve 3 molar equivalents of the appropriate Boc-AA-OSu (where AA is the first amino acid to be incorporated in the synthesis) in ~6 ml DMF, then add this solution to the 3-mercaptopropionamide-MBHA resin. Add 714 µl DIEA (4 molar equivalents, 4 mmol) and leave the coupling reaction for 3 to 4 hr with occasional stirring.

Most of the Boc amino acid derivatives are commercially available as N-hydroxysuccinimide esters. If the required Boc amino acid derivative is not commercially available it can be readily prepared manually (Bodanszky and Bodanszky, 1994).

14. Drain the resin and wash three times with DMF as in step 3. Add 5 ml Ac_2O/DIEA/DMF solution to the resin and wait 10 min, then wash the resin three times with dichloromethane (DCM) using 20-sec flow washes as described in step 3. Dry the resin under vacuum and store at –20°C.

Determine the final substitution of the Boc-amino acyl-3-mercaptopropionamide-MBHA resin

15. Place ~5 mg of the dry Boc–amino acyl–3-mercaptopropionamide–MBHA resin from step 14 in a 2-ml polypropylene Microcolumn X column with a Teflon stopcock, connected to a vacuum source.

16. Add 1 ml TFA to the resin and wait 2 min. Drain the column, then flow wash first with DMF and then with DCM. Drain again and dry under vacuum.

17. Weigh an exact amount of the dried resin (~3 to 5 mg) and place in a 13 × 100–mm glass test tube.

18. Add 2 drops of ninhydrin test monitor 1 reagent, 4 drops of ninhydrin test monitor 2 reagent, and 2 drops of ninhydrin test monitor 3 reagent, then incubate 5 min at 110°C in a heating block.

19. Dilute the blue solution with 60% ethanol to 25 ml and mix well. Measure the absorbance at 570 nm using 1-cm path-length cuvette. Calculate the substitution of the thioester resin (in mmol/g) as $1.67 \times (A_{570}$/amount of resin in mg).

BOUMAS CENTRAL UNIVERSITY LIBRARY

For a resin with an initial loading of ~1 mmol/g the final substitution for the corresponding acylated thioester resin is usually ~0.2 mmol/g.

Perform solid-phase synthesis of the α-thioester polypeptide

20. Synthesize the polypeptide sequence using the in situ neutralization/HBTU activation protocols for Boc-SPPS (Schnölzer et al., 1992; *UNIT 18.1*).

    Solid-phase deprotection of the 2,6-dinitrophenyl (Dnp) and formyl (For) protecting groups (commonly used for the protection of the side chains of His and Trp residues, respectively) results in premature cleavage of α-thioester polypeptides from the resin. Therefore, these residues should either be deprotected after the ligation reaction is complete or incorporated as Boc-Trp-OH (no side-chain protection) or Boc-Trp(Hoc)-OH and Boc-His(Bom)-OH during SPPS.

21. Once the synthesis is complete, flow wash with DMF and DCM as in step 14. Dry the resin under vacuum and store at –20°C.

Cleave and purify the α-thioester polypeptide

22. Using 200 mg of peptide α-thioester resin from step 21, cleave the peptide-resin by treating with 5 ml of HF:*p*-cresol solution for 1 hr at 4°C in an HF cleavage apparatus.

    CAUTION: *Anhydrous HF is a highly toxic and corrosive gas and should only be manipulated in a fume hood using the commercially available specialized apparatus.*

23. Remove the HF under vacuum and resuspend both peptide and resin in ~40 ml cold diethyl ether with gentle stirring for 10 min. Filter the suspension on a glass Buchner funnel under vacuum, without letting air pass through the filter, as this could oxidize the cleaved peptide.

24. Wash the material in the filter (containing the cleaved peptide and the resin) three times, each time with 10 ml cold diethyl ether. Wash an additional three times, each time with 10 ml dichloromethane, then wash with 10 ml cold diethyl ether again. Discard the wash liquid.

    These washes will remove most of the scavenger byproducts.

25. Add 10 ml freshly degassed 50% acetonitrile in water containing 0.1% TFA to the filter, wait 10 min (to dissolve the cleaved peptide), then filter. Repeat this process three more times, then recover and lyophilize the filtrates.

26. Analyze a 50-µl aliquot by reversed-phase HPLC and ESI-MS (Chapter 16; also see Basic Protocol 1, step 7).

27. Purify the lyophilized propionamide α-thioester peptide by preparative C18 RP-HPLC (see Basic Protocol 1, step 11).

SUPPORT PROTOCOL 4

BACTERIAL EXPRESSION OF α-THIOESTER POLYPEPTIDES

This protocol describes the preparation of α-thioester polypeptides using bacterial expression in *E. coli*. The desired polypeptide-encoding gene fragment is first cloned into a commercially available pTYB vector (Fig. 18.4.5). Following *E. coli* transformation, soluble expression of the polypeptide-intein-CBD (chitin binding domain) fusion protein is induced and the cells are harvested and lysed. The lysate is then loaded onto a chitin column and the fusion protein affinity purified. Finally, the target α-thioester polypeptide is cleaved from the column and eluted using a buffer containing ethanethiol.

NOTE: Initial studies using an MBP-intein-CBD system indicate that the majority of amino acid residues, when located immediately before the intein N-terminal cysteine, allow both purification of fusion proteins and efficient cleavage with thiols. However, Pro,

Figure 18.4.5 pTYB1, one of the series of pTYB vectors useful for the cloning, expression and purification of recombinant α-thioesters polypeptides. (**A**) pTYB1 vector; (**B**) sequence of pTYB1 cloning/expression region. This vector uses a bacteriophage T7 promoter-driven system (see *UNIT 5.1* and Ausubel et al., 1999). The target gene is cloned into the multiple cloning site (MCS) polylinker region to create an in-frame fusion between the C-terminus of the target gene and the N-terminus of the gene encoding a modified intein. The DNA encoding a small chitin binding domain (CBD) has been also added to the C-terminus of the intein gene to allow the resulting fusion protein to be purified by affinity chromatography. Following purification, the target α-thioester polypeptide is obtained through a transthioesterification reaction by treating the fusion protein with ethanethiol. The pTYB vectors are available from New England Biolabs.

BOTANY / CENTRAL UNIVERSITY LIBRARY

Cys, and Asn residues were found to inhibit the in vitro cleavage with thiols. Note that partial cleavage during bacterial expression can sometimes be observed in certain systems, resulting in a decrease in the yield of fusion precursors. For example, in the MBP system, Asp, Arg, His, and Glu residues gave rise to in vivo cleavage (>50%).

Materials

Gene construct encoding target polypeptide
pTYB1 vector (New England Biolabs)
E. coli BL21 (or any other suitable *E. coli* strain)
LB medium containing 100 µg/ml ampicillin (*APPENDIX 4A*)
1 M isopropyl-1-thio-β-D-galactopyranoside (IPTG), filter sterilized
Chitin beads slurry: 50% (w/v) suspension of chitin beads (New England Biolabs) in 40% ethanol
Column buffer (see recipe)
Lysis buffer (see recipe)
Cleavage buffer (see recipe)

Refrigerated centrifuge with Beckman JA-10 rotor and centrifuge buckets to hold 1 liter of culture
1.5 × 10–cm glass or polypropylene column
Refrigerated centrifuge with Beckman JA-17 rotor and appropriate centrifuge tubes
Shaker

Additional reagents and equipment for introducing plasmid vectors into bacterial cells (*APPENDIX 4D*), growth of bacteria in liquid medium (*APPENDIX 4A*), lysis of bacterial cells using a French press (*UNIT 6.3*), ESI-MS (*UNITS 16.1 & 16.2*)

Express the fusion protein

1. Insert the gene construct encoding the target polypeptide into the pTYB1 vector (see manufacturer's instruction for vector and Ausubel et al., 1999) so as to express the target protein as an intein-CBD fusion. Introduce the vector into the *E. coli* BL21 cells (see *APPENDIX 4D* and Ausubel et al., 1999). Inoculate 15 ml LB/ampicillin with *E. coli* BL21 containing a pTYB vector expressing the desired protein fusion. Grow overnight with shaking at 37°C (*APPENDIX 4A*).

2. Inoculate 1000 ml LB/ampicillin with 10 ml of the overnight culture and grow with shaking at 37°C to an OD_{600} of 0.5 to 0.6 (*APPENDIX 4A*).

3. Add 1 ml of 1 M IPTG (final concentration of 1 mM) to the culture and continue incubation for 1 to 6 hr at 37°C.

   The optimal induction conditions (i.e., incubation time, temperature, and final IPTG concentration) for soluble expression will depend on the in vivo properties of the overexpressed protein, and should be optimized for every system.

4. Centrifuge the cell culture 10 min at 8700 × *g* (7000 rpm in Beckman JA-10 rotor), 4°C. Discard supernatant. Proceed to step 5 immediately or freeze pellet at –70°C indefinitely.

   If extract preparation is to be be carried out immediately, the chitin column may be prepared during the centrifugation step.

Prepare the affinity column

5. Add ~10 ml of chitin bead slurry to a 1.5 × 10–cm column and allow liquid to drain just to the top of the packed resin bed (~5 ml).

6. Wash the column with 100 ml column buffer at a flow rate of 1 ml/min.

PSU IASI CENTRAL UNIVERSITY LIBRARY

Prepare the cell extract

7. If cell pellet was frozen, (step 4), thaw on ice. Resuspend pellet in 30 ml ice-cold lysis buffer. Lyse cells using a French press (*UNIT 6.3*).

   IMPORTANT NOTE: *From this step on, all procedures should be carried out at 4°C.*

8. Centrifuge lysate for 30 min (or until supernatant is clear) at 25,000 × *g* (14,000 rpm in Beckman JA-17 rotor), 4°C. Decant supernatant into a clean container on ice and discard pellet.

   The supernatant can be frozen and stored at –70°C indefinitely before continuing with the procedure.

   In order to monitor the expression, extraction, and purification steps, it is convenient to take small aliquots at every step and analyze them by SDS-PAGE (UNIT 10.1).

Purify the fusion protein

9. If extract is frozen, thaw on ice. Load onto the chitin column (at a rate no faster than 0.5 ml/min). Collect flowthrough and reapply to column, then repeat this process one more time.

   Chitin beads have a capacity of ~2 mg of CBD-tagged protein per ml packed beads. Therefore, the amount of extract that can be loaded on the column will depend on the amount of soluble fusion protein in the extract.

10. Wash the column with 100 ml column buffer at a flow rate of 1 ml/min. Discard flowthrough. Be sure that all traces of crude extract have been washed off the sides of the column.

Obtain the α-thioester polypeptide

11. Add 5 ml cleavage buffer to the column and gently shake the reaction slurry overnight at room temperature.

12. Drain the beads, then wash with 15 ml cleavage buffer (three times, each time with 5 ml). Pool all of the fractions.

    IMPORTANT NOTE: *Thioesters are susceptible to hydrolysis under alkaline conditions; consequently purification and storage of α-thioester polypeptides should be performed at pH 6.0 or below.*

Analyze and purify the α-thioester polypeptide

13. Analyze a 50-µl aliquot by reversed-phase analytical HPLC and ESI-MS (see *UNITS 16.1 & 16.2*; also see Basic Protocol 1, step 7).

14. Purify the target α-thioester polypeptide by reversed-phase preparative HPLC see Basic Protocol 1, step 11).

CHEMICAL SYNTHESIS OF N^{α}(Msc)-CYS, α-THIOESTER POLYPEPTIDES

SUPPORT PROTOCOL 5

This protocol describes how to introduce the N^{α}(methylsulfony)ethyloxycarbonyl (Msc) protecting group onto the α-amino group of an N-terminal Cys polypeptide synthesized on a 3-mercaptopropionamide-MBHA resin (see Support Protocol 3). The resulting N^{α}(Msc)-Cys, α-thioester polypeptides are used in sequential native chemical ligation reactions (see Basic Protocol 2).

NOTE: Boc-SPPS of α-thioester polypeptides requires the use of the Bom side-chain protecting group for His. The Bom group releases fomaldehyde during its deprotection with HF; however the formation of the thiazolidine adduct with the N-terminal Cys cannot take place due to the presence of the N^{α}Msc group.

BOU IAST / CENTRAL UNIVERSITY LIBRARY

Additional Materials (also see Support Protocol 3)

Fully protected Boc-polypeptide-3-mercaptopropionamide-MBHA resin (see Support Protocol 3, step 21), dried
(Methylsulfonyl)-ethyl 4-nitrophenyl carbonate (Msc-ONp; Fluka)

Prepare the Boc-polypeptide-3-mercaptopropionamide-MBHA resin

1. Place ~0.5 g of fully protected Boc-polypeptide-3-mercaptopropionamide-MBHA resin in a peptide synthesis vessel attached to a vacuum source and swell with DMF (see Support Protocol 3, steps 1 and 2).
2. Deprotect the Boc group by adding ~5 ml of TFA to the resin, waiting 1 min, then draining the resin. Repeat this process one additional time, then drain the resin and perform three 20-sec flow washes with DMF (see Support Protocol 3, step 3).
3. Neutralize the polypeptide-3-mercaptopropionamide-MBHA resin by treating with 5% DIAE/DMF and flow washing with DMF (see Support Protocol 3, step 3).

Introduce the Msc group on the α-amino group of the polypeptide-3-mercapto-propionamide-MBHA resin

4. Dissolve 560 mg (2 mmol) of Msc-ONp in 4 to 5 ml DMF and add this mixture to the peptide thioester resin, then add 340 µl (2 mmol) of DIEA. Leave the coupling reaction for 3 hr, with occasional stirring using a glass stirring rod, then drain the resin and perform three 20-sec flow washes with DMF.
5. Place ~1 mg of resin from step 4, in a column (see Support Protocol 3, step 15). Flow wash first with DMF and then with DCM, drain again, and dry under vacuum. Place the aliquot in a glass test tube and perform the ninhydrin test (see Support Protocol 3, step 18). If the color of the solution is strongly blue, repeat the coupling reaction (step 4) and test again; if not, continue with step 6, below.

   Sometimes the ninhydrin test can give false positives (i.e., strong blue coloration) even although the acylation reaction is complete. This is especially true when the α-amino group is protected with a base-labile group (i.e., Fmoc or Msc). Therefore, if the ninhydrin test is still positive after the third coupling, proceed to step 6.

6. Perform three 20-sec flow washes with DMF and then with DCM. Dry the resin under vacuum and store at –20°C until further use.
7. Cleave and purify 200 mg of peptide-thioester resin (see Support Protocol 3, steps 22 to 26).

REAGENTS AND SOLUTIONS

Use Milli-Q-purified water or equivalent for the preparation of all buffers. For common stock solutions, see APPENDIX 2E; for suppliers, see SUPPLIERS APPENDIX.

Ac_2O/DIEA/DMF solution

15 parts (v/v) 99% acetic anhydride (Ac_2O)
15 parts (v/v) diisopropylethylamine (DIEA, peptide synthesis grade; Perkin-Elmer Applied Biosystems)
70 parts (v/v) dimethylformamide (DMF, spectrophotometric grade; Fisher)
Prepare fresh

AcSH/DIEA/DMF solution

1 part (v/v) 96% thiolacetic acid (AcSH; Fluka)
1 part (v/v) diisopropylethylamine (DIEA, peptide synthesis grade; Perkin-Elmer Applied Biosystems)
8 parts (v/v) dimethylformamide (DMF, spectrophotometric grade; Fisher)
Prepare fresh

ASU IASC CENTRAL UNIVERSITY LIBRARY

BME/DIEA/DMF solution

1 part (v/v) 98% 2-mercaptoethanol (BME)
1 part (v/v) diisopropylethylamine (DIEA, peptide synthesis grade; Perkin-Elmer Applied Biosystems)
8 parts (v/v) dimethylformamide (DMF, spectrophotometric grade; Fisher)
Prepare fresh

Cleavage buffer

0.1 mM EDTA
200 mM sodium phosphate, pH 6.0
250 mM NaCl
3% (v/v) ethanethiol
0.1% (v/v) Triton X-100
Adjust pH to 6.0 with 1 M NaOH or HCl
Store up to 6 months at 4°C

Column buffer

0.1 mM EDTA
20 mM sodium phosphate, pH 7.2
250 mM NaCl
0.1% (v/v) Triton X-100
Adjust pH to 7.2 with 1 M NaOH or HCl
Store up to 6 months at 4°C

Guanidine·HCl buffer, 6 M

6 M guanidine·HCl (*APPENDIX 3A*)
0.1 M sodium phosphate
1 mM EDTA
Adjust pH to 7.5 with 1 M NaOH
Store up to 6 months at room temperature

HF/p-cresol solution

96 parts (v/v) hydrogen fluoride (HF; anhydrous)
4 parts (v/v) *p*-cresol
Prepare fresh

CAUTION: *Anhydrous HF is a highly toxic and corrosive gas and should be manipulated only in a fume hood, using the commercially available specialized apparatus (HF cleavage apparatus from Peptides International).*

Lysis buffer

0.1 mM EDTA
1 mM PMSF
25 mM HEPES, pH 8.0
250 mM NaCl
5% (v/v) glycerol
Adjust pH to 8.0 with 1 M NaOH
Store up to 6 months at 4°C

COMMENTARY

Background Information

The introduction of solid-phase peptide-synthesis (SPPS) by Bruce Merrifield revolutionized the chemical synthesis of peptides (Merrifield, 1963; also see *UNIT 18.1*). Despite the enormous impact of SPPS in the generation and study of small bioactive peptides, it is now clear that the combination of incomplete acylation/deprotection reactions and other well documented side reactions places an intrinsic limit on the size of peptides accessible by efficient stepwise SPPS. Thus, polypeptides of up

BOU IASU / CENTRAL UNIVERSITY LIBRARY

to ~50 residues in length can be prepared by stepwise SPPS with reasonable confidence, but beyond this, the chances of success fall off precipitously. In order to overcome this size limitation, recent years have seen renewed interest in the use of convergent synthetic strategies—i.e., the synthesis of large polypeptides from smaller peptide building blocks which are themselves accessible via the SPPS approach. It should be noted that fragment condensation has a long and illustrious history in the peptide chemistry field; however, there have always been serious problems associated with the manipulation of the fully protected peptides in these classical convergent strategies. Although the use of minimal protection strategies represented a step in the right direction (see Lloyd-Williams et al., 1993 for an extensive review), it was not until the early 1990s that a truly practical way of performing fragment condensations was developed—i.e., chemical ligation (for reviews see Muir, 1995; Wallace, 1995). The original chemical ligation strategies were all based on the premise that an unnatural moiety could be used to covalently join two fully unprotected (and hence water-soluble) polypeptides, each bearing unique and mutually reactive groups. A number of different chemistries have been developed for this purpose, all of which give rise to an unnatural covalent structure at the ligation site (Muir, 1995; Wallace, 1995).

In 1994, a second-generation ligation chemistry was introduced, known as "native chemical ligation," which allows the preparation of proteins with native backbone structures from fully unprotected peptide building blocks (Dawson et al., 1994). This important extension of the chemical ligation concept makes use of the mild acylating power of the α-thioester functionality. The principle of native chemical ligation is depicted in Figure 18.4.1. The first step involves the chemoselective reaction which occurs between the free thiol group of an unprotected N-terminal Cys-polypeptide and a second, unprotected polypeptide containing an α-thioester group. This transthioesterification reaction gives rise to a thioester-linked intermediate which spontaneously rearranges to form a native peptide bond at the ligation site. The target full-length polypeptide is thus obtained without any further manipulation. Native chemical ligation reactions are performed in aqueous buffers at pH 7 to 7.5 in the presence of thiol cofactors. At this pH, the regioselectivity of the reaction is such that the reaction can to be performed in the presence of all the functionalities commonly found in proteins. Even the presence of additional Cys residues in one or both fragments does not affect the regioselectivity of the ligation (Hackeng et al., 1997). Small proteins or protein domains ~100 to 120 amino acids in length can be reliably generated from two peptide building blocks in a single chemical ligation step (for a few examples see Dawson et al., 1994, 1997; Lu et al., 1996; Hackeng et al., 1997; Camarero et al., 1998).

The total chemical synthesis of larger protein targets (>100 residues) via the ligation of just two fragments becomes more and more problematic as the size increases. This is due to the difficulties associated with the direct stepwise SPPS of polypeptide segments bigger than 50 residues. This difficulty can be overcome by performing multiple ligation reactions using three or more synthetic peptides (e.g., Canne et al., 1995). Native chemical ligation has been extended to allow multiple ligation steps to be performed sequentially in a controlled and directed way (Muir et al., 1997; Camarero et al., 1998). The general approach is depicted in Figure 18.4.2. Key to this strategy is the temporary protection of the α-amino group of the central peptide with the base-labile 2-(methylsulfonyl)ethyloxycarbonyl (Msc) group (Tesser and Balvert-Geers, 1975). The presence of this protecting group prevents the N-terminal Cys from reacting in an intramolecular or intermolecular fashion with the α-thioester functionality present in the same polypeptide fragment. Once the first ligation reaction is finished, the N^{α}-Msc group can be efficiently removed, allowing the next ligation step to be performed (Fig. 18.4.2).

The native chemical ligation approach can also be used in the semisynthesis of proteins (Muir et al., 1998; Severinov and Muir, 1998; Erlandson et al., 1996; Evans et al., 1998) from recombinant and synthetic polypeptide fragments. As described above, native chemical ligation of two polypeptides requires that one of the fragments possess an N-terminal Cys and that the other contain an α-thioester moiety. Polypeptides containing an N-terminal cysteine residue for use in litigation can be obtained using standard recombinant DNA expression methods (see Chapter 5). Importantly, biosynthetic methods are also now available for the generation of α-thioester polypeptides (Muir et al., 1998; Severinov and Muir, 1998; Evans et al., 1998). This is made possible using the IMPACT expression system, commercially available from New England Biolabs (Chong

PSU IAS - CENTRAL UNIVERSITY LIBRARY

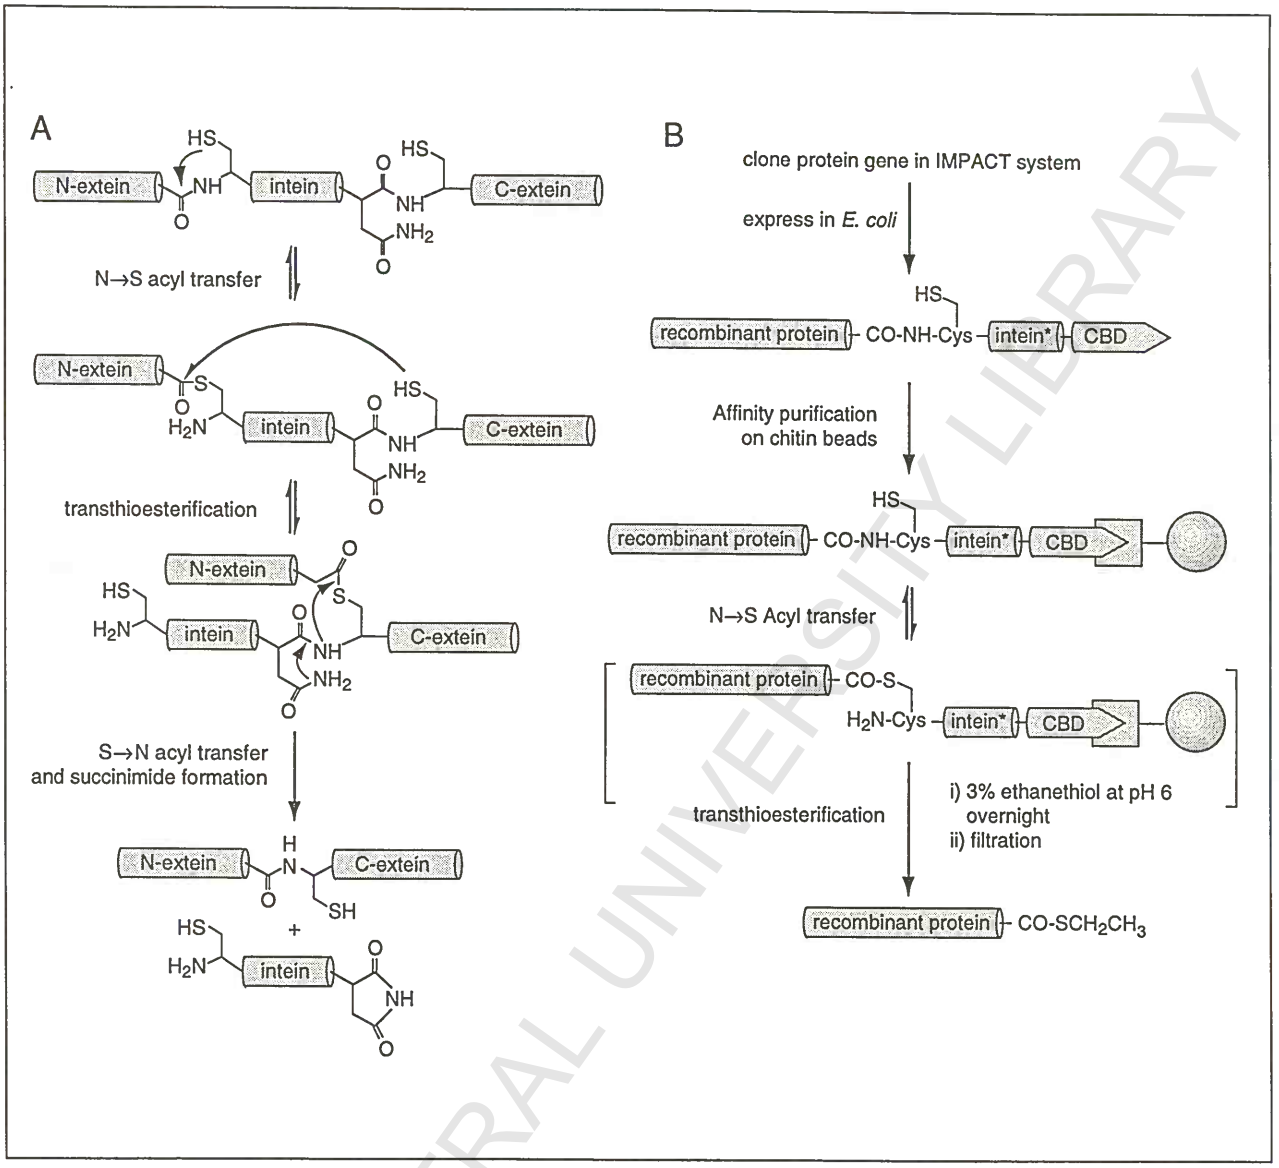

Figure 18.4.6 Principles of the biosynthetic preparation of α-thioester polypeptides by recombinant techniques. (**A**) Scheme representing the proposed mechanism of protein splicing involving the intein from *Saccharomyces cerevisiae* VMA1 gene (Xu and Perler, 1996). (**B**) Expression, purification, and cleavage of polypeptide-intein*-CBD fusion protein (where the asterisk refers to the mutation Asn454→Ala in the intein element and CBD refers to the chitin binding domain) with an appropriate thiol to give the α-thioester polypeptide.

et al., 1997). This system utilizes a protein splicing element, an intein from the *Saccharomyces cerevisiae* VMA1 gene, in conjunction with a chitin binding domain (CBD) which allows purification by affinity chromatography (Fig. 18.4.6). The natural intein has been modified in the expression system (Asn454→Ala) in order to block the normal protein splicing reaction in midstream. This results in the formation of a thioester linkage between the polypeptide of interest and the intein (Fig. 18.4.6). Cleavage of the thioester can thus be induced by treatment of the expressed fusion protein with the appropriate thiol to give the target α-thioester polypeptide (Muir et al., 1998; Severinov and Muir, 1998; Evans et al., 1998).

Critical Parameters and Troubleshooting

As mentioned in Basic Protocol 1, pH is the most critical parameter in the native chemical ligation of two fully unprotected peptides in aqueous buffers. The efficiency of the ligation reaction is strongly dependent on the pH; above pH 8.0 the reaction loses its regioselectivity and below pH 6.0 the reaction is usually very slow.

BOSTON MEDICAL CENTRAL UNIVERSITY LIBRARY

Another crucial factor is the concentration of the two reactants. The bimolecular nature of native chemical ligation (and ligations in general) means that the concentration of both reactants should be as high as possible for efficient reaction. Generally the use of chemical denaturants (GdmCl or urea) will allow high concentrations of both reactants to be achieved. Furthermore, the use of denaturing conditions helps to alleviate potential steric problems that may be associated with the use of folded polypeptides.

Another important parameter for the success of the ligation reaction is the availability of the thiol and/or α-amino groups of the N-terminal Cys polypeptide during the ligation reaction. If one or both groups are chemically blocked, the ligation will not take place. It is well known that N-terminal Cys peptides can react rapidly with carbonyl-containing compounds (e.g., acetone and formaldehyde) to give the corresponding N-terminal thiazolidine adducts, which are totally unreactive in the native ligation process. It is thus crucial to avoid the use of these substances while handling all peptides and buffers. Note that the authors have found acetone, a commonly used solvent for washing glassware in many laboratories, to be particularly problematic in this regard.

Anticipated Results

Native chemical ligation has been applied to the synthesis and semisynthesis of a large number of proteins and protein domains. These studies indicate that very high yields (80% or better) are typically obtained for the ligation step. Following purification, the total yield usually drops to 50% to 60%. In sequential ligations where the N^{α}-Msc group has to be deprotected in situ after the first ligation step, the typical total yield after purification is ~30% to 40%. It is also important to note that the protein-folding step may further decrease the final yield of product.

Time Considerations

In Basic Protocols 1 and 2, the chemical ligation step typically requires 2 days, although in some cases the ligation reaction can proceed very rapidly (in a few hours) or somewhat more slowly (in 4 days). The purification step (RP-HPLC or other liquid chromatographies) can be performed in half a day. Processing of the purified samples (lyophilization or concentration) can take 1 to 2 days (depending on the volume). Finally, folding of the protein (if necessary) can be achieved in 3 days.

The thioester resin can be prepared in 1 day. The time required for the chemical synthesis of an α-thioester polypeptide (see Support Protocol 3) will depend on its size. Typically, for peptides ~50 residues in length, the solid-phase chain assembly can be carried out in 3 days manually or in 1 day using an automated synthesizer. The deprotection-cleavage and purification can be performed in 1 day, and lyophilization of peptide fractions can take 1 to 2 days (depending on the volume).

Bacterial expression of a peptide-intein-CBD fusion protein and preparation of the crude cell extract requires 2 days for the system described here (see Support Protocol 4). Column preparation requires ~2 to 3 hr. Loading and washing the column can be done in 3 hr. The cleavage of the α-thioester polypeptide from the affinity column requires 10 to 15 hr (overnight). Purification and processing of the polypeptide fractions requires 1 to 2 days.

Table 19.2.1 Interaction Trap Components[a,b], continued

Plasmid name/source	Selection		Comment/description
	In yeast	In *E. coli*	
pMW111[f]	*URA3*	Km^r	Same as pRB1840, but with altered antibiotic resistance marker
pMW107[f]	*URA3*	Cm^r	Same as pSH18-34, but with altered antibiotic resistance marker
pMW108[f]	*URA3*	Cm^r	Same as pJK103, but with altered antibiotic resistance marker
pMW110[f]	*URA3*	Cm^r	Same as pRB1840, but with altered antibiotic resistance marker
pJK101[e,f] (control)	*URA3*	Ap^r	Contains a *GAL1* upstream activating sequence followed by two *lexA* operators followed by *lacZ* gene; used in repression assay to assess bait binding to operator sequences

[a]All plasmids contain a 2μm origin for maintenance in yeast, as well as a bacterial origin of replication, except where noted (pEE202I, pJG4.5I).

[b]Interaction Trap reagents represent the work of many contributors: the original basic reagents were developed in the Brent laboratory (Gyuris et al., 1993). Plasmids with altered antibiotic resistance markers (all pMW plasmids) were constructed at Glaxo in Research Triangle Park, N.C. (Watson et al., 1996). Plasmids and strains for specialized applications have been developed by the following individuals: E. Golemis, Fox Chase Cancer Center, Philadelphia, Pa. (pEG202); J. Kamens, BASF, Worcester, Mass. (pJK202); cumulative efforts of I. York, Dana-Farber Cancer Center, Boston, Mass. and M. Sainz and S. Nottwehr, U. Oregon (pNLexA); D.A. Shaywitz, MIT Center for Cancer Research, Cambridge, Mass. (pGilda); R. Buckholz, Glaxo, Research Triangle Park, N.C. (pEE2021, pJG4-51); J. Gyuris, Mitotix, Cambridge, Mass. (pJG4-5); S. Hanes, Wadsworth Institute, Albany, N.Y. (pSH17-4); R.L. Finley, Wayne State University School of Medicine, Detroit, Mich. (pRFHM1); S. Hanes, Wadsworth Institute, Albany, N.Y. (pSH18-34); J. Kamens, BASF, Worcester, Mass. (pJK101, pJK103); R. Brent, The Molecular Sciences Institute, Berkeley, California (pRB1840). Specialized plasmids not yet commercially available can be obtained by contacting the Brent laboratory at (510) 647-0690 or *brent@molsci.org* or the Golemis laboratory, (215) 728-2860 or *EA_Golemis@fccc.edu*.

[c]Sequence data are available for pEG202 (pLexA) accession number pending.

[d]Plasmids commercially available from Clontech and OriGene; for Clontech pEG202 is listed as pLexA, pJG4-5 as pB42AD, and pSH18-34 as p8op-LacZ.

[e]Plasmids and strains available from OriGene.

[f]In pMW plasmids the ampicillin resistance gene (Ap^r) is replaced with the chloramphenicol resistance gene (Cm^r) and the kanamycin resistance gene (Km^r) from pBC SK(+) and pBK-CMV (Stratagene), respectively. The choice between Km^r and Cm^r or Ap^r plasmids is a matter of personal taste; use of basic Ap^r plasmids is described in the basic protocols. Use of the more recently developed reagents would facilitate the purification of library plasmid in later steps by eliminating the need for passage through KC8 bacteria, with substantial saving of time and effort. Ap^r has been maintained as marker of choice for the library plasmid because of the existence of multiple libraries already possessing this marker. These plasmids are the basic set of plasmids recommended for use.

[g]Plasmids commercially available from Invitrogen as components of a Hybrid Hunter kit; this kit also includes all necessary positive and negative controls (not listed in this table). See Background Information for further details on commercially available reagents.

porter—the EGY48 strain (or related strain EGY191) that expresses the LexA fusion protein should not grow on medium lacking Leu, and the colonies should be white on medium containing Xgal. The characterized bait protein plasmid is used for Basic Protocol 2 to screen a library for interacting proteins.

Materials

DNA encoding the protein of interest

Plasmids (see Table 19.2.1): pEG202 (see Fig. 19.2.3), pSH18-34 (see Fig. 19.2.4), pSH17-4, pRFHM1, and pJK101 for basic characterization; other plasmids for specific circumstances as described (Clontech, Invitrogen, OriGene, or R. Brent)

Yeast strain EGY48 (*ura3 trp1 his3 3LexA*-operator-*LEU2*), or EGY191 (*ura3 trp1 his3 1LexA*-operator-*LEU2*; Table 19.2.2)

[a]Most libraries are constructed in either the pJG4-5 vector or the pYESTrp vector (JG or Y in the Vector column); the peptide aptamer library is made in the pJM-1 vector. Libraries available from the public domain were constructed by the following individuals: (1) J. Gyuris; (3) C. Sardet and J. Gyuris; (4) W. Kolanus, J. Gyuris, and B. Seed; (39) D. Krainc; (50-52) R. Finley; (55) P. Watt; (54) P. Colas, B. Cohen, T. Jessen, I. Grishina, J. McCoy, and R. Brent (Colas et al., 1996). All libraries mentioned above were constructed in conjunction with and are available from the laboratory of Roger Brent, (510) 647-0690 or *brent@molsci.org*. The following individual investigators must be contacted directly: (18) J. Pugh, Fox Chase Cancer Center, Philadelphia, Pa.; (8,9) Vinyaka Prasad, Albert Einstein Medical Center New York, N.Y.; (57, 58) Gregory B. Martin, *gmartin@dept.agry.purdue.edu*; (11) Huifeng Niu, *hn34@columbia.edu*; (16) Christer Hoog, *christer.hoog@cmb.ki.se*; (12) Kurt Gustin, *kgus@umich.edu*; (6) Stephan Witte, *Stephan.Witte@nimbus.rz.uni-konstanz.de*.

[b]Insert size ranges for pJG4-5 based libraries originally constructed in the Brent laboratory, which are now commercially available from Clontech, were reestimated by the company.

Transform the library

1. Grow an ~20-ml culture of EGY48 or EGY191 containing a *LexA*-operator-*lacZ* reporter plasmid and pBait in Glu/CM –Ura, –His liquid dropout medium overnight at 30°C.

   For best results, the pBait and lacZ reporter plasmids should have been transformed into the yeast within ~7 to 10 days of commencing a screen.

2. In the morning, dilute culture into 300 ml Glu/CM –Ura, –His liquid dropout medium to 2×10^6 cell/ml (OD_{600} = ~0.10). Incubate at 30°C until the culture contains ~1×10^7 cells/ml (OD_{600} = ~0.50).

3. Centrifuge 5 min at 1000 to 1500 × *g* in a low-speed centrifuge at room temperature to harvest cells. Resuspend in 30 ml sterile water and transfer to 50-ml conical tube.

4. Centrifuge 5 min at 1000 to 1500 × *g*. Decant supernatant and resuspend cells in 1.5 ml TE buffer/0.1 M lithium acetate.

5. Add 1 µg library DNA in pJG4-5 and 50 µg high-quality sheared salmon sperm carrier DNA to each of 30 sterile 1.5-ml microcentrifuge tubes. Add 50 µl of the resuspended yeast solution from step 4 to each tube.

   The total volume of library and salmon sperm DNA added should be <20 µl and preferably <10 µl.

   A typical library transformation will result in 2 to 3 × 10^6 primary transformants. Assuming a transformation efficiency of 10^5/µg library DNA, this transformation requires a total of 20 to 30 µg library DNA and 1 to 2 mg carrier DNA. Doing transformations in small aliquots helps reduce the likelihood of contamination, and for reasons that are not clear, provides significantly better transformation efficiency than scaled-up versions.

   Do not use excess transforming library DNA per aliquot of competent yeast cells because each competent cell may take up multiple library plasmids, complicating subsequent analysis.

BU IASI CENTRAL UNIVERSITY LIBRARY

Phage-Based Expression Cloning to Identify Interacting Proteins

Interaction cloning (also known as expression cloning) is a technique to identify and clone genes which encode proteins that interact with a protein of interest, or "bait" protein. Phage-based interaction cloning requires a gene encoding the bait protein and an appropriate expression library constructed in a bacteriophage expression vector, such as λgt11. The gene encoding the bait protein is used to produce recombinant fusion protein in *E. coli*. The cDNA is radioactively labeled with ^{32}P. A recognition site for cyclic adenosine 3′, 5′-phosphate (cAMP)–dependent protein kinase (protein kinase A; PKA) is introduced into the recombinant fusion protein to allow its enzymatic phosphorylation by PKA and [γ-^{32}P]ATP. The procedure presented here (see Basic Protocol) involves a fusion protein consisting of bait protein and glutathione-*S*-transferase (GST) with a PKA site at the junction between them (the protocol can, however, be adapted to use other PKA-containing recombinant proteins). The labeled protein is subsequently used as a probe to screen a λ bacteriophage-derived cDNA expression library, which expresses β-galactosidase fusion proteins that contain in-frame gene fusions. The phages lyse cells, form plaques, and release fusion proteins that are adsorbed onto nitrocellulose membrane filters. The filters are blocked with excess nonspecific protein to eliminate nonspecific binding and probed with the radiolabeled bait protein (see Fig. 19.3.1). This procedure leads directly to the isolation of genes encoding the interacting protein, bypassing the need for purification and microsequencing or for antibody production.

NOTE: Radioactive label is used in this protocol, and appropriate precautions and shielding should be used (*APPENDIX 2B*).

STRATEGIC PLANNING

There are two important choices one must make to begin this procedure: (1) how to design the bait protein and (2) how to construct or acquire an appropriate phage-derived expression library.

Vectors for recombinant fusion protein expression that contain a PKA recognition site can be obtained commercially. Several companies now sell these vectors with various affinity tags such as GST (Pharmacia Biotech), histidine (Novagen), or calmodulin-binding protein (Stratagene). Alternatively, one can engineer the PKA recognition site (the five–amino acid sequence RRASV) into existing vectors by using synthetic DNA that encodes it.

Lambda-derived expression libraries that direct the expression of cDNAs made from many different mRNA sources are widely available. Alternatively, a library may be constructed for a particular experimental purpose; when designing a library to be used in expression cloning, several points should be considered. Libraries made from cDNA synthesized with random primers or an oligo dT-primer during first-strand synthesis (Klickstein et al., 1995; Klickstein and Neve, 1991) can often be advantageous in that multiple clones representing different portions of the same protein can be identified in the screening. Analysis of coding regions present in these multiple clones could provide useful information about what region of the protein is responsible for the observed interaction. Full-length cDNA clones can subsequently be obtained from other available libraries.

Many suitable λ vectors are available for constructing cDNA expression libraries. The most widely used cDNA expression vector has been λgt11 (Huynh et al., 1985). There are modifications of these λ vectors, however, that facilitate the recovery of the cDNA

BOU INST CENTRAL UNIVERSITY LIBRARY

inserts by avoiding the necessity of time-consuming λ phage DNA preparations. These modified vectors include those that make use of the *Cre-lox* recombination for in vivo conversion of recombinant phages into plasmid DNA in *Cre* recombinase-expressing host strains (e.g., λZipLox, Life Technologies) as well as those that employ helper phage for in vivo excision of a phagemid vector (e.g., the λZAP series of vectors, Stratagene). Most λ vectors available produce fusions of the cDNA inserts to β-galactosidase, because they are cloned into the *lacZ* gene. However, some λ-derived expression vectors (e.g., λSCREEN-1, Novagen) direct expression of proteins fused to the T7 DNA polymerase promoter (gene *10* under control of the T7 promoter) and may yield higher expression of the library proteins (Margolis et al., 1992).

BASIC PROTOCOL

INTERACTION CLONING

Phage-based interaction expression cloning is a simple, rapid, and powerful technique to identify interacting proteins. A protein of interest is expressed as a recombinant fusion protein and labeled with ^{32}P at a serine residue in an engineered PKA recognition site to facilitate detection. β-galactosidase proteins that are fused in-frame to cDNA inserts in a bacteriophage λ-derived expression library are produced by the phage and adsorbed onto nitrocellulose filters. The filters are then screened with the radiolabeled protein probe to identify phage clones that express an interacting protein.

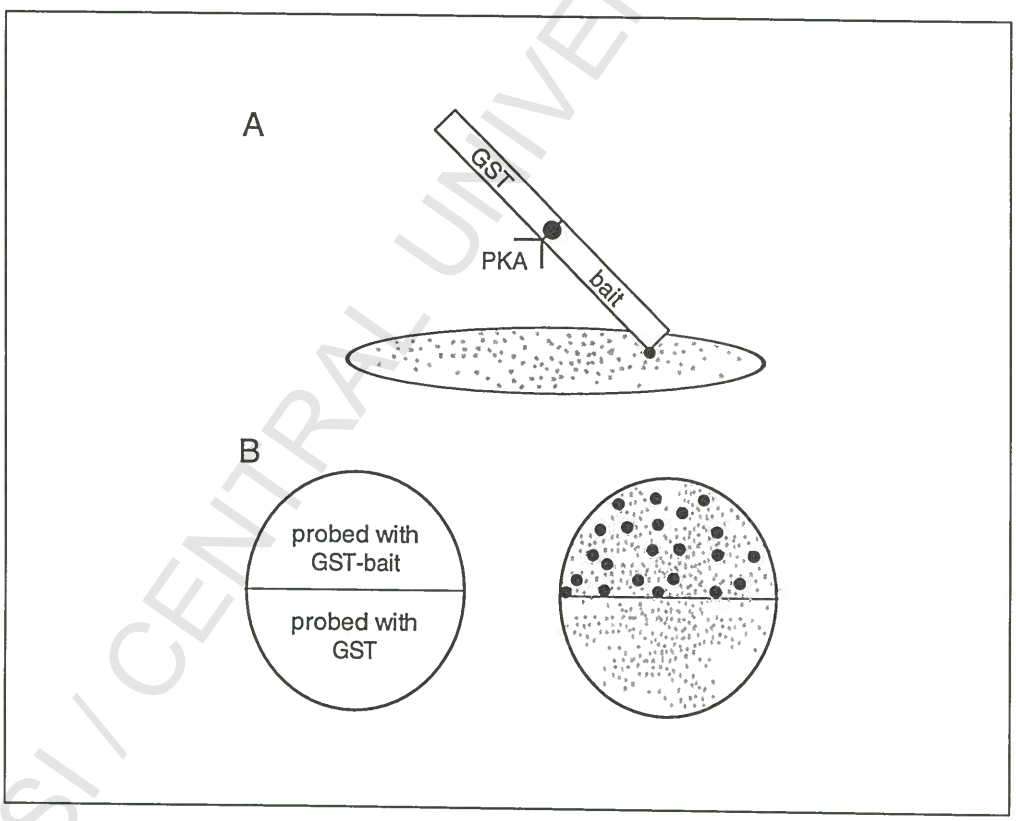

Figure 19.3.1 Schematic representation of the interaction cloning technique used to identify proteins that associate with a protein of interest (bait protein), and the expected results of a successful screen. (**A**) Expression of β-galactosidase fusion proteins from in-frame cDNA inserts of a λgt11 *Arabidopsis* library is induced with IPTG-impregnated nitrocellulose membrane filters (indicated by an oval). Filters are probed with GST-bait fusion protein labeled with ^{32}P (•) at the PKA recognition site located at the junction of the fusion. Interacting clones are detected by autoradiography. (**B**) Representative autoradiogram of a tertiary screen of a positive plaque after the control experiment to determine whether the interaction is specific for the bait portion of the probe. The top half of the filter is probed with GST-bait while the bottom half is probed with GST alone as a control.

RCU IASI / CENTRAL UNIVERSITY LIBRARY

Materials

cAMP-dependent protein kinase (PKA; e.g., 250-U lots from Sigma)
40 mM DTT, prepared fresh
10× PKA buffer (see recipe)
10 mCi/ml [γ-^{32}P]ATP (6000 mCi/mmol)
Purified glutathione-*S*-transferase (GST)–bait protein fusion protein with a PKA recognition site (*UNIT 6.6*), at ~0.1 to 1 µg/µl concentration
Z′-KCl (see recipe), ice cold
Sephadex G-50 equilibrated in Z′-KCl
E. coli Y1090r$^-$ or other appropriate host strain
LB medium containing appropriate selective antibiotic (*APPENDIX 4B*), 10 mM $MgSO_4$, and 0.2% maltose
10 mM $MgSO_4$
10 mM IPTG (Table 1.4.2)
150- or 100-mm LB plates (with antibiotic, if necessary; *APPENDIX 4B*)
0.7% top agarose (*APPENDIX 4B*), 47°C
Tris-buffered saline with Triton X-100 (TBS-T; see recipe)
India ink
HEPES blocking buffer (HBB; see recipe)
Binding buffer (BB; see recipe)
Suspension medium (SM; see recipe)
Chloroform

3-ml disposable plastic columns *or* disposable syringe and glass wool
Scintillation counter
Tabletop centrifuge or equivalent
Nitrocellulose membrane filters (137- and 82-mm disks)
22-G needle

Additional reagents and equipment for preparation and purification of recombinant glutathione-*S*-transferase fusion protein (*UNIT 6.6*), SDS-PAGE (optional; *UNIT 10.1*), autoradiography (*UNIT 10.11*), titering and plating λ phage to generate plaques (Lech and Brent, 1988; Quertermous, 1996), and purification of bacteriophage clones (Quertermous, 1987)

Prepare the ^{32}P-labeled protein probe

1. Resuspend 250 U PKA in 25 µl freshly prepared 40 mM DTT. Let the reconstituted enzyme stand at room temperature ~10 min before use.

   It is important to use freshly prepared 40 mM DTT. PKA is extremely unstable after reconstitution; the enzyme stock solution can be stored temporarily at 4°C but retains activity for only 2 to 3 days.

2. Prepare a phosphorylation reaction mixture containing:

   1 µl 10 U/µl PKA (from step 1)
   3 µl 10× PKA buffer
   5 µl 10 mCi/ml (6000 mCi/mmol) [γ-^{32}P]ATP
   1 to 10 µl (~1 µg) purified GST-bait fusion protein
   H_2O to 30 µl.

   Incubate 1 hr at room temperature.

   A fusion protein unrelated to the bait protein, but containing the PKA recognition site, should also be expressed for use as a control to determine whether the observed interaction is specific for the bait moiety. Due to the instability of PKA, it is advisable to label both the bait protein and the unrelated control fusion protein simultaneously (in separate reactions).

BCU WEST CAMPUS LIBRARY

3. Add 170 µl ice-cold Z′-KCl (to stop reaction) and store on ice until use.

4. Prepare a gel filtration column by pouring Sephadex G-50 equilibrated in Z′-KCl into a 3-ml disposable plastic column (or a 3-ml syringe with a glass wool plug) for a final bed volume of ~3 ml. Allow the column to drain until the level of the buffer is at the top of the column bed.

   The Sephadex G-50 can be swelled in water or buffer and stored at 4°C for months. In this case, five to ten column volumes of Z′-KCl can be used to equilibrate the column after it is poured.

5. Load the entire phosphorylation reaction (from step 3) onto the column and collect the effluent in a 1.5-ml microcentrifuge tube. Place a second tube under the column, add a 200-µl aliquot of Z′-KCl, and collect the effluent again. Repeat the above loading and collecting steps an additional ten times to collect a total of twelve 200-µl fractions.

6. Measure the Cerenkov counts with a scintillation counter to identify the fractions with the highest specific activities, and calculate cpm/µl.

   Typically two peaks of radioactivity are observed. The first peak elutes in fractions five to nine and corresponds to labeled protein. The second peak, usually found in the last few fractions collected, corresponds to unincorporated ATP and should be discarded. The hottest fraction(s), which elute first, should be used. Fractions can be stored at 4°C for several weeks.

7. *Optional:* Analyze a small amount (1 to 2 µl) of the ^{32}P-labeled protein probe by SDS-PAGE and autoradiography (*UNITS 10.1 & 10.11*).

   Typically two strong signals are observed: one at the predicted size of the GST-bait fusion protein and the other at the predicted molecular weight of the GST alone (28 kDa). This is due to the fusion protein's inherent susceptibility to protease cleavage at the GST-bait protein junction. The presence of labeled GST protein in the probe should not interfere with the screen; a control experiment with labeled GST will be performed at the later stages of screening.

Prepare host strain cells and dilution of bacteriophage cDNA library

8. Using serial dilution, determine the titer of the bacteriophage cDNA library.

   See Lech and Brent (1988) for serial dilution procedure.

9. Grow an overnight 50-ml culture of *E. coli* Y1090r$^-$ (or other appropriate host strain; *APPENDIX 4B*) in LB medium containing an appropriate selective antibiotic, 10 mM $MgSO_4$, and 0.2% maltose.

10. Centrifuge cells 10 min at 2000 × *g*, room temperature, and resuspend in 25 ml of 10 mM $MgSO_4$.

    The resuspended cells can be stored up to 1 week at 4°C before use.

Prepare the filters to screen the bacteriophage cDNA expression library

11. Soak eight 137-mm nitrocellulose filters in 10 mM IPTG for 15 min at room temperature and air dry.

    IPTG-impregnated filters can be stored in a petri plate until use.

12. Prepare eight 1.5-ml microcentrifuge tubes each containing 0.6 ml Y1090r$^-$ cells (from step 10) and ~40,000 pfu bacteriophage (from step 8), and incubate 15 min at 37°C.

BCU IASL / CENTRAL UNIVERSITY LIBRARY

13. Add contents of each tube to 7 ml of 0.7% top agarose at 47°C and pour onto 150-mm LB plates (with antibiotic, if necessary). Incubate plates ~3 hr at 42°C, until small plaques are visible.

14. Overlay the plates with IPTG-impregnated filters and incubate an additional 6 to 8 hr at 37°C.

    Formation of plaques in the absence of induction of the lacZ gene promoter ensures that any library-encoded proteins that are deleterious to phage growth will not be expressed while the phage are forming a plaque.

    Incubation in the presence of IPTG-impregnated filters is usually performed for a 6- to 8-hr period, but can proceed overnight for convenience.

15. Chill plates 15 min (or overnight) at 4°C.

16. Pierce each filter in several locations with a 22-G needle dipped in India ink to mark orientation. Remove filters from plates and wash 15 min in TBS-T at room temperature with shaking.

Screen bacteriophage cDNA expression library

17. Incubate filters 1 to 4 hr with rocking at 4°C in 100 ml HBB.

    This blocking step (to reduce nonspecific binding) can also be performed overnight for convenience.

18. Incubate overnight with rocking at 4°C in BB containing 2.5–5 × 10^5 cpm/ml of radiolabeled fusion protein (from step 6).

    All eight filters can be placed in one 150-mm plate and probed with 30 to 40 ml of solution. The plate is wrapped in Parafilm and placed in a Plexiglas box for shielding. Alternatively, the filters can be placed with solution in a heat-sealable bag. The probe solution can be stored at 4°C and used for the subsequent secondary and tertiary screenings.

19. Wash membrane filters three times, 10 min each, in 100 ml BB with shaking at room temperature. Air dry and expose to film (see *UNIT 10.11*).

20. Using the large end of a Pasteur pipet, take an agarose plug at the position of the positive clone. Place into a 1.5-ml microcentrifuge tube and add 1 ml SM and 1 drop of chloroform.

    Agarose plugs can be stored at 4°C for months. Therefore, if many putative positive clones are identified in the primary screen, they can all be stored for future analysis if necessary.

21. Determine the titer by serial dilution and perform successive screening procedures to obtain purified clones.

    See Lech and Brent (1988) for serial dilution procedure and Quertermous (1987) for screening methods.

    Subsequent screens are performed on 100-mm LB plates with ~2000 pfu/plate for secondary screens and ~300 to 500 pfu/plate for tertiary screens. Before purified clones are obtained (usually during the tertiary screen), a control to eliminate clones that might interact with the GST fusion portion of the probe should be performed. To do this, cut the filters in half and probe one half with the labeled GST fusion to the protein of interest and the other with labeled GST alone or an unrelated control GST fusion protein (see Fig. 19.3.1).

BCU MED / CENTRAL UNIVERSITY LIBRARY

REAGENTS AND SOLUTIONS

Use deionized, distilled water in all recipes and protocol steps. All solutions should be prepared from sterile, autoclaved stock solutions, except Z′-KCl, which should be filter sterilized. For common stock solutions, see ***APPENDIX 2A****; for suppliers, see* ***SUPPLIERS APPENDIX****.*

Binding buffer (BB)

20 mM HEPES·OH, pH 7.4
7.5 mM KCl
0.1 mM EDTA
2.5 mM $MgCl_2$
1% (w/v) nonfat dry milk

The solution can be prepared without milk and stored indefinitely at room temperature (add milk prior to use).

HEPES blocking buffer (HBB)

20 mM HEPES·OH, pH 7.4
5 mM $MgCl_2$
1 mM KCl
5% (w/v) nonfat dry milk

The solution can be prepared without milk and stored indefinitely at room temperature (add milk prior to use).

PKA buffer, 10×

200 mM Tris·Cl, pH 7.5 (*APPENDIX 2E*)
10 mM DTT
1 M NaCl
120 mM $MgCl_2$
Store up to 6 months at room temperature

Suspension medium (SM)

5.8 g NaCl
2 g $MgSO_4 \cdot 7H_2O$
50 ml 1 M Tris·Cl, pH 7.5 (*APPENDIX 2E*)
5 ml 2% (w/v) gelatin
H_2O to 1 liter
Sterilize by autoclaving.
Store up to several months at 4°C

Gelatin is prepared by adding 2 g gelatin to 100 ml H_2O, then autoclaving to dissolve when needed.

Tris-buffered saline with Triton X-100 (TBS-T)

10 mM Tris·Cl, pH 8.0 (*APPENDIX 2E*)
150 mM NaCl
0.05% (v/v) Triton X-100
Store up to 6 months at room temperature

Z′-KCl

25 mM HEPES·OH, pH 7.4
12.5 mM $MgCl_2$
20% (w/v) glycerol
100 mM KCl
1 mg/ml BSA
1 mM DTT
Filter sterilize
Store up to 6 months at 4°C

RGUIAS / CENTRAL UNIVERSITY LIBRARY

Background Information

Historically, interacting proteins have been isolated by biochemical approaches, which required purification of the interacting protein for antibody production or microsequencing before a clone encoding the protein could be identified. Two of the molecular biological approaches described in this chapter, the yeast two-hybrid system (*UNIT 19.2*) and phage-based interaction expression cloning (this unit), however, directly yield a clone encoding the interacting protein.

Bacteriophage cDNA expression libraries are commonly screened using antibodies (see St. John, 1990 and references therein) or radiolabeled DNA probes to identify DNA-binding proteins (see Singh, 1991 and references therein). Modifications to identify interacting proteins include screening with the protein of interest (the bait protein) and detecting that protein with antibodies (Chapline et al., 1993). However, by screening with a radiolabeled protein probe, one avoids the additional incubations and washes which are necessary for immunodetection but that increase the likelihood of disrupting weak protein-protein interactions. ^{125}I-labeled protein probes have been used successfully to screen for interacting proteins (Hoeffler et al., 1991), although the technique described in this unit avoids the need to label the proteins with ^{125}I, and the complications of handling this isotope.

Protein probes autophosphorylated with ^{32}P were originally used to screen cDNA expression libraries in the isolation of proteins that interact with receptor protein kinases, a technique referred to as CORT (cloning of receptor targets; Skolnik et al., 1991; Lowenstein et al., 1992; Margolis et al., 1992). By introducing a PKA recognition site into the protein probe, the technique was made suitable for proteins that were not themselves protein kinases (Blanar and Rutter, 1992; Kaelin et al., 1992).

Phage-based interaction expression cloning as described in this unit has been used successfully to identify many interacting proteins, but may not be successful for all types of interactions. For example, many related proteins (known as A-kinase anchoring proteins, or AKAPs) have been identified by their ability to interact with the type II cAMP-dependent kinase regulatory subunit, RII (Carr and Scott, 1992). All the AKAPs can bind RII under denaturing conditions (Lester et al., 1996), illustrating that the success of interaction cloning is often dependent on the nature of the interactions and that interactions less dependent on three-dimensional structure may be favored. However, there are many examples of proteins identified by this technique that cannot interact under the denaturing conditions often used to confirm the binding (commonly referred to as overlay assays or Far Western analysis). For example, a protein domain identified by its interaction with a plant receptor–like protein kinase is capable of interacting with a denatured form of the bait protein, but is unable to interact when the interacting protein is denatured (Stone et al., 1994). This fact is consistent with the idea that immobilization on membranes denatures some proteins but not others.

Critical Parameters and Troubleshooting

The success of phage-based interaction expression cloning is inherently dependent on the quality of the protein probe used and the extent of representation of the bacteriophage cDNA library. GST fusion proteins are often obtained in high quantity in a soluble form, avoiding the necessity of solubilizing and refolding during protein purification from *E. coli* extracts. In most cases the PKA recognition site is readily accessible, and allows production of radiolabeled protein with a high specific activity.

The strength of the protein-protein interaction is also critical. Depending on the nature of the interaction, a filter-binding technique might not be suitable. This technique may not detect weak or transient interactions, such as an enzyme/substrate interaction, and techniques such as the yeast two-hybrid system (*UNIT 19.2*) might be more appropriate.

If no positive clones are identified or if background is high, it may be helpful to add reducing agents or detergents or to alter the salt conditions of the binding and wash solutions (Vinson et al., 1988). Moreover, denaturation and renaturation of the proteins on the filters using 6 M guanidine·HCl (Singh, 1991) may facilitate the recovery of clones expressing interacting proteins, because adsorption of the β-galactosidase fusion proteins to nitrocellulose filters may alter the conformation of the proteins.

For a discussion of common problems with this procedure and their diagnosis and possible solutions, see Table 19.3.1.

Anticipated Results

Depending on the nature of the interaction being sought by this technique, many interact-

BAYLOR COLLEGE OF MEDICINE LIBRARY

Table 19.3.1 General Troubleshooting Guide for Interaction Cloning

Problem	Possible cause	Solution
High background	Insufficient washing	Use more BB wash solution
	Poor choice of nitrocellulose membrane filters	Try a different supplier for membranes
	Insufficient blocking	Block overnight in HBB
No positive plaques	Poor-quality protein probe	Check the probe by SDS-PAGE and autoradiography
	Wash conditions too stringent	Reduce wash times
		Vary salt and/or detergent concentration
	Poorly folded library fusion proteins	Perform 6 M guanidine·HCl denaturation/renaturation (Singh, 1991)
Too many positive plaques	Wash and binding conditions insufficiently stringent	Increase salt and/or detergent in BB
	Library biased to proteins that interact with the affinity tag	Include unlabeled affinity tag in blocking, binding, and wash solutions

ing clones, none, or just a few may be identified. However, the technique is as simple as screening a library by hybridization and often well worth the effort. In any case, observed interactions should be confirmed by other means.

Time Considerations

The interaction cloning technique described in this unit is extremely rapid in comparison with other techniques to identify interacting proteins, such as the yeast two-hybrid system (*UNIT 19.2*). The technique does not require any unusual reagents that would not be readily available in any laboratory routinely engaged in molecular biology, other than the cAMP-dependent protein kinase. Once the appropriate recombinant fusion protein and cDNA expression library are obtained, the primary screen can be completed in a few days. Once the appropriate construct for expression of the GST-bait is obtained, purification of the recombinant GST-bait protein can be achieved in 1 day. ^{32}P labeling of the bait protein requires 2 hr (several additional hours if the optional SDS-PAGE and autoradiography are performed). The initial screening of the bacteriophage cDNA library takes 3 days; day 1 to prepare the filters and induce expression of library-encoded proteins, day 2 for blocking and probing overnight with ^{32}P-labeled bait protein, and day 3 for washing and autoradiography. Subsequent purification of the cDNA clones should only take an additional week. There are a number of steps that can be performed either rapidly or overnight, providing a great deal of convenience and flexibility.

SUPPLEMENT INDEX

How to Use This Index

A new main index is provided once a year. Thereafter, with the next three supplements, a cumulative supplement index, which amends the main index, will be provided. Thus, readers should consult both the main index and the supplement index when seeking an entry, as page numbers may change for replacement units and new entries will added.

A

α-amino group, in sequential chemical ligation, 18.4.7 (fig.)
Absorption spectroscopy, quantitation of nucleic acids using, APPENDIX 4K
Acid blob domain
  expression cassette containing, 19.2.36
  protein fusions to, 19.2.1
Activation domain, acid blob, 19.2.36
Activator protein GLA4, fusion with LexA, 19.2.8
Adsorption, and elution location
  GF chromatography, 8.3.29
  ion-exchange chromatography, 8.2.3-8,2,4, 8.2.10-8,2,13
Affinity chromatography, purifying fusion proteins by, 18.4.8, 18.4.14–18.4.15
Agarose, gel electrophoresis, APPENDIX 4F
Air bubbles, GF column, causes and removal of, 8.3.28–8.3.29
Alcohol dehydrogenase (ADH), promoter pEG202, 19.2.7
Alkali-soluble contaminants, removal from ion-exchange media, 8.2.24
Alu
  nucleotide sequence database search
    BLASTN, 2.5.5, 2.5.17–2.5.19
    TBLASTN and TBLASTX, 2.5.5
  peptide sequence database search, BLASTP and BLASTX, 2.5.4
Amino acid
  α-amino group, in sequential chemical ligation, 18.4.7 (fig.)
  derivatives, used in polypeptide synthesis, 18.4.2 (table), 18.4.10–18.4.11
  unnatural, site-specific incorporation, 18.4.1
Amino acid sequence
  enzymatic approaches for obtaining, UNIT 16.7
  search using BLAST programs, UNIT 2.5
Aminopeptidase, use in ladder sequencing, UNIT 16.7
cAMP-dependent protein kinase, for protein identification, 19.3.8
Amino-terminal cysteine-containing peptides, synthesis of, 18.4.2
Amino-terminal cysteine residue, from chemical synthesis of proteins, 18.4.2
Ammonium sulfate, protein precipitation using
  basic theory, A.3F.1
  common applications, A.3F.1–A.3F.3
  tables, A.3F.3–A.3F.7
Amplification
  enzymatic of DNA, by PCR, A.4J.2–A.4J.5
  of recombinant vaccinia virus, 5.13.12–5.13.13
Anion-exchange chromatography, *see* Ion-exchange chromatography
Antibiotic resistance, plasmid markers for, alteration of, 19.2.36
Antimicrobial agents, for ion-exchange media storage, 8.2.25
Association rate constant k_{assoc}, 19.1.3–19.1.4
ATM gene, coding sequence, 2.5.11–2.5.12
[γ-^{32}P]ATP, for enzymatic phosphorylation, 19.3.1
Available capacity
  defined, 8.2.8
  determination of, 8.2.19

B

Bacterial colonies, growth in media
  isolating single colonies
    by spreading a plate, A.4B.2
    by streaking a plate, A.4B.2
  isolating and titering bacterial colonies by serial dilutions, A.4B.2
  larger cultures, A.4B.1
  monitoring, A.4B.1
  overnight cultures, A.4B.1
  replica plating, A.4B.3
  strain storage and revival, A.4B.3
Bacteriophage
  libraries
    cDNA expression, screening of, 19.3.5
    λ-derived, for protein identification, UNIT 19.3
  protein expression
    for biosynthesis of polypeptides, 18.4.8
    for phage-based expression cloning, 19.3.1–19.3.2
Bait protein
  characterizing, 19.2.3–19.2.11
  used in expression cloning, UNIT 19.3
  immunoblot analysis, for fusion protein, 19.2.10
  interactor hunts with, multiple simultaneous, using interaction mating, 19.2.23
  plasmid pEG202 for expressing, 19.2.1
  testing, 19.2.37
  toxic
    alternate hunt with interaction mating, 19.2.23
    reducing exposure of yeast to, 19.2.35
Basic Local Alignment Search Tool, *see* BLAST
Batch adsorption
  vs column purification, 8.2.3–8.2.4
  ion-exchange media for, 8.2.4 (table)
  and step-gradient elution, ion-exchange chromatography, 8.2.10–8.2.13
Bead diameter, and column purification, 8.2.4–8.2.7 (table)
Bed compression, GF chromatography, 8.3.28
β-galactosidase proteins, in phage-based interaction cloning, 19.1–19.2, 19.3.7
Binding pH, for ion-exchange chromatography, 8.2.1 (fig.), 8.2.16–8.2.18
Biological effects, equilibrium and kinetic considerations in, 19.1.4
Biosynthesis
  of N-terminal cys polypeptides, 18.4.8
  recombinant techniques for αthioester polypeptides, 18.4.19 (fig.)
BLAST (Basic Local Alignment Search Tool)
  accessing, binaries and documentation, 2.5.1–2.5.2
  alignment, 2.5.10 (fig.), 2.5.14 (fig.), 2.5.16 (fig.), 2.5.19 (fig.), 2.5.24–2.5.25
  filtering sequences, 2.5.6
  nucleotide sequence databases, 2.5.4–2.5.5
  parameters, 2.5.28
  peptide sequence databases, 2.5.3–2.5.4
  pull-down menus, 2.5.28
  query sequence
    example in FASTA format, 2.5.5
    formatting, 2.5.5–2.5.6
  results
    reporting, 2.5.21
    viewing, 2.5.6
  search programs compared, 2.5.2, 2.5.3 (table)
  search strategies
    basic vs advanced, 2.5.2
    examples, 2.5.6
    for genomic DNA sequences, 2.5.23
    for low-complexity regions, 2.5.21
    for mRNA sequences, 2.5.21–2.5.23
    for short sequences, 2.5.23
  sequence alignment algorithms, 2.5.24–2.5.25
  sequence identifier syntax, 2.5.29
  See also BLASTN; BLASTP; BLASTX; PSI-BLAST; TBLASTN
BLASTN
  alignment, 2.5.19 (fig.)
  characterized, 2.5.17–2.5.19
  reports, examples of
    graphical view, 2.5.18 (fig.)
    hit list, 2.5.17 (fig.)
  See also BLAST
BLASTP
  alignment, 2.5.10 (fig.)
  characterized, 2.5.6–2.5.11
  and PSI-BLAST, 2.5.19–2.5.21
  report
    graphical view, 2.5.8 (fig.)
    hit lists, 2.5.9 (fig.), 2.5.22 (fig.)
    top portion, 2.5.7 (fig.)
  search, using NCBI's WWW interface, 2.5.7 (fig.)

Boc, *see* t-butyloxycarbonyl
Boc-amino
acyl-3-mercaptopropionamide-MBHA resin, for polypeptide synthesis, 18.4.11
Boc-polypeptide-3-mercaptopropionamide-MBHA resin, for polypeptide synthesis, 18.4.16
Boc-SPPS of α-thioester polypeptides, requirements for, 18.4.15
Breakthrough capacity of ion-exchange columns, measurement of, 8.2.20–8.2.21
3-bromopropionic acid, symmetrical anhydride of, coupling to MBHA resin, 18.4.10–18.4.11
Brookhaven Protein Data Bank (PDB), 2.5.3
Butanol, in DNA precipitation, A.4E.2
t-butyloxycarbonyl (Boc), for peptide synthesis, 18.4.2, 18.4.11

C

C. elegans, genome sequence, 2.5.15–2.5.17
Calcium chloride, introduction of plasmid DNA into cells using, A.4D.1
Calibration, GF chromatography
maintenance of, 8.3.28
standards for, 8.3.22
molecular size determination, 8.3.19–8.3.21, 8.3.24 (table)
Calmodulin-binding protein affinity tag, 19.3.1
Capacity
available, 8.2.8, 8.2.19
breakthrough, 8.2.20–8.2.21
dynamic, 8.2.4–8.2.7 (table), 8.2.8, 8.2.20–8.2.21
for ion-exchange media, comparisons of, 8.2.4–8.2.7 (table)
ionic or total, 8.2.5–8.2.7 (table), 8.2.8
Carboxypeptidases, use in ladder sequencing, UNIT 16.7
Cation exchange chromatography
See Ion-exchange chromatography
CBD (chitin binding domain), in polypeptide synthesis, 18.4.2–18.4.3, 18.4.19–18.4.20
cDNA library
expression, UNIT 19.3
expression cassette, pJG4-5, 19.2.35–19.2.36
screening, 19.2.34
CDS, for peptide sequence databases, 2.5.3
Chemical cleavage of polypeptides, in natural chemical ligation, 18.4.2 (table)
Chemical synthesis of polypeptides
α-thioester, 18.4.8–18.4.12
N-terminal cys-polypeptides, 18.4.8
Nα(Msc)-cys, α-thioester, 18.4.15–18.4.16
Chicken embryo fibroblasts (CEF), preparation of modified vaccinia virus (MVA) stock, 5.12.6–5.12.10
Chitin bead slurry, used in bacterial expression of polypeptides, 18.4.14
Chitin binding domain (CBD), in polypeptide synthesis, 18.4.2–18.4.3, 18.4.19–18.4.20
Chromatographic separations, ion-exchange, UNIT 8.2
Chromatographic titration curves, 8.2.25–8.2.27
Chromatography, ion-exchange, UNIT 8.2

PRINCETON / CENTRAL - UNIVERSITY - LIBRARY

Dropout medium for yeast growth
for interactor hunts, 19.2.34
plates, complete minimal (CM) medium, selecting a library plasmid with, 19.2.11
powder, CM medium (recipe), A.4L.2
plates, CM medium (recipe), A.4L.3
DUST filtering program, for BLASTN, 2.5.28
Dynamic capacity, for column purification
defined, 8.2.8
measurement of, 8.2.20–8.2.21
media compared, 8.2.5–8.2.7 (table)

E

E. coli
for bacterial expression of α-thioester polypeptides, 18.4.12–18.4.15
extracts, protein purification from, 19.3.1, 19.3.7
Eddy dispersion, in GF chromatography, 8.3.26
Electroporation
Escherichia coli KC8, interactor protein hunt, 19.2.23
for plasmid transfer, from yeast to *Escherichia coli*, 19.2.19–19.2.20
Electrospray ionization mass spectrometry (ESI-MS)
for in-line detection of molecular mass, 8.3.25
versus MALDI-MS, 16.4.1
Elution
for GF chromatography, elution volume
desalting procedure, 8.3.6
determining, 8.3.12–8.3.13
for ion-exchange chromatography
batch adsorption and step-gradient, 8.2.10–8.2.13
column chromatography with linear gradient, 8.2.13–8.2.16
pH-based step gradient, 8.2.13
EMBL (European Molecular Biology Laboratory), 2.5.3, 2.5.29 (table)
Endoprotease Lys-C, for in-gel digestion of proteins, 16.4.4
Enthalpy, and equilibrium, protein-protein interactions, 19.1.3
Entrez database links, 2.5.11
Enzymatic sequencing, UNIT 16.7
Enzymes
aminopeptidase M, for ladder sequencing, UNIT 16.7
carboxypeptidase A, P, and Y, for ladder sequencing, UNIT 16.7
endoprotease-Lys-C, 16.4.4
Enzyme-substrate interactions, rate of dissociation, 19.1.4
Equilibrium association constant K_a, protein-protein interactions, 19.1.2
Equilibrium parameters in protein interactions, 19.1.1–19.1.3
Escherichia coli
electroporation transfer to, 19.2.19–19.2.20, 19.2.23
interaction trap components, 19.2.4–19.2.5 (table)
EST, *see* Expressed sequence tag
Ethanol, in DNA precipitation, A.4E.1
European Molecular Biology Laboratory (EMBL), 2.5.3, 2.5.29 (table)
Exclusion limit, in selecting matrices for desalting, 8.3.1
Expressed sequence tag (EST), databases
BLAST, 2.5.4
BLASTN, 2.5.18
in screening for protein identification, 16.5.4
TBLASTN, 2.5.12–2.5.13
Expression cloning UNIT 19.3
Expression libraries, use in protein identification, UNIT 19.3
Expression systems
vaccinia, UNITS 5.11–5.15
VOTE, 5.15.6–5.15.8
Expression vectors
for biosynthesis of polypeptides, 18.4.8
in *E. coli* expression systems, for GST fusion proteins, 19.3.1, 19.3.7
for phage-based interaction cloning, 19.3.1–19.3.2
E values (Expect values), for BLAST sequence studies
database designation, 2.5.9
parameters, 2.5.28
in PSI BLAST search, 2.5.19–2.5.21
statistical significance, 2.5.21

F

FASTA (software), for sequence search, 2.5.5–2.5.6, 2.5.24
Fingerprint mapping
MALDI-MS, UNIT 16.4
MS-Fit program used in, UNIT 16.5
Filtering for sequence similarity searching
DUST program, 2.5.28
low-complexity regions, BLAST search, 2.5.21
SEG program, 2.5.28
Flow-dependent zone broadening, in GF chromatography, 8.31
Flow rate
GF chromatography
controlling, 8.3.28
and matrix selection, 8.3.2–8.3.3
maximizing in desalting, 8.3.26
for optimizing protein fractionation, 8.3.26–8.3.27
for protein fractionation, GF chromatography, 8.3.16 (table)
in ion-exchange chromatography, 8.2.10
9-fluorenyloxycarbonyl (Fmoc) SSPS, for peptide synthesis, 18.4.2 (table)
Fmoc, *see* 9-fluorenyloxycarbonyl
Fusion protein
affinity purification, 18.4.8, 18.4.15
expression from *E. coli* BL21, 18.4.14
generation of, 18.4.2–18.4.3
immunoblot analysis to confirm construction, 19.2.28
lacZ, yeast strain containing, A.4L.4
LexA binding domain, with GAL4 activation domain, 19.2.33–19.2.34
Fusion protein junction, in phage-based expression cloning, 19.3.1

G

Galactose/raffinose (GAL/Raff), yeast growth using, for interacting protein selection, 19.2.11
β-Galactosidase, assay
for *lacZ* gene activation, 19.2.8–19.2.9
in liquid yeast culture, A.4L.4
Gel-filtration (GF) chromatography
equilibrium parameters in protein interactions, 19.1.1–19.1.3
equipment, GF chromatography, 8.3.7 (fig.)
history of, 8.3.23–8.3.25
protein desalting chromatogram, 8.3.13 (fig.)
protein fractionation chromatogram, 8.3.16 (fig.)
separating volume chromatogram, 8.3.11 (fig.)
sample processing, desalting protein solutions, 8.3.11–8.3.13
Gel preparation
GF chromatography, protein desalting, 8.3.8
ion-exchange chromatography, 8.2.11-8.2.13
GenBank
vs BLAST searches, 2.5.1
identifier syntax for, 2.5.29 (table)
Genes
intein, for cloning, expression, and purification of polypeptides, 18.4.13 (fig.)
selection for function, yeast growth and maintenance, A.4L.2
General database identifier, syntax for, 2.5.29 (table)
GenInfo Backbone Id database, identifier syntax for, 2.5.29 (table)
Genome sequence, BLAST programs, UNIT 2.5
Genome survey sequence (GSS) database, for BLASTN, TBLASTN, and TBLASTX, 2.5.5
Gibbs free energy, and dissociation constants, protein-protein interactions, 19.1.2–19.1.3
gi identifier, for sequence database searching, 2.5.5, 2.5.29
Glassware, silanizing, APPENDIX 3E
Glucose yeast growth using, to select a library plasmid, 19.2.11
Glycerol solution (recipe), 19.2.33
Gradient-formation techniques
apparatus for, 8.2.22 (fig.)
peristaltic pumps, 8.2.22–8.2.23
positive-displacement pumps, twin, 8.2.23
simple gradient mixers, 8.2.21
switch-valve-based gradient mixing, 8.2.22
Gravity flow, GF chromatography, open-bed column, 8.3.6
Group separation, *see* Desalting
GSS (Genome survey sequence), 2.5.5
GST affinity tag, 19.3.1, 19.3.8
GST-bait protein, ^{32}P-labeled, 19.3.1, 19.3.8
λgt11 expression vector, 19.3.1–19.3.2 (fig.)

H

HCCA (α-cyano-4-hydroxy-*trans*-cinnamic acid)
matrix for MALDI mass analysis, 16.3.1
matrix for PSD analysis, 16.6.6
purification/recrystallization of, 16.3.3–16.3.4
Heat shock protein 70, isolation of, in interactor hunts, 19.2.34
High-performance size-exclusion chromatography (HPSEC), 8.3.25
High-throughput genomic (HTG) sequence databases, for BLASTN, TBLASTN, and TBLASTX, 2.5.4
Histidine affinity tag, 19.3.1
Homology searching, for protein identification, 16.6.6
HTG or HTGS (High-throughput genomic sequence) database, 2.5.4
Human EST sequences, search using BLASTN, 2.5.17–2.5.19
Human genome, BLAST program databases, UNIT 2.5
Hybridization, yeast colony, 19.2.30–19.2.31
Hybridization analysis, of DNA blots
blocking agents, alternative, A.4H.2 (table)

cloning vectors incorporating promoters for bacteriophage RNA polymerases, A.4H.6 (table)
high-salt solutions used in, A.4H.1 (table)
hybrid stability and hybridization rate, A.4H.2 (table)
probes
radiolabeled DNA, A.4H.1–A.4H.4
radiolabeled RNA, A.4H.5–A.4H.7
removal from hybridized membranes, A.4H.7
spin-column procedure for separating radioactively labeled DNA from unincorporated dNTP precursors, A.4H.8
troubleshooting guide, A.4H.3–A.4H.5 (table)
Hydrodynamic volume V_h
GF column, 8.3.21
and molecular size, 8.3.25
Hydrophobic contaminants, removal from ion-exchange media, 8.2.24

I

^{125}I, for protein labeling, 19.3.7
Identifier syntax for sequence databases, 2.5.29 (table)
Immunoblotting
in interactor hunts, 19.2.37
protein extract preparation for, 19.2.28
recombinant vaccinia virus, expressed protein detection, 5.14.7–5.14.8
Immunoprecipitation
recombinant vaccinia virus, expressed protein detection, 5.12.8–5.12.9, 5.14.11
measuring, kinetic considerations and equilibrium constants, 19.1.4
Immunostaining
recombinant vaccinia virus, 5.13.14–5.13.15
titration of MVA stocks, 5.12.9–5.12.10
Infection, vaccinia, 5.11.2–5.11.3
In-gel digestion of proteins, for peptide mass mapping, 16.4.2–16.4.4
Institute for Genomic Research, The (TIGR), 2.5.2
Intein, as protein splicing element, 18.4.2–18.4.3, 18.4.19
Intein-CBD (chitin binding domain) construct, in polypeptide synthesis, 18.4.2–18.4.3, 18.4.13 (fig.)
Interacting proteins, identification by phage-based expression cloning, UNIT 19.3
Interaction affinity, multiple measurements of, 19.2.34–19.2.35
Interaction cloning, UNIT 19.3
Interaction mating, interactor hunt using, 19.2.23–19.2.26, 19.2.37
Interaction trap
components of, 19.2.4–19.2.5 (table)
libraries compatible with, 19.2.14–19.2.16 (table)
yeast selection strains, 19.2.8 (table)
Interaction trap/two-hybrid system, to identify interacting proteins, UNIT 19.2
Interactor hunt
performing, 19.2.11–19.2.21
plasmid construction step, 19.2.3–19.2.5
Introns, in BLASTX sequence search, 2.5.13
Ion-exchange chromatography
aqueous solutions, preparation of, 8.2.8
background and parameters, 8.2.25, 8.2.27, 8.2.30
batch adsorption and step-gradient elution, 8.2.10–8.2.13
batch technique vs column purification, 8.2.3–8.2.4
buffer systems, 8.2.2–8.2.3 (table)
column capacity, 8.2.4–8.2.8, 8.2.20–8.2.21 (fig.)
column chromatography
with linear gradient elution, 8.2.13–8.2.16
results, example, 8.2.29 (fig.)
scale-up calculations for, 8.2.9 (table), 8.2.10
contaminants, removal of, 8.2.24
gradient formation techniques, 8.2.21–8.2.23
gradient mixer (apparatus), 8.2.22 (fig.)
ion-exchange media, 8.2.2, 8.2.4–8.2.7 (table), 8.2.8, 8.2.23–8.2.25
optimization, 8.2.25–8.2.27
peristaltic pump illustrated, 8.2.23 (fig.)
pH-based step gradient elution, 8.2.13
pH ranges and net charge of protein, 8.2.1 (fig.)
protein purity and time considerations, 8.2.30
salt concentration, 8.2.10–8.2.13, 8.2.18–8.2.19
starting conditions, determination of, 8.2.16–8.2.19
systems compared, 8.2.8–8.2.9
titration curves, 8.2.25–8.2.27
troubleshooting guide, 8.2.28–8.2.29
Ion-exchange gel
adsorption of sample to, 8.2.11–8.2.12
elution with step gradient of increasing salt concentration, 8.2.12
regeneration for reuse, 8.2.12–8.2.13
swelling and equilibrating, 8.2.11
Ion-exchange media
for batch adsorption, 8.2.4 (table)
cleaning and regeneration, 8.2.23–8.2.24
protein capacity, 8.2.4–8.2.8
selection, 8.2.2
storage, 8.2.24–8.2.25
See also Capacity
Ion exchanger, for scale-up conditions, 8.2.9
Ionic capacity
for column purification, 8.2.5–8.2.7 (table)
defined, 8.2.8
See also Capacity
Ionic-exclusion effects, from solute-matrix interactions, 8.3.29
IPTG-impregnated filters, for bacteriophage cDNA library, 19.3.4
Isoelectric point (pI), for ion-exchange chromatography, 8.2.1–8.2.2
Isopropanol, in DNA precipitation, A.4E.2
Isotopes, for protein labeling, 19.3.7

K

Kinetic parameters, protein interactions, 19.1.1, 19.1.3–19.1.4

L

Ladder sequencing, on-target, UNIT 16.7
Laemmli buffers, 19.2.33
Lambda-derived expression libraries, 19.3.1
Leucine (Leu), requirement for, protein interaction systems, 19.2.1, 19.2.37–19.2.38
LexA, bait protein fusion with, 19.2.1
Library strain, pretransformed, preparing, 19.2.24
Ligation, native chemical
mechanism of, 18.4.3 (fig.)
of three polypeptides, sequential, 18.4.6–18.4.7
of two polypeptides, 18.4.3–18.4.6
See also Bacteriophage
Ligation buffer, preparation of, 18.4.4
Ligation reaction, for protein synthesis, UNIT 18.4
Ligation site
and peptide bond formation, 18.4.3 (fig.)
selection of, 18.4.1–18.4.2
Linear-gradient elution, and column chromatography, 8.2.12–8.2.16
Liquid chromatography/ESI-MS, peptide mass determination using, 16.5.1
Liquid column chromatography system with gradient maker, 8.2.14 (fig.)
Lithium acetate transformation
modification for interactor hunts, 19.2.38
of yeast, A.4L.5–A.4L.6, 19.2.7–19.2.8
Lysis, for specificity screening in protein interactions, 19.2.33

M

MALDI-CID (collision-induced dissociation), sequence analysis using, 16.6.1, 16.6.4–16.6.5
MALDI-MS (matrix-assisted laser desorption/ionization mass spectrometry)
for amino acid sequencing, UNIT 16.7
fingerprint mapping, in-gel digestion of proteins for, UNIT 16.4
peptide and protein analysis, sample preparation, UNIT 16.3
standards
molecular size, for gel filtration columns, 8.3.24 (table)
nonprotein polymer, for molecular size determination, 8.3.21
MALDI-TOF, peptide mass analysis, 16.5.4, 16.6.5
Mammalian cells, protein expression using vaccinia system, UNITS 5.11 and 5.19
Mass, accuracy of measurement, and protein identification, 16.5.3, 16.6.6
Mass spectrometry (MS)
with gel filtration
delayed-extraction MALDI-reflection-TOF, protein digest, 16.5.4 (fig.)
for molecular mass determination, 8.3.25
MALDI method for enzyme sequencing, UNIT 16.7
See also MALDI entries
Matrices for BLAST programs
BLOSUM-62, 2.5.9–2.5.10, 2.5.23–2.5.24, 2.5.28
effect on PSD analysis, 16.6.6
gel filtration, for desalting, 8.32 (table)
PAM, 2.5.23
for short sequences, 2.5.23 (table)
Matrix-assisted laser desorption/ionization mass spectrometry, for amino acid sequencing, UNIT 16.7
See also MALDI-MS
MBHA resin, for α-thioester polypeptide synthesis
coupling to 3-bromopropionic acid, 18.4.9
and other resins, 18.4.2 (table)
preparation of, 18.4.9
Media
bacterial growth in, APPENDIX 4B
ion-exchange, 8.2.2-8.2.8, 8.2.24-8.2.25
preparation and bacteriological tools, APPENDIX 4A
expression vectors, 5.11.3–5.11.5, 5.13.1–5.13.5

SOUTH WEST CENTRAL UNIVERSITY LIBRARY

gene expression using T7 RNA polymerase hybrid system, UNIT 5.15
recombinant
characterization of, UNIT 5.14
concanavalin A-coated plates, 5.13.15
isolation of DNA, 5.13.8–5.13.9
MVA, live immunostaining, 5.13.14–5.13.15
plaques, 5.13.9–5.13.14, 5.13.17
purification process, 5.13.5–5.13.8
transfection of infected cells, 5.13.1–5.13.5, 5.13.17–5.13.18
stocks, *see* Vaccinia virus stocks
transfer vectors, 5.13.4 (table)
for yeast growth
liquid, A.4L.1–A.4L.2
solid, A.4L.3
3-Mercaptopropionamide-MBHA resin, for polypeptide synthesis
coupling to Boc amino acid, 18.4.11
and other resins, 18.4.2 (table)
preparation of, 18.4.11
Metallic contaminants, removal from ion-exchange media, 8.2.24
Microbial genomes, unfinished, sequencing databases for, 2.5.1–2.5.2
Mito database for BLASTN, TBLASTN, and TBLASTX, 2.5.5
Modified vaccinia virus (MVA), stock
preparation of, 5.12.8–5.12.9, 5.12.11
titration by immunostaining, 5.12.9–5.12.10
Molecular biology techniques
absorption spectroscopy, quantitation of nucleic acids using, APPENDIX 4K
agarose gel electrophoresis, resolution of large DNA fragments on agarose gels
minigels and midigels, A.4F.2
overview, A.4F.1–A.4F.2
bacterial growth in liquid or solid media, APPENDIX 4B
DNA
digestion with restriction endonucleases, APPENDIX 4I
enzymatic amplification by PCR, APPENDIX 4J
purification and concentration from aqueous solutions, A.4E.2
media preparation and bacteriological tools, APPENDIX 4B
PCR, APPENDIX 4J
southern blotting, APPENDIX 4G
storage of, A.4C.3
Molecular size, determination of
by GF chromatography, 8.3.4–8.3.6, 8.3.22
proteins, 8.3.17–8.3.18
Month database
nucleotide sequence for BLASTN, TBLASTN, and TBLASTX, 2.5.4
peptide sequence for BLASTP and BLASTX, 2.5.4
Msc protecting group, used in polypeptide synthesis, 18.4.6–18.4.7, 18.4.15–18.4.16
MS-Fit, UNIT 16.5
MS-Tag, UNIT 16.6
Multiple-angle laser light scattering (MALLS), 8.3.25

N

National Center for Biotechnology Information (NCBI), BLAST programs, UNIT 2.5
Native chemical ligation
background and parameters, 18.4.18–18.4.20
protein synthesis, strategies for, 18.4.1–18.4.3
sequential, principle of, 18.4.7 (fig.)
of three polypeptides, sequential, 18.4.6–18.4.7
of two polypeptides, 18.4.3–18.4.6
NBRF PIR, identifier syntax for, 2.5.29 (table)
NCBI (National Center for Biotechnology Information), BLAST programs, UNIT 2.5
Net charge of protein as function of pH, 8.2.1 (fig.)
nr (nonredundant) database
nucleotide sequence for BLASTN, TBLASTN, and TBLASTX, 2.5.4
peptide sequence for BLASTP and BLASTX, 2.5.3
N-terminal cys polypeptides, synthesis of
biosynthesis methods for, 18.4.8
chemical methods for, 18.4.8
resins and amino acid derivatives for, 18.4.2 (table)
N-terminal residue and sequencing, UNIT 16.7
Nα(methylsulfony)ethyloxycarbonyl-Cys, α-thioester peptide, in chemical ligation, 18.4.6–18.4.7, 18.4.15–18.4.16
Nucleic acids, immobilization materials, A.4G.2 (table)
Nucleotide sequence databases
using BLAST programs, 2.5.4–2.5.5
using TBLASTN, 2.5.12–2.5.15
Nutrients, amino acid, in dropout powders, A.4L.2 (table)

O

Operating pH, for ion-exchange chromatography, UNIT 8.2
Operators, *LexA*, 19.2.1
Orthopoxvirus, 5.11.1, 5.11.5

P

Partner proteins, 19.1.1
PAM matrices, for BLAST, 2.5.23
PAM resin for polypeptide synthesis, 18.4.2 (table)
Patents database, identifier syntax for, 2.5.29 (table)
PCR
defined, A.4J.1
enzymatic amplification of DNA, standard procedures and optimization, A.4J.2–A.4J.5
recombinant vaccinia virus, DNA detection, 5.14.1–5.14.4
PDB, *see* Brookhaven Protein Data Bank
Peptide bond, in native chemical ligation, 18.4.3 (fig.)
Peptide ladders, UNIT 16.7
Peptides
bioactive, small, impact of SPPS on study, 18.4.17
MALDI mass analysis, UNIT 16.3
MALDI-MS, UNIT 16.7
sequence search with BLAST programs, 2.5.3–2.5.4
See also Polypeptides
Peristaltic pumps, for gradient mixing, 8.2.22–8.2.23
pH
in ion-exchange chromatography
and charge of protein, 8.2.1
and ion-exchange media, capacity of, 8.2.4
and ion-exchange media, selection of, 8.2.2
and microbial growth on media and columns, 8.2.24–8.2.25
range for buffers, comparison of, 8.2.3 (fig.)
range for protein binding to anion or cation exchangers, 8.2.1 (fig.), 8.2.16–8.2.18
in native chemical ligation of polypeptides, 18.4.1, 18.4.3, 18.4.6, 18.4.18–18.4.19
pH-based step-gradient elution, 8.2.13
Phage-based expression cloning
use of β-galactosidase protein, 19.3.1–19.3.2, 19.3.7
background and parameters, 19.3.7–19.3.8
bacteriophage cDNA library, 19.3.1, 19.3.4
cDNA expression libraries, 19.3.1
filters for bacteriophage cDNA library, preparation, 19.3.4
host strain cells, preparation, 19.3.4
^{32}P-labeled protein probe, preparation, 19.3.3–19.3.4
schematic representation, 19.3.2 (fig.)
troubleshooting guide, 19.3.8 (table)
Phage, recombinant, in vivo conversion into plasmid DNA, 19.3.2
Phage repressor, equilibrium constant example, 19.1.3
Phenol extraction, in DNA purification, A.4E.1
pI (isoelectric point), in ion-exchange chromatography
and net charge of protein, 8.2.1
for selection of ion-exchange media, 8.2.2
PIR (Protein Identification Resource) database, 2.5.3
^{32}P-labeled GST-bait protein, 19.3.1, 19.3.8
Plaque assays
protein identification, 19.3.7 (table)
recombinant vaccinia virus, 5.13.9–5.13.14
vaccinia virus stocks, 5.12.5–5.12.6
Plasmid DNA
conversion from recombinant phages, 19.3.2
introduction into cells
one-step preparation and transformation of competent cells, A.4D.2
transformation using calcium chloride, A.4D.1
preparation of
boiling miniprep, A.4C.2
in 96-well microtiter plates, A.4C.1–A.4C.2
overview, A.4C.1
storage of, A.4C.3
Plasmids
interaction trap components, 19.2.4–19.2.5 (table)
isolation by transfer into *E. coli*, 19.2.19–19.2.20
lacZ reporter
for interaction mating interactor hunt, 19.2.23–19.2.24
pJK103, 19.2.7 (fig.), 19.2.12

Protein synthesis, using native chemical ligation
background and parameters, 18.4.18–18.4.20
fragment preparation, 18.4.1
ligation site(s), choosing, 18.4.1
See also Native chemical ligation
PSI-BLAST (position-specific iterated BLAST)
characterized, 2.5.19–2.5.21
report example, hit list, 2.5.20 (fig.)
See also BLAST; BLASTP
Pulse labeling, vaccinia virus, 5.15.8–5.15.9
Pumps, in ion-exchange chromatography, 8.2.21–8.2.23
Purification
DNA, A.4E.1–A.4E.2, A.4F.1–A.4F.2
recombinant vaccinia virus, 5.13.5–5.13.8

R

Radiolabeling, of protein, for phage-based interaction cloning, UNIT 19.3
Random coils converting protein shape to, for molecular size determination, 8.3.19
Rapid evaporation method, sample preparation for MALDI-MS, 16.3.1, 16.3.2–16.3.
Reagents and Solutions
Ac_2O/DIEA/DMF solution, 18.4.16
AcSH/DIEA/DMF solution, 18.4.16
binding buffer (BB), 19.3.6
BME/DIEA/DMF solution, 18.4.17
calibration standards, 8.3.22
cell lysis buffer, 5.14.9
cleavage buffer, 18.4.17
column buffer, 18.4.17
complete DMEM-10 or -20, 5.12.10
complete MEM-2.5, -10, or -20, 5.12.11
complete MEM-10/BrdU or -20/BrdU, 5.12.11
complete spinner medium-5, 5.12.11
complete 2× plaque medium-5, 5.13.16
Denhardt solution, A.4H.9
DNA extraction buffer, 5.14.9
gel filtration buffers, 8.3.22–8.3.23
glycerol solution, 19.2.33
Guanidine·HCL buffer, 6 M, 18.4.17
HEPES blocking buffer (HBB), 19.3.6
HF/p-cresol solution, 18.4.17
for interactor hunts, 19.2.33
Laemmli buffers, 19.2.33
low-salt buffer, 5.14.10
lysis buffer, 18.4.17
lysis solution, 19.2.33
for MALDI-MS of peptides and proteins, 16.3.5
media for yeast growth and manipulation, A.4L.1–A.4L.3
PBS/Tween, 5.14.10
peptide matrix/nitrocellulose solution, 16.3.5
PKA buffer, 10×, 19.3.6
salmon sperm DNA, 19..2.28–19.2.29, A.4H.7
for storage and retrieval of yeast stocks, A.4L.3–A.4L.4
suspension medium (SM), 19.3.6
transfection buffer, 5.13.16
Tris-buffered saline with Triton X-100 (TBS-T), 19.3.6
total liquid volume marker, GF chromatography, 8.3.23
void marker, GF chromatography, 8.3.23
Z buffer, yeast growth and manipulation, A.4L.6
Z′-KCl, 19.3.6
Recombinant biosynthesis techniques, for α-thioester polypeptides, 18.4.19 (fig.)
Recombinant phages, in vivo conversion into plasmid DNA, 19.3.2
Recombinant proteins, vaccinia virus detection methods
dot-blot hybridization, 5.14.6–5.14.7

PROTEIN SCIENCE LIBRARY

immunoblotting, 5.14.7–5.14.8
immunoprecipitation, 5.12.8–5.12.9, 5.14.11
Replica plating, isolating single colonies, A.4B.3
Replication, vaccinia virus, 5.11.1–5.11.2
Reporter genes
lacZ, 19.2.3, 19.2.35
LEU2
for bait protein analysis, 19.2.3
for interactor hunts, 19.2.23
Repression assay, fusion-protein synthesis confirmation by, 19.2.10
Resins, used in polypeptide synthesis, 18.4.2 (table), 18.4.10–18.4.11
Resolution, chromatography
GF, 8.3.2
equation for, 8.3.26–8.3.27
Restriction endonuclease digestion
buffers, A.4I.3
cross index of recognition sequences and, A.4I.2 (table)
for library cDNA definition, 19.2.21–19.2.23
single DNA sample with single restriction endonuclease, A.4I.1, A.4I.3
Reversed-phase high-performance liquid chromatography (RP-HPLC), use in polypeptide ligation, 18.3.5, 18.4.3
Rink amide resin for polypeptide synthesis, 18.4.2 (table)
mRNA sequences, analysis using BLAST, 2.5.21–2.5.23
RP-HPLC, *see* reversed-phase high-performance liquid chromatography

S

Saccharomyces cerevisiae, transformation efficiency in, 19.2.38
Salmon sperm DNA
preparation of, A.4H.7
sheared, preparation of, 19.2.28–19.2.29
Salt concentrations, in ion-exchange chromatography
for batch adsorption and step-gradient elution, 8.2.10–8.2.13
determination of, 8.2.18–8.2.19
optimization, 8.2.25–8.2.27
Salt precipitation, protein membrane fractionation, A.3F.2
Sample size, and matrix selection, GF chromatography, 8.3.2–8.3.3
Sample volume, GF chromatography
maximizing, 8.3.25–8.3.26
for protein fractionation, 8.3.16
and resolution, 8.3.11
SEG filtering program, for BLAST, 2.5.28
Selectivity, GF chromatography
for protein fractionation, 8.3.27
versus resolution, 8.3.6
Separating volume V_i
calculating, 8.3.11
for desalting, 8.3.26
Sequence analysis
database search strategies
with BLAST family of programs, 2.5.2, 2.5.6, 2.5.21–2.5.23
with MALDI-CID, 16.6.4–16.6.5
with MS-Fit, UNIT 16.5.
with MS-Tag, UNIT 16.6.
by organism, 2.5.28
searching short sequences, 2.5.23
See also BLAST
Sequence database, see Sequence analysis, database search strategies
Sequence similarity search using BLAST programs, UNIT 2.5
Sequence-tagged site (STS) database, 2.5.4, 2.5.12–2.5.13
Sequential chemical ligation
principle shown, 18.4.7 (fig.)
of three polypeptides, 18.4.6–18.4.7
See also Native chemical ligation
Sheared salmon sperm DNA (sssDNA), preparation of, 19.2.28–19.2.29
Side-chain protecting groups, for polypeptide synthesis, 18.4.2 (table)
Sinapinic acid, matrix for MALDI-MS, 16.3.1
Solid-phase peptide synthesis (SPPS)
of α-thioester polypeptide, 18.4.12
background, 18.4.17–18.4.18
Boc-SPPS of α-thioester polypeptides, requirements for, 18.4.15
Solute interactions with matrices
GF chromatography, 8.3.4, 8.3.27–8.3.28
tailing peaks from, 8.3.29
Southern blot hybridization, recombinant vaccinia virus, DNA detection, 5.14.4–5.14.5, 5.14.10
Southern blotting
dot and slot blotting of DNA
onto a positively charged nylon membrane using a manifold, A.4G.7–A.4G.8
onto uncharged nylon and nitrocellulose membranes using a manifold, A.4G.6–A.4G.7
by downward capillary transfer, A.4G.4
electroblotting from polyacrylamide gel to nylon membrane, A.4G.5–A.4G.6
manual preparation of DNA dot blot, A.4G.8
onto nylon membrane with an alkaline buffer, A.4G.4
onto nylon or nitrocellulose membrane with high-salt buffer, A.4G.1–A.4G.2
UV transilluminator, calibration of, A.4G.3
Specificity tests for bait proteins
procedures, 19.2.20, 19.2.33
frequency and relevance of positive results, 19.2.34
Spectrometry, MALDI-MS for enzyme sequencing, UNIT 16.7
Spin columns, desalting proteins, 8.3.7
SPPS, *see* Solid-phase peptide synthesis
SST (Sequence-tagged site) database, 2.5.4, 2.5.12–2.5.13
Stability, of interacting proteins, 19.1.1
Standards
for MALDI-MS, 16.3.5
molecular size, for gel filtration columns
denatured, use of, 8.3.21
native protein, use of, 8.3.20–8.3.21
nonprotein polymer, use of, 8.3.21
preparation, 8.3.22
selection, 8.3.24 (table)
Step-gradient elution
and batch adsorption with increasing salt concentration, 8.2.10–8.2.12
pH-based, 8.2.13
Stokes radius, as measure of molecular size, 8.3.25
Stringency versus sensitivity of reporters, interactor hunts, 19.2.38
Swiss-Prot database, 2.5.3, 2.5.29 (table)
Switch-valve-based gradient mixing, 8.2.22
Synthesis of proteins, using native chemical ligation of polypeptides, UNIT 18.4

T

T7 RNA polymerase hybrid system, vaccinia virus
confection with two recombinant vaccinia viruses, 5.15.4–5.15.5, 5.15.10
DNA transfection, 5.15.9
expressed protein, detection by pulse labeling, 5.15.8–5.15.9
gene expression using VOTE system, 5.15.6–5.15.8
liposome-mediated transfection following recombinant vaccinia virus infection, 5.15.1–5.15.4
OST7-1 cells, infection of, 5.15.5–5.15.6
Target gene, for polypeptide synthesis, 18.4.13 (fig.)
Target protein
lyophilized, folding of, 18.4.6
pI and pH stability in ion-exchange, 8.2.2
purification for HPLC analysis, 18.4.5
TBLASTN
alignment, 2.5.16 (fig.)
characterized, 2.5.12, 2.5.15–2.5.17
reports, examples of
graphical view, 2.5.15 (fig.)
hit list, 2.5.15 (fig.)
See also BLAST
Tentative human consensus (THC) sequences, databases for, 2.5.2
THC sequences, *see* Tentative human consensus sequences, databases for
The Institute for Genomic Research (TIGR), 2.5.2
Theoretical plates, GF column, calculating, 8.3.15
Thioester linkage, 18.4.19
See also Native chemical ligation
α-Thioester moiety, in polypeptides, 18.4.7 (fig.), 18.4.18
α-Thioester polypeptides
analysis, 18.4.15
bacterial expression, 18.4.12–18.4.15
chemical synthesis, 18.4.9–18.4.12
cleavage and purification, 18.4.12, 18.4.15
solid-phase synthesis
apparatus for, 18.4.10 (fig.)
described, 18.4.12
synthesis, resins and amino acid derivatives for, 18.4.2 (table)
Thiol group of polypeptides, 18.4.3 (fig.), 18.4.6–18.4.12, 18.4.15–18.4.16
See also Polypeptides
TIGR (The Institute for Genomic Research), 2.5.2
Titration methods, vaccinia virus stocks, plaque assay, 5.12.5–5.12.6
Total (ionic) capacity, of ion exchange media, 8.2.5–8.2.7 (table), 8.2.8
Total liquid volume V_t, GF column
marker for, 8.3.10–8.3.11
marker for (recipe), 8.3.23
measuring, 8.3.12
Transcription of reporters, diploid versus haploid yeast, 19.2.23
Transfection, recombinant vaccinia virus, 5.13.1–5.13.5, 5.15.1–5.15.4
Transformation
library, in an interactor hunt, 19.2.16–19.2.16
lithium acetate
interaction trap preparation, 19.2.7–19.2.8
modification for interactor hunts, 19.2.38
of yeast, A.4L.5–A.4L.6, 19.2.7–19.2.8
Transient protein interactions, 19.1.1
Transthioesterification reaction, in chemical ligation, 18.4.3 (fig.)
Tribrid approach, for identifying proteins bound to drug ligands, 19.2.37

BRANDEIS UNIVERSITY / CENTRAL LIBRARY

Trypsin, for digesting gel, fingerprint mapping, 16.4.3–16.4.4
pTYB1 vector, for bacterial expression of polypeptides, 18.4.14
Tyrosine kinase, in tribrid proteins, 19.2.37

V

Vaccinia infection, effects of, 5.11.2–5.11.3
Vaccinia virus
  safety precautions, 5.11.5
  expression system
    replication cycle, 5.11.1–5.11.2
    vector, 5.11.3–5.11.5
  MVA stock
    preparation of, 5.12.8–5.12.9
    titration by immunostaining, 5.12.9–5.12.10
  stocks, cell culture preparation
    general, 5.12.4–5.12.5
    monolayer cells, 5.12.2–5.12.3
    suspended cells, 5.12.3–5.12.4
    chicken embryo fibroblasts preparation, 5.12.6–5.12.8
  titration by plaque assay, 5.12.5–5.12.6
Vectors
  for biosynthesis of polypeptides, 18.4.8
  database for BLASTN, TBLASTN, and TBLASTX, 2.5.5
  pTYB1 and sequence of cloning/expression region, 18.4.13 (fig.)
  λ vectors, for bacteriophage cDNA library, 19.3.1–19.3.2
Viscosity radius of dextran, molecular size calibration, 8.3.21
Viscous fingering, in GF chromatography, 8.3.11–8.3.12
Void fraction, and bed compression, GF chromatography, 8.3.28
Void marker, GF chromatography (recipe), 8.3.23
Void volume V_0
  column for GF chromatography, 8.3.10
  measuring, 8.3.12
  for protein fractionation, 8.3.27

W

Wang resin for polypeptide synthesis, 18.4.2 (table)
World Wide Web (WWW), sequence similarity via, UNIT 2.5

X

X-Cys motifs, for protein synthesis, 18.4.1
Xgal assay
  for *lacZ* gene activation, 19.2.9–19.2.10
  plate preparation (recipe), A.4L.3

Y

Yeast
  bait strain construction, 19.2.24
  colony hybridization, 19.2.30–19.2.31
  EGY48
    characteristics of, 19.2.5
    for interaction traps, 19.2.1
  growth and manipulation of, APPENDIX 4L
  growth media
    complete minimal (CM) dropout medium, A.4L.2
    minimal (synthetic dextrose medium), A.4L.1–A.4L.2
    minimal plates, A.4L.3
    rich (YPD), A.4L.1
    rich plates, A.4L.3
    specialty plates, A.4L.3
  interaction trap selection strains, 19.2.8 (table)
  mating procedure, library and bait strains, interactor hunt, 19.2.25–19.2.27
  strains of, storage and retrieval, A.4L.3–A.4L.4
  transformation with bait protein plasmid, 19.2.7–19.2.10

Z

Z buffer, recipe, A.4L.6

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Current Protocols in Protein Science

Supplement 16 **New Topics** **June 1999**

In this Supplement ...

☑ Characterizing Recombinant Proteins Using HPLC Gel Filtration and Mass Spectrometry UNIT 7.10

☑ Capillary Electrophoresis of Peptides and Proteins Using Isoelectric Buffers UNIT 10.13

☑ Theoretical Aspects of the Quantitative Characterization of Ligand Binding APPENDIX 5A

Coming soon ...

☑ Synthesis and Application of Peptide Dendrimers As Protein Mimetics

☑ Detection of Protein-Protein Interactions by Coprecipitation

☑ Metabolic Labeling with Amino Acids

☑ *New Chapter!* Quantitation of Protein Interactions

This supplement includes important new topics to bring your CPPS subscription up to date with the latest methodology. Also included is a reader response card for forwarding us your comments and suggestions. Please see next page for a full listing of contents and instructions for inserting pages.

For more detailed information about new and upcoming topics, visit the Current Protocols Home Page at *www.wiley.com/cp*.

If you have questions about your subscription, call Customer Service at 800-825-7550.

Routing List

After filing, you may wish to route this cover sheet to other Current Protocols users to keep them informed of the new topics.

FULL CONTENTS OF SUPPLEMENT 16

Instructions for Adding Pages to Core Manual

Full contents for Supplement 16 are listed below, with instructions for removing old pages and inserting new pages. Every page included with Supplement 16 is labeled as such beneath the page number.

Remove pages	Insert pages	Subject	Primary change/notes
VOLUME 1			
Main TOC: 1-6	Main TOC: 1-6	Main table of contents	Reflects new material in Chaps. 7, 10, and Appendices
vii-x	vii-xi	Contributors	Revised
Ch 2:1-2	Ch 2:1	Chapter 2 contents	Reflects revised *UNIT 2.5*
7.0.3-7.0.4	7.0.3-7.0.4	Chapter 7 introduction	Revision
—	7.10.1-7.10.15	Characterizing recombinant proteins using HPLC gel filtration and mass spectrometry	New *UNIT 7.10*
Ch 8:1-2	Ch 8:1-2	Chapter 8 contents	Reflects revised *UNIT 8.2*
—	10.13.1-10.13.16	Capillary electrophoresis of peptides and proteins using isoelectric buffers	New *UNIT 10.13*
VOLUME 2			
19.0.1	19.0.1	Chapter 19 introduction	Revision
Appendices: 3	Appendices: 3	Appendices	Reflects new *APPENDIX 5A*
—	A.5A.1-A.5A.40	Theoretical aspects of the quantitative characterization of ligand binding	New *APPENDIX 5A*
Suppliers app.: 1-17	Suppliers app.: 1-20	Suppliers appendix	Revision
Supp. 13, 14, & 15 index	—		Discard
Main index (43 pages)	Main index (51 pages)	New Main index	Entries covering core volumes through Supp. 16

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Table of Contents, Volumes 1 and 2

i Foreword

iii Preface

vii Contributors

1 Strategies of Protein Purification and Characterization

1.1 Overview of Protein Purification and Characterization

1.2 Strategies for Protein Purification

1.3 Protein Purification Flow Charts

2 Computational Analysis

2.1 Computational Methods for Protein Sequence Analysis

2.2 Hydrophobicity Profiles for Protein Sequence Analysis

2.3 Protein Secondary Structure Prediction

2.4 Internet Basics

2.5 Sequence Similarity Searching Using the BLAST Family of Programs

3 Detection and Assay Methods

3.1 Spectrophotometric Determination of Protein Concentration

3.2 Quantitative Amino Acid Analysis

3.3 In Vitro Radiolabeling of Peptides and Proteins

3.4 Assays for Total Protein

3.5 Kinetic Assay Methods

3.6 Biotinylation of Proteins in Solution and on Cell Surfaces

4 Extraction, Stabilization, and Concentration

4.1 Overview of Cell Fractionation

4.2 Purification of Organelles from Mammalian Cells

4.3 Subcellular Fractionation of Tissue Culture Cells

4.4 Desalting, Concentration, and Buffer Exchange by Dialysis and Ultrafiltration

4.5 Selective Precipitation of Proteins

BCU IASI CENTRAL UNIVERSITY LIBRARY

Copyright © 1999 by John Wiley & Sons, Inc.

5 Production of Recombinant Proteins

5.1 Production of Recombinant Proteins in *Escherichia coli*

5.2 Selection of *Escherichia coli* Expression Systems

5.3 Fermentation and Growth of *Escherichia coli* for Optimal Protein Production

5.4 Overview of the Baculovirus Expression System

5.5 Protein Expression in the Baculovirus System

5.6 Overview of Protein Expression in *Saccharomyces cerevisiae*

5.7 Overview of Protein Expression in *Pichia pastoris*

5.8 Culture of Yeast for the Production of Heterologous Proteins

5.9 Overview of Protein Expression by Mammalian Cells

5.10 Production of Recombinant Proteins in Mammalian Cells

5.11 Overview of the Vaccinia Virus Expression System

5.12 Preparation of Cell Cultures and Vaccinia Virus Stocks

5.13 Generation of Recombinant Vaccinia Viruses

5.14 Characterization of Recombinant Vaccinia Viruses and Their Products

5.15 Gene Expression Using the Vaccinia Virus/T7 RNA Polymerase Hybrid System

6 Purification of Recombinant Proteins

6.1 Overview of the Purification of Recombinant Proteins Produced in *Escherichia coli*

6.2 Preparation of Soluble Proteins from *Escherichia coli*

6.3 Preparation and Extraction of Insoluble (Inclusion-Body) Proteins from *Escherichia coli*

6.4 Overview of Protein Folding

6.5 Folding and Purification of Insoluble (Inclusion-Body) Proteins from *Escherichia coli*

6.6 Expression and Purification of GST Fusion Proteins

6.7 Expression and Purification of Thioredoxin Fusion Proteins

7 Characterization of Recombinant Proteins

7.1 Overview of the Characterization of Recombinant Proteins

7.2 Determining the Identity and Purity of Recombinant Proteins by UV Absorption Spectroscopy

7.3 Determining the Identity and Structure of Recombinant Proteins

7.4 Transverse Urea-Gradient Gel Electrophoresis

7.5 Analytical Ultracentrifugation

7.6 Determining the CD Spectrum of a Protein

7.7 Determining the Fluorescence Spectrum of a Protein

7.8 Light Scattering

7.9 Measuring Protein Thermostability by Differential Scanning Calorimetry

7.10 Characterizing Recombinant Proteins Using HPLC Gel Filtration and Mass Spectrometry

BCU IAS/CENTRAL UNIVERSITY LIBRARY

8 Conventional Chromatographic Separations

8.1 Overview of Conventional Chromatography
8.2 Ion-Exchange Chromatography
8.3 Gel-Filtration Chromatography
8.4 Hydrophobic-Interaction Chromatography
8.5 Chromatofocusing
8.6 Hydroxylapatite Chromatography

9 Affinity Purification

9.1 Lectin Affinity Chromatography
9.2 Dye Affinity Chromatography
9.3 Affinity Purification of Natural Ligands
9.4 Metal-Chelate Affinity Chromatography
9.5 Immunoaffinity Chromatography
9.6 Purification of Sequence-Specific DNA-Binding Proteins by Affinity Chromatography
9.7 Purification of DNA-Binding Proteins Using Biotin/Streptavidin Affinity Systems

10 Electrophoresis

10.1 One-Dimensional SDS Gel Electrophoresis of Proteins
10.2 One-Dimensional Isoelectric Focusing of Proteins in Slab Gels
10.3 One-Dimensional Electrophoresis Using Nondenaturing Conditions
10.4 Two-Dimensional Gel Electrophoresis
10.5 Protein Detection in Gels Using Fixation
10.6 Protein Detection in Gels Without Fixation
10.7 Electroblotting from Polyacrylamide Gels
10.8 Detection of Proteins on Blot Membranes
10.9 Capillary Electrophoresis of Proteins and Peptides
10.10 Immunoblot Detection
10.11 Autoradiography
10.12 Overview of Digital Electrophoresis Analysis
10.13 Capillary Electrophoresis of Peptides and Proteins Using Isoelectric Buffers

11 Chemical Analysis

11.1 Enzymatic Digestion of Proteins in Solution
11.2 Enzymatic Digestion of Proteins on PVDF Membranes
11.3 Digestion of Proteins in Gels for Sequence Analysis
11.4 Chemical Cleavage of Proteins in Solution
11.5 Chemical Cleavage of Proteins on Membranes

continued

BCU IASI / CENTRAL UNIVERSITY LIBRARY

11.6 Reversed-Phase Isolation of Peptides
11.7 Removal of N-Terminal Blocking Groups from Proteins
11.8 C-Terminal Sequence Analysis
11.9 Amino Acid Analysis
11.10 N-Terminal Sequence Analysis of Proteins and Peptides

12 Post-Translational Modification: Glycosylation

12.1 Overview of Glycoconjugate Analysis
12.2 Metabolic Radiolabeling of Animal Cell Glycoconjugates
12.3 Inhibition of N-Linked Glycosylation
12.4 Endoglycosidase and Glycoamidase Release of N-Linked Oligosaccharides
12.5 Detection of Glycophospholipid Anchors on Proteins

13 Post-Translational Modification: Phosphorylation and Phosphatases

13.1 Overview of Protein Phosphorylation
13.2 Labeling Cultured Cells with $^{32}P_i$ and Preparing Cell Lysates for Immunoprecipitation
13.3 Phosphoamino Acid Analysis
13.4 Detection of Phosphorylation by Immunological Techniques
13.5 Detection of Phosphorylation by Enzymatic Techniques
13.6 Production of Antibodies That Recognize Specific Tyrosine-Phosphorylated Peptides
13.7 Assays of Protein Kinases Using Exogenous Substrates
13.8 Permeabilization Strategies to Study Protein Phosphorylation

14 Post-Translational Modification: Specialized Applications

14.1 Analysis of Disulfide Bond Formation
14.2 Analysis of Protein Acylation
14.3 Analysis of Protein Prenylation and Carboxyl-Methylation

15 Chemical Modification of Proteins

15.1 Modification of Cysteine
15.2 Modification of Amino Acids

16 Mass Spectrometry

16.1 Overview of Peptide and Protein Analysis by Mass Spectrometry
16.2 Matrix-Assisted Laser Desorption/Ionization Time-of-Flight Mass Analysis of Peptides
16.3 Sample Preparation for MALDI Mass Analysis of Peptides and Proteins
16.4 In-Gel Digestion of Proteins for MALDI-MS Fingerprint Mapping

continued

BCU IASI / CENTRAL UNIVERSITY LIBRARY

16.5 Searching Sequence Databases Over the Internet: Protein Identification Using MS-Fit
16.6 Searching Sequence Databases Over the Internet: Protein Identification Using MS-Tag
16.7 Enzymatic Approaches for Obtaining Amino Acid Sequence: On-Target Ladder Sequencing

17 Structural Biology

17.1 Overview of Protein Structural and Functional Folds
17.2 Overview of Macromolecular Electron Microscopy
17.3 Principles of Macromolecular X-Ray Crystallography
17.4 Crystallization of Soluble Macromolecules

18 Preparation and Handling of Peptides

18.1 Introduction to Peptide Synthesis
18.2 Synthesis of Multiple Peptides on Plastic Pins
18.3 Synthetic Peptides for Production of Antibodies that Recognize Intact Proteins
18.4 Native Chemical Ligation of Polypeptides

19 Identification of Protein Interactions

19.1 Analysis of Protein-Protein Interactions
19.2 Interaction Trap/Two-Hybrid System to Identify Interacting Proteins
19.3 Phage-Based Expression Cloning to Identify Interacting Proteins

Appendices

A.1 Useful Data
- A Characteristics of Amino Acids
- B Commonly Used Detergents
- C Conversion Factors and Half-Life Information for Radioactivity

A.2 Laboratory Guidelines, Equipment, and Stock Solutions
- A Laboratory Safety
- B Safe Use of Radioisotopes
- C Centrifuges and Rotors
- D Standard Laboratory Equipment
- E Commonly Used Reagents

A.3 Commonly Used Techniques
- A Use of Protein Folding Reagents
- B Dialysis
- C Techniques for Mammalian Cell Tissue Culture
- D Importing Biological Materials
- E Silanizing Glassware
- F Protein Precipitation Using Ammonium Sulfate

continued

BCU IAS CENTRAL UNIVERSITY LIBRARY

A.4 Molecular Biology Techniques
A Media Preparation and Bacteriological Tools
B Growth in Liquid or Solid Media
C Preparation of Plasmid DNA
D Introduction of Plasmid DNA into Cells
E Purification and Concentration of DNA from Aqueous Solutions
F Agarose Gel Electrophoresis
G Southern Blotting
H Hybridization Analysis of DNA Blots
I Digestion of DNA with Restriction Endonucleases
J The Polymerase Chain Reaction
K Quantitation of Nucleic Acids with Absorption Spectroscopy
L Growth and Manipulation of Yeast
A.5 Biophysical Methods: Data Analysis
A Theoretical Aspects of the Quantitative Characterization of Ligand Binding

chromatography with on-line light scattering detectors are especially useful for characterizing proteins and glycoproteins (for review see Wen et al., 1996). *UNIT 7.8* provides an overview of the various light-scattering methods used to characterize proteins and macromolecular complexes. It should be noted that this method, like analytical centrifugation, provides direct molecular weight information without the use of calibration standards or models.

Circular dichroism and fluorescence spectroscopy are popular methods for determining protein conformation. Basic protocols for determining the circular dichroic spectra of proteins are described in *UNIT 7.6* and for determining the fluorescence spectra in *UNIT 7.7*. Circular dichroism and fluorescence spectroscopy are similar to most other spectroscopic methods in that careful interpretation of the data is required together with an understanding of the limitations and pitfalls of the method. These points are emphasized throughout these units.

Differential scanning calorimetry (DSC), described in *UNIT 7.9*, is an instrumental method used to measure heat energy uptake (heat capacity) in proteins undergoing thermal denaturation. This is accomplished by varying the temperature of a dissolved protein sample and measuring the difference in heat generated by the protein compared to a reference cell that contains solvent alone. This heat difference is related to the conformational energy of the protein molecule. In practice, when proteins undergo thermal denaturation, typically at 40° to 80°C, there is usually heat generated (i.e., it is an exothermic process); this heat can be very accurately measured by modern DSC instruments. The unit discusses the theoretical background of the method and details methods for actually performing DSC. For background on basic thermodynamic principles consult, for example, Tinco et al. (1995), and for overview of DSC applications in biotechnology see Chowdhry and Cole (1989). The Internet sites of the various instrument manufacturers are also useful sources of information.

Gel filtration is a technically simple method that is nonetheless one of the most powerful available for characterizing recombinant proteins. Working in an analytical mode using modern automated equipment, information on protein purity, conformation, and physical homogeneity can be obtained within a very short time. When the analysis is combined with mass spectroscopy, the gel filtration chromatogram can usually be fully interpreted to determine the chemical identity of all the peaks. *UNIT 7.10* details the complementary use of HPLC gel filtration and mass spectroscopy to analyze recombinant proteins.

CONFORMATIONAL ANALYSIS OF RECOMBINANT-PRODUCED PROTEINS

The assays for many protein functions, for example in the case of cytokines, can be time consuming and of relatively low precision. As proteins depend for their function on the correct 3D fold of the polypeptide chain, demonstration that the conformation of the recombinant protein is the same as that of the authentic protein should provide a more convenient means of characterizing the product. The methods described in *UNITS 7.4, 7.6 & 7.7*, although providing average structural information only, as compared with X-ray crystallography or NMR, are sensitive indicators of conformation and conformational change and, as such, can provide a highly specific "fingerprint" of a protein. Such conformational analysis will follow assurance of chemical authenticity and homogeneity, as described in *UNITS 7.1-7.3* (and elsewhere in the book). Urea gradient gel electrophoresis (*UNIT 7.4*) is a hydrodynamic technique that monitors the degree of compactness of the protein. It allows unfolding and refolding to be studied, leading to characterization of the protein in terms of its stability and kinetics. Near-UV circular dichroism (CD) results in spectra that are characteristic of the polar asymmetry of the environments of the aromatic

BOSTON BIOMEDICAL CENTER - UNIVERSITY LIBRARY

residues, mainly tryptophan and tyrosine. Far-UV CD monitors the polypeptide backbone conformation, and hence, the secondary structure. Fluorescence spectra are determined chiefly by the polarity of the environment of the tryptophan and tyrosine residues and their interactions.The four techniques thus provide different, but complementary, fingerprints of the protein conformation that provide a high degree of assurance of nativeness within a few hours. For quality assurance of the native conformation and for general characterization, it is important to employ as broad a range of the available techniques as possible.

Besides confirming the nativeness of the folded conformation of a sample of a protein that has already been characterized, either as the previously produced recombinant protein or as the authentic protein, the techniques described here offer a rapid means of obtaining structural and dynamic information, together with estimates of the stability of the protein.

Characterizing Recombinant Proteins Using HPLC Gel Filtration and Mass Spectrometry

It is essential to determine the identity, sequence integrity, purity, oligomeric state, and conformational integrity of a protein before structural or functional studies are carried out. This is true for proteins isolated from any source, but is particularly important for recombinant proteins, which are subject to several problems associated with their artificial overexpression in a heterologous host. These problems include expression in a denatured state, aggregation, mutations, incorrect translation (e.g., stop codon readthrough), incorrect proteolytic processing, and unwanted post-translational modifications. Often these problems cannot be detected using SDS-PAGE. Fortunately, most sources of heterogeneity in recombinant proteins can be identified by a preliminary analysis of the sample using a combination of analytical high-performance liquid chromatography/fast protein liquid chromatography (HPLC/FPLC) and matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS). Analytical gel filtration is used to detect and quantify contaminants in the sample (including protein aggregates), and can give an approximate measure of the protein size in solution (Stokes radius). Mass spectrometry is then used to determine the molecular weight of the protein to within a few daltons, which enables the detection and identification of incorrect sequence length and most chemical modifications of amino acid side chains. Apart from detecting unwanted modifications to the protein of interest, HPLC and mass spectrometry can be used to help characterize post-translational modifications such as glycosylation (see Chapter 12).

In this unit, analytical HPLC gel filtration is used to characterize a purified recombinant protein sample in the Basic Protocol. A method for determining the Stokes radius of a protein using HPLC is described in Support Protocol 1. MALDI-MS is used to characterize a protein sample in Support Protocol 2.

NOTE: Milli-Q-purified or equivalent quality water should be used for all buffers.

STRATEGIC PLANNING

Selecting Column Type and Size

The first step in planning a size-exclusion fractionation is selecting the type of column to be used. Several factors need to be considered. Most importantly, the molecular weight of the recombinant proteins to be analyzed should fall within the fractionation range of the column, which is determined by the pore size of the particles. The fractionation range should be large enough to encompass the molecular weights of all species to be separated, and the protein of interest should be near the midpoint of the fractionation range. The fractionation range may be increased by placing two columns with different pore sizes in series.

Further selection of the column depends upon several related factors: the required resolution, the sample volume, and the desired run time. For analytical gel filtration, the aim is to maximize resolution while minimizing run time. Resolution is affected by the particle size and size distribution, as well as the column length and the flow rate (for a detailed discussion, see *UNITS 8.1 & 8.3*, or Neue, 1997). Columns with small, rigid, well-defined particles (<15 µm diameter) show the best resolution while allowing fast flow rates and therefore short run times (12 to 60 min). Table 7.10.1 lists several common commercial prepacked columns that feature small particle sizes and good resolution. The disadvantage of these columns is that the small particle sizes lead to high back pressures, requiring an isocratic chromatography system that can operate at moderate pressure (FPLC; 200 to 600 psi) or preferably higher pressure (HPLC; >500 psi). Resolution may

TSU IASI / CENTRAL UNIVERSITY LIBRARY

be further enhanced by increasing the length of the column; if a longer column is not available, two columns may be placed in series to achieve the same effect. Low-pressure gel filtration columns with softer, larger particles are generally less expensive and allow larger protein loads, but require lower flow rates, which markedly increases the run time for the separation while providing reduced resolution even at low flow rates.

If it is necessary to scale up an analytical separation, the sample volume will determine the size of the column required—the larger the sample volume and amount of protein to be separated, the greater the column volume needed. One option is to increase the length of the column; for example, a 60-cm column has twice the sample volume capacity of a 30-cm column, with little loss of resolution. Increasing the diameter of the column will also increase the maximum load in proportion to the square of the increase in diameter. Table 7.10.1 lists prepacked columns for both preparative work (i.d. = 21.5 or 55 mm) and analytical work (i.d. ≤ 10 mm).

Another factor to consider when selecting a column is the potential for interactions between the sample and the column. For example, silica-based columns are available in the smallest particle sizes and can be operated at higher pressures compared to agarose gels; however, some adsorption can occur due to electrostatic interactions with unmodified silanol groups. Usually these effects can be minimized by maintaining at least a physiological ionic strength. Stainless steel columns can withstand high back pressures, but also have drawbacks. For example, some samples might interact with the metal surfaces (especially stainless steel end frits) and common buffer components (e.g., halogens such as chloride) can react with incompletely passivated stainless steel surfaces such as the compression screws. For samples or buffer systems that are incompatible with stainless steel, glass columns should be used.

Selecting Instrument Type

An isocratic (one pump, one buffer) HPLC or FPLC system is required for the columns described in this unit. Selection of an appropriate chromatography system involves two major decisions: operating pressure range and whether or not biocompatibility is needed. FPLC, HPLC, and biocompatible systems are appropriate for different types of applications. An FPLC system is used to run columns that require moderate back pressure (typically 50 to 600 psi). An HPLC system is used to run columns with higher back pressures (typically >500 psi). Biocompatible systems are available for operation in a variety of pressure ranges and are used in cases where the protein of interest may be adversely affected by trace metal ions that could exist with a system containing stainless steel. Biocompatibility is a heterogeneously applied term, generally assumed to mean a system with few or no stainless steel components. The importance of biocompatibility for most protein applications has not been clearly established.

Many companies sell integrated computer-controlled systems that consist of reliable pumps, an injector, a UV detector, a fraction collector, and a computer output for data collection and manipulation. Of course, a dual-pump HPLC or FPLC system may be used by utilizing only one of the pumps. It is most critical to have a pumping system that can deliver a constant flow rate in the desired range, which is typically 0.1 to 1.5 ml/min for analytical columns and up to 5 ml/min for preparative columns. Because of the small number of samples typically analyzed, an autosampler is not necessary. However, it is important to have a computer integrated with the injector to ensure precise starting points for sample injection. While most binary HPLC and FPLC systems are relatively expensive, there are less expensive alternatives, such as integrated isocratic systems that cover the required pressure range (e.g., 0 to 2500 psi) and cost under $10,000 (e.g., D-Star Instruments Integrated Isocratic HPLC system, available through Thomas Scientific).

BOSTON COLLEGE UNIVERSITY LIBRARY

Selecting Appropriate Buffers

The buffer selected for gel filtration should be optimized for protein stability. Highly hydrophobic or membrane proteins, for example, require a nondenaturing detergent in the buffer (see next section). Silica-based resins are not stable above pH 7.5, and stainless steel columns should typically not be used with halogens. Buffer type and strength may affect resolution and mass recovery. The ionic strength of the buffer is also important. In high–ionic strength buffers (>1 M), hydrophobic interactions between the protein and the resin may occur, while at low ionic strength (<0.1 M), ionic interactions may occur.

Analysis of Membrane Proteins in Detergents

The separation of membrane proteins in the presence of detergents (typically a nonionic or zwitterionic detergent) is the same in principle as separation in aqueous solutions. However, in the presence of detergent, the apparent size of the protein will probably increase due to detergent binding to the protein. For this reason, the fractionation range of gel filtration columns specified for water-soluble proteins will not apply to detergent-solubilized proteins (Schagger, 1994). Accurate size determination is not feasible in the presence of detergents, since membrane proteins will bind detergent molecules and/or interact with detergent micelles to differing degrees.

The procedure for gel filtration in the presence of detergent is essentially as described in the Basic Protocol, with a few additional factors to take into account. First, the protein sample should be equilibrated with the detergent prior to the run. Detergents with a low critical micelle concentration (CMC) do not dialyze well, so the detergent can be added directly to the sample, or a desalting column can be used for buffer exchange. The choice of detergent is another important consideration. If the protein elution profile is to be detected via UV absorbance, for example, the detergent needs to be transparent at the wavelength selected (for example, detergents containing aromatic ring systems, e.g., Triton, absorb strongly at 280 nm), unless the concentration of detergent can be kept low enough to keep the absorbance signal within the linear range of the UV detector. However, the gel filtration buffer should contain detergent at a concentration well above the CMC (i.e., ≥4×) to prevent association of membrane proteins (Schagger, 1994). The micelle size is also important, as large micelles will change the elution behavior of proteins more than small micelles, and may be harder to separate from the protein of interest.

A common problem in gel filtration of membrane proteins is adsorption of protein to the resin or the column. The extent of this problem depends upon the detergent type and concentration, as well as the resin type and column hardware. Unfortunately, predicting the column and detergent that will minimize adsorptive losses is difficult, and a trial-and-error approach may be needed to find the optimum combination.

BASIC PROTOCOL

HPLC ANALYSIS OF RECOMBINANT PROTEINS

This protocol describes analytical HPLC gel filtration of soluble recombinant proteins (refer to *UNITS 8.1 & 8.3* for a complete description of gel filtration chromatography). Analytical HPLC is used to evaluate sample heterogeneity and quantify sample components. For example, HPLC may be used to monitor the proteolytic cleavage of a fusion protein (Fig. 7.10.1), to separate two or more oligomers, or to determine the amount of aggregate or other contaminates in a sample. Although the protocol is written for HPLC systems, FPLC and HPLC are largely interchangeable (see Strategic Planning), and either can be used.

As analytical HPLC is often used to compare different preparations of a recombinant protein, to monitor the homogeneity of a sample over time, or to compare a recombinant

FSU IAS / CENTRAL UNIVERSITY LIBRARY

protein with standards, accurate and reproducible determination of retention time is critical. For this reason it is important to use high-precision chromatography pumps that provide a constant, accurate flow rate. It is also important that the column packing be in good condition and maintained at a constant temperature; typically 4°C is used to minimize potential proteolysis of the protein. This can be accomplished by placing either the column or the entire chromatography system in a cold cabinet.

Materials

Gel filtration buffer (see recipe)
Protein standard (e.g., Bio-Rad gel filtration standard)
Protein sample
0.05% (w/v) sodium azide or 20% (v/v) ethanol

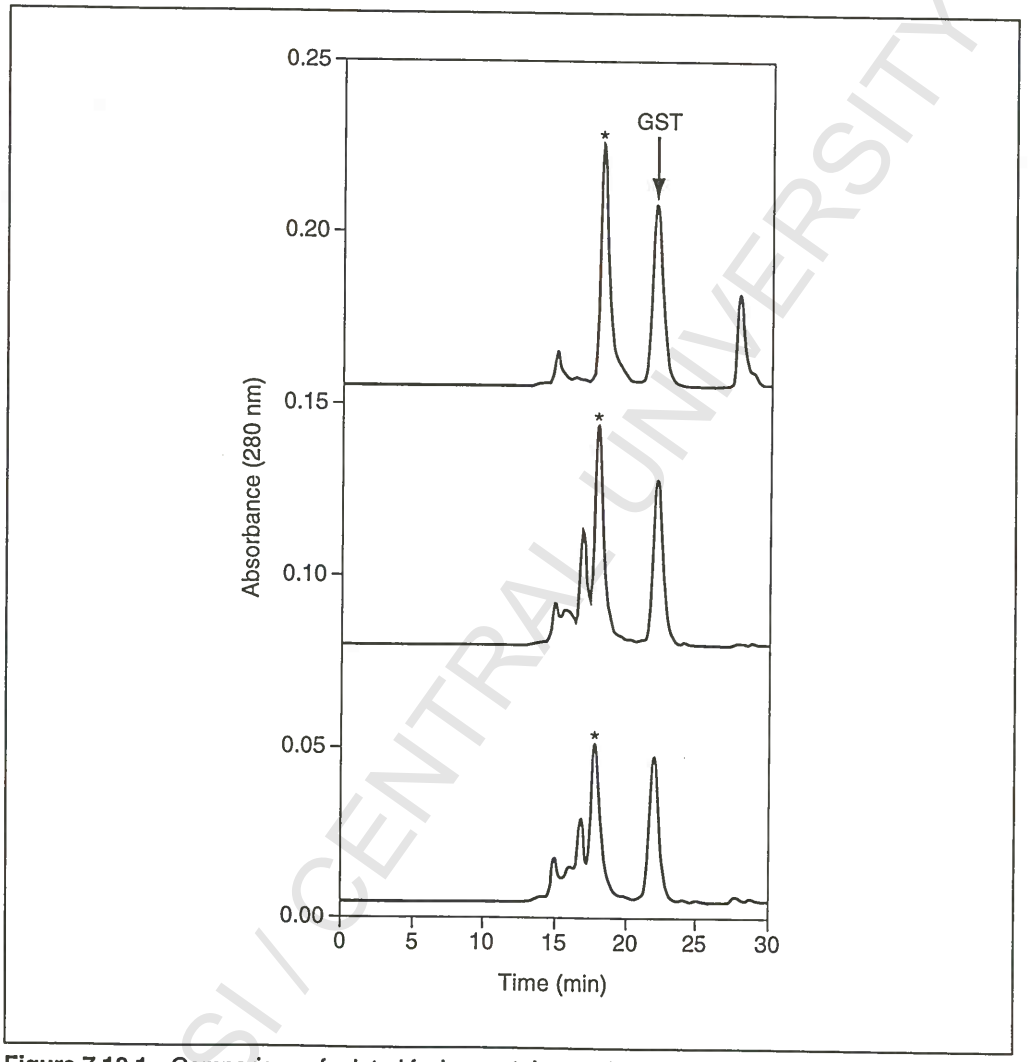

Figure 7.10.1 Comparison of related fusion proteins analyzed immediately after protease cleavage using analytical HPLC gel filtration to evaluate potential self-aggregation. The top panel shows 100 µg of the wild-type 52-kDa recombinant protein, and the lower panels show two different mutants. The asterisk indicates the retention time of the monomeric proteins. The elution position of the glutathione-S-transferase (GST) moiety is also indicated. Peaks eluting earlier than the monomeric form of the protein are self-aggregates. These results show that the mutants, but not the wild type, rapidly aggregate during protease digestion. When monomeric forms of the mutants were isolated by preparative HPLC gel filtration and reanalyzed by analytical gel filtration, a substantial increase in aggregation occurred in a concentration- and time-dependent manner (data not shown).

BRANDEIS / CENTRAL UNIVERSITY LIBRARY

Isocratic liquid chromatography system (HPLC or FPLC)
Prepacked HPLC or FPLC column (Table 7.10.1)
0.2-μm filters

1. Select an appropriate column for the type of proteins to be analyzed. Refer to Strategic Planning and Table 7.10.1 for a listing of prepacked analytical HPLC columns.
2. Prepare an isocratic liquid chromatography system as in Basic Protocol 1 of *UNIT 8.3*, steps 14 to 16 (also see Strategic Planning of this unit).

   It is desirable to have an HPLC UV detector in line with outputs to both a strip chart recorder and to a computer for peak quantification.
3. Filter gel filtration buffer that is compatible with both the column and the sample, using a 0.2-μm filter to degas and remove any small particles that may clog the column frit.

   Refer to the manufacturer's recommendations for column-compatible buffers. The column buffer does not need to be identical to the buffer of the injected sample, as gel filtration can also be used to exchange buffers; however, the sample should be tested with the column buffer to ensure that no precipitate occurs when the sample enters the column.

   If bacteriostatic agents are not used, buffer should be filtered daily.
4. Equilibrate the column with three column volumes of gel filtration buffer.

   Do not exceed the manufacturer's recommended flow rates or pressure limits. If operating at low temperatures, it may be necessary to decrease the flow rate as the viscosity of the buffer may increase, generating higher back pressures.
5. Pass a protein standard through a protein-compatible 0.2-μm filter or centrifuge at 10,000 × *g* for 10 min to remove particulate matter.
6. Rinse the sample application loop with gel filtration buffer and evaluate the performance of the column by injecting the protein standard.

   Figure 7.10.2 shows chromatograms obtained with columns showing optimal (upper panel) and poor performance (lower panel). Note the reduced peak heights, increased peak widths, and decreased separation between peaks in the lower chromatogram.
7. Pass a protein sample through a 0.2-μm filter or centrifuge at 10,000 × *g* for 10 min to remove particles.
8. Rinse the sample application loop again and inject an aliquot of the recombinant protein to be analyzed.

   The lower limit of protein concentration is determined by the sensitivity of the detector used, while the upper limit is influenced by multiple factors including sample viscosity, potential nonideal behavior of the sample at high concentrations (e.g., aggregation), and degradation of resolution between adjacent peaks as protein loads increase. For optimum resolution, sample volumes should be ≤1% of the total column volume (column volume [ml] = $\pi r^2 l$, where radius [r] and length [l] are in cm). For initial analytical separations, a sample volume of ~0.5% of the column volume can generally be used, with a total protein concentration of ~0.5 to 1.0 mg/ml.

   Figure 7.10.3 shows a typical analysis of a 55-kDa recombinant protein by SDS-PAGE, HPLC, and MALDI-MS.
9. *Optional:* Collect fractions of the eluting proteins.

   Collection of fractions during a gel filtration separation allows subsequent identification of individual peaks with other methods such as MALDI-MS (see Support Protocol 2 and Fig. 7.10.5C), SDS-PAGE (UNIT 10.1 and Fig. 7.10.5B), immunoblotting (UNIT 10.10), or N-terminal sequencing (UNIT 11.10). However, it should be noted that because the amount of protein typically loaded on an analytical HPLC column is small, and proteins are diluted

PSU IASL / CELTRA UNIVERSITY LIBRARY

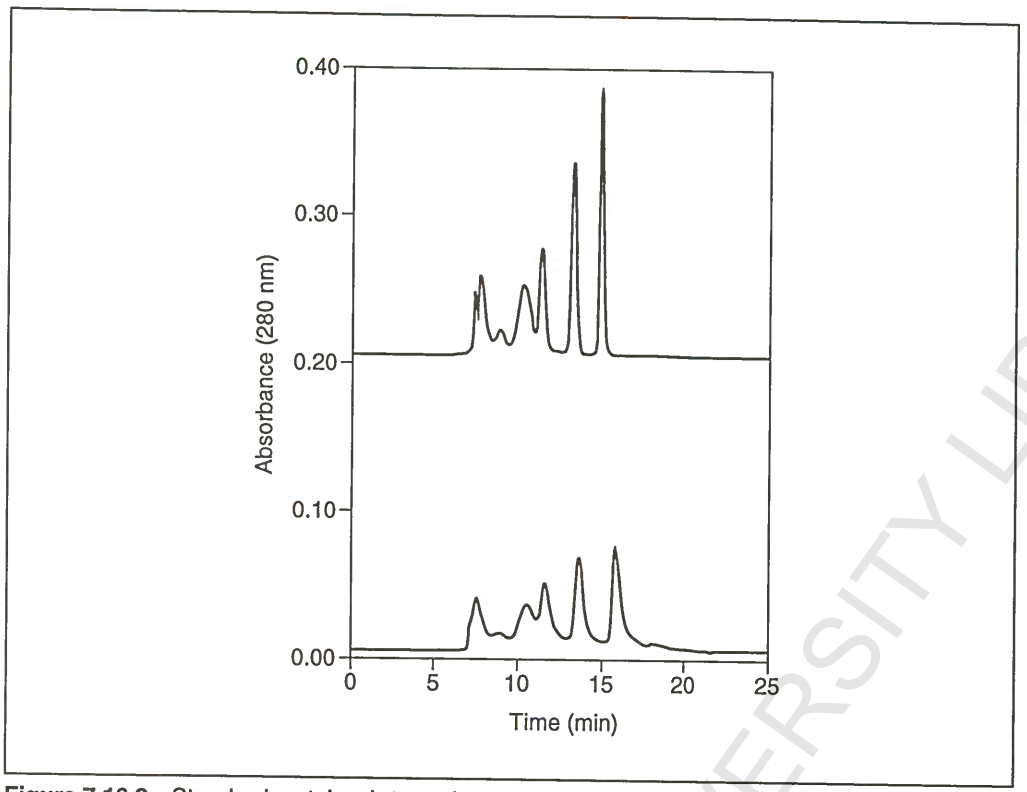

Figure 7.10.2 Standard protein mix to evaluate column performance. A comparison between new (upper panel) and old (lower panel) TSK G3000SW$_{XL}$ (TosoHaas) columns. In this case, the decreased resolution of the old column was primarily attributed to a void that had formed at the top of the column (see Troubleshooting).

during the separation, the protein yield and/or concentration may not be high enough for some forms of analysis. In some cases the fractions may be pooled and/or concentrated prior to analysis, otherwise the separation may have to be scaled up (see Strategic Planning). If collecting fractions, it is a good idea to collect through the entire run time of the separation, using fraction volumes that will provide at least four to six fractions across a typical peak (this can be estimated from the average peak widths of standard proteins).

10. Store column in a solution containing a bacteriostat such as 0.05% sodium azide or 20% ethanol. Refer to the manufacturer's recommendations regarding column storage.

DETERMINATION OF STOKES RADIUS BY HPLC GEL FILTRATION

SUPPORT PROTOCOL 1

This protocol describes the use of HPLC gel filtration to rapidly determine the Stokes radius of proteins (also see *UNIT 8.3*, Basic Protocol 3). Protein standards may be ordered individually or as part of a kit. Table 8.3.8 provides a list of commercially available standards. It is important to note that a Stokes radius is a measure of molecular size and not molecular mass; effectively, it is the radius of an equivalent hydrated sphere (Cantor and Schimmel, 1980). Thus, an approximate molecular mass may be obtained only when the protein of interest and the protein standards that are used in calibration have the same shape. As most standards are roughly spherical, the protein of interest should also be spherical. A better estimate of molecular mass (independent of shape) may be calculated from the Stokes radius combined with a sedimentation coefficient, which can be obtained using analytical ultracentrifugation or sucrose gradients (Seigel and Monty, 1966; *UNIT 7.5*).

1. Select a column of appropriate fractionation range for samples of interest and equilibrate the column in a compatible gel filtration buffer (see Basic Protocol, steps 1 to 4).

BOSTON CENTRAL UNIVERSITY LIBRARY

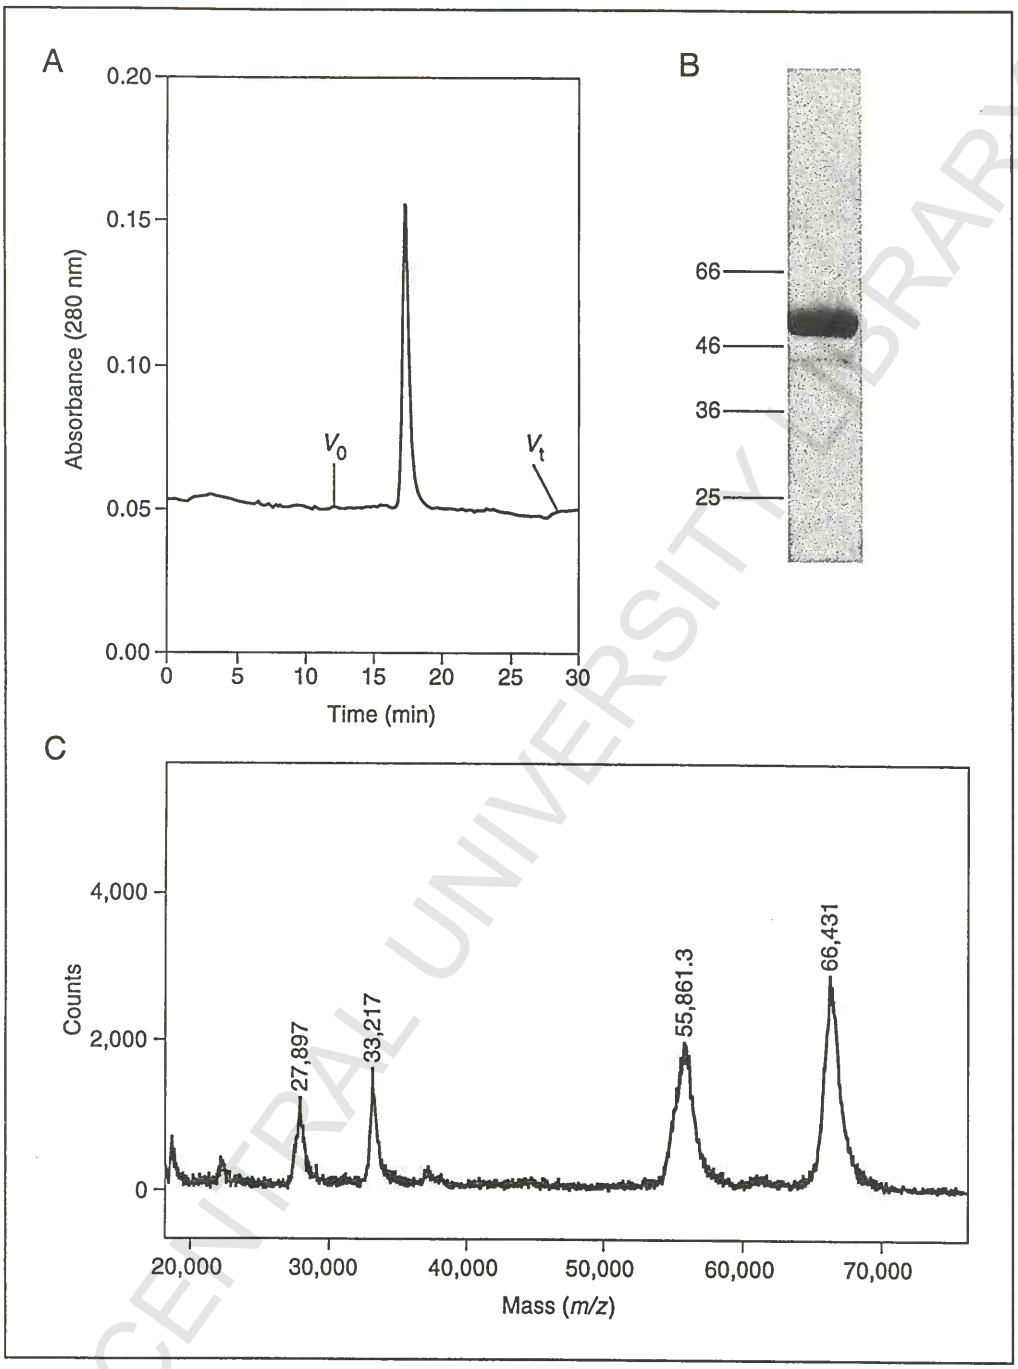

Figure 7.10.3 Analysis of a purified recombinant protein by HPLC gel filtration, SDS-PAGE, and mass spectrometry. (**A**) HPLC chromatograph of an α-actinin recombinant (25 µg injected). (**B**) SDS-PAGE Coomassie blue–stained gel showing the α-actinin recombinant. (**C**) Mass spectra of α-actinin recombinant protein. The apparent mass from SDS-PAGE is close to the expected mass. The HPLC chromatograph shows a single species, which migrates near the midpoint of the fractionation range, indicated by the void volume (V_0) and the total column volume (V_t). However, when mass analysis was performed, the actual mass observed ($[M + H]^+$ = 55,861.3 or [M] = 55,860.3) was 738 Da larger then the sequence molecular mass, corresponding to a readthrough of the insert stop codon. Instead, the sequence terminated at the in-frame stop codon in the cloning vector. The peak at 66,431 is the single protonated form of BSA, an internal standard. The peaks at 27,897 and 33,217 correspond to the double-protonated species of the recombinant and standard, respectively.

FSU IAS - CENTRAL UNIVERSITY LIBRARY

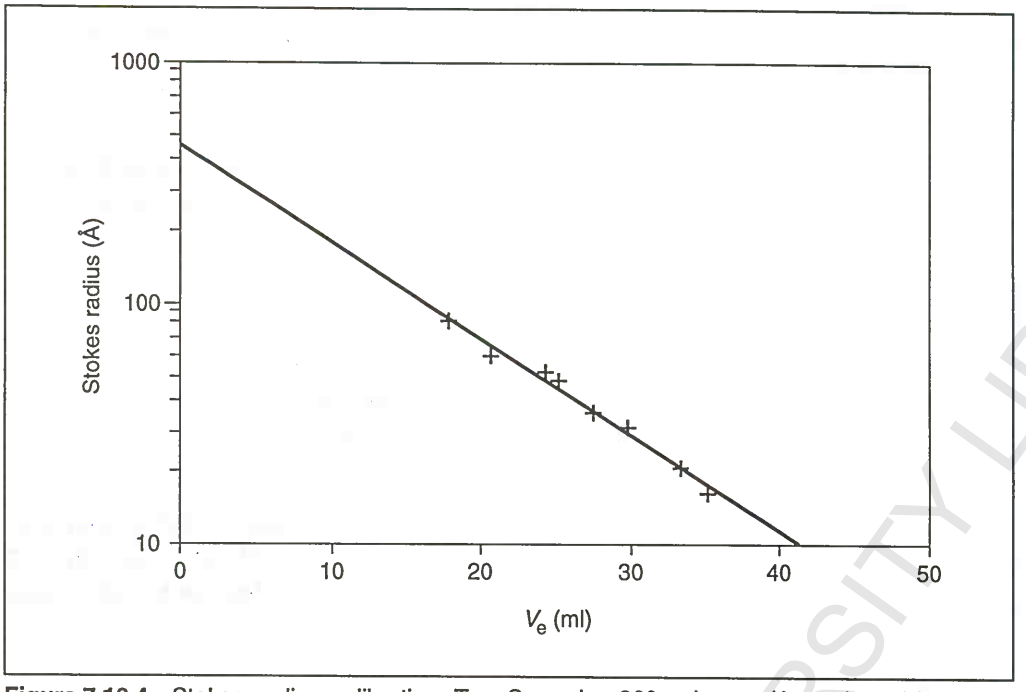

Figure 7.10.4 Stokes radius calibration. Two Superdex 200 columns (Amersham Pharmacia Biotech) were connected in series and run at a flow rate of 0.5 ml/min in PBS, pH 7.4, containing EDTA, phenylmethylsulfonyl fluoride, and sodium azide. Individual protein standards from the Amersham Pharmacia Biotech high- and low-molecular-weight gel filtration kits were prepared at a concentration of 1 to 5 mg/ml in gel filtration buffer. A total of 50 µg of each standard was injected. Samples included: ribonuclease A (16.4 Å), chymotrypsinogen A (20.9 Å), ovalbumin (30.5 Å), albumin (35.5 Å), aldolase (48.1 Å), catalase (52.2 Å), ferritin (61.0 Å), and thyroglobulin (85.0 Å). The retention time was multiplied by the flow rate (measured as 0.45 ml/min) to determine the elution volume (V_e), which was plotted verses the log of the known Stokes radii (R_s). The equation for the fitted line is $\log R_s = -0.04 V_e + 2.65$. This equation can then be used to determine the Stokes radius of an unknown, by injecting a small amount of the sample, determining V_e, and solving the equation for R_s.

2. Dissolve individual protein standards to a concentration of 1 to 5 mg/ml in gel filtration buffer. Pass through a protein-compatible 0.2-µm filter or centrifuge at 10,000 × *g* for 10 min to remove particulate matter.

   Protein standards can be mixed together to save time and reduce the number of injections; however, some proteins may interact and affect the elution of other proteins in the mix.

3. Inject each protein standard or the protein standard mixture onto the column. Rinse the sample application loop with buffer prior to each injection.

   For accurate comparison of the standard and sample retention times, the volume of the protein standard injected onto the column should be the same as that of the sample to be tested.

4. Determine the elution volume (V_e) of each standard by multiplying the retention time by the flow rate.

   Because pump performance will vary on most systems as piston seals wear, it is a good idea to check the actual flow rate by measuring the precise time required for 10 ml of eluant to be collected in a 10-ml graduated cylinder or volumetric flask.

5. Construct a graph plotting the log of the known Stokes radius (R_s) versus elution volume for each standard.

   Figure 7.10.4 shows a graph of $\log R_s$ versus V_e for a series of protein standards run on a Superdex 200 column.

B. C. U. „M. EMINESCU" IAŞI
CHIMIE

BCU IASI / CENTRAL UNIVERSITY LIBRARY

6. Fit the points with a straight line. Determine the slope (a) and y offset (b) of the line.

   Most graphing or spreadsheet programs may be used to perform linear regression analysis on the data points, giving the slope and offset of the fitted line.

7. Inject protein samples with unknown Stokes radii onto the same column. Calculate V_e and use the equation $\log R_s = aV_e + b$ to determine the Stokes radius of each unknown (see Fig. 7.10.4).

SUPPORT PROTOCOL 2

MALDI-MS ANALYSIS OF RECOMBINANT PROTEINS

The following protocol describes a basic method for MALDI-MS analysis of proteins carried out on a Voyager RP spectrometer (PerSeptive BioSystems). See *UNITS 16.1-16.3* or Beavis and Chait (1996) for a more detailed discussion of MALDI-MS theory and methods.

Two matrices are commonly used for recombinant proteins: α-cyano-4-hydroxycinnamic acid (for proteins <20 kDa) and sinapinic acid (for proteins >20 kDa), each in 33% acetonitrile/0.1% trifluoroacetic acid. The optimum matrix may have to be determined empirically for each sample.

Materials

1 to 10 pmol/µl HPLC-purified protein sample of interest (see Basic Protocol)
MALDI-MS-compatible buffer (e.g., 10 mM ammonium bicarbonate, pH 8)
Molecular weight standards
Saturated matrix solution (see recipe)
Sample target (e.g., gold or stainless steel plate)
Matrix-assisted laser desorption/ionization (MALDI) mass spectrometer (Voyager RP, PerSeptive BioSystems)

1. *Optional:* Dialyze an HPLC-purified protein sample into a MALDI-MS-compatible buffer.

   This step removes buffer components that may interfere with ionization or crystal formation. See Table 16.2.1 for tolerance limits of buffer components. Sodium azide, which is typically used in HPLC gel filtration buffers as a bacteriostatic reagent, is particularly problematic if not removed by dialysis, as it causes strong signal suppression.

   Very small samples (<300 µl) can be dialyzed in a microcentrifuge tube (Overall, 1987).

2. Dilute sample to a concentration of 1 to 5 pmol/µl with water or MALDI-MS buffer.

3. Select and prepare molecular weight standards.

   Two mass peaks are typically used to calibrate the mass spectrometer; these can be the singly and doubly charged species of a single standard, such as protein A, or two different protein standards. Ideally, the molecular weight of the standards should bracket the expected masses of the sample. See Table 7.10.2 for a list of typical molecular weight standards. The most accurate calibration is obtained when the standards are included in the sample of interest (internal calibration). However, the standard may suppress ionization of the recombinant protein, in which case the ratios of standards and sample must be adjusted empirically or an external calibration must be used.

4. Apply 0.5 µl saturated matrix solution to a sample target and allow to air dry. Apply 0.5 µl protein sample onto the dried matrix and allow to dry.

   Alternatively, mix 2 µl matrix with 2 µl sample in a microcentrifuge tube, apply 1 µl to the sample target, and allow to air dry.

CSU IASL CENTRAL UNIVERSITY LIBRARY

Table 7.10.2 Common Molecular Weight Standards for MALDI-MS of Proteins

Standard	Molecular weight (Da)	Concentration (pmol/μl)	Matrix
Bradykinin	1061.2	1	HCCA[a]
Insulin B	3496.9	1	HCCA
Insulin	5734.6	2-4	HCCA
Ubiquitin	8565.9	1-2	HCCA
Cytochrome *c*	12231.9	1-2	HCCA
α-Lactalbumin	14071.1	1-2	HCCA
Trypsin inhibitor A	20091.7	1-2	Either
α-Chymotrypsin	25234.7	1-2	Either
Ovalbumin	44401.0	3-5	Sinapinic acid
Protein A	44614.0	3-5	Sinapinic acid
BSA	66341.0	3-5	Sinapinic acid

[a]HCCA, α-cyano-4-hydroxycinnamic acid.

5. Insert sample target into a MALDI mass spectrometer and follow the manufacturer's procedure for obtaining a spectrum.
6. Compare the mass obtained with that expected from the amino acid sequence of the recombinant protein.

The masses should agree to within ~0.1% when an external standard is used, and ~0.03% using an internal standard. If this is not the case, or if additional peaks are present, there may be some modification of the protein. Table 7.10.3 lists some common modifications seen with recombinant proteins. Figure 7.10.5 shows typical MALDI-MS results.

Table 7.10.3 Interpreting Mass Spectra of Recombinant Proteins

Problem/change	Comment	Typical mass change
Stop codon readthrough (Fig. 7.10.3)	Stop codon in the construct is missed; translation continues until the next stop codon, often in the vector	+50 to 1000
Disulfide adduct	Disulfide bond formed between a reducing agent and a highly reactive cysteine in the recombinant protein	+76 (2-mercaptoethanol) +119 (dithiothreitol) +305 (glutathione)
Disulfide dimer	Formed between two reactive cysteines	2× expected mass
Protease degradation	For example, due to contaminating proteases, or secondary cleavage sites for proteases used to cleave fusion protein	Variable size reduction
Incomplete removal of tag sequences	For example, His tag (~6 His) or Flag sequence	Increased mass should equal calculated tag sequence
Post-translational modifications (e.g., glycosylation; Fig. 7.10.5C)	Only in eukaryotic expression systems; glycosylation usually gives broad or multiple peaks	Variable (+ ≥300)
Removal of initiation Met residue		−131

BOKHARI / CENTRAL UNIVERSITY LIBRARY

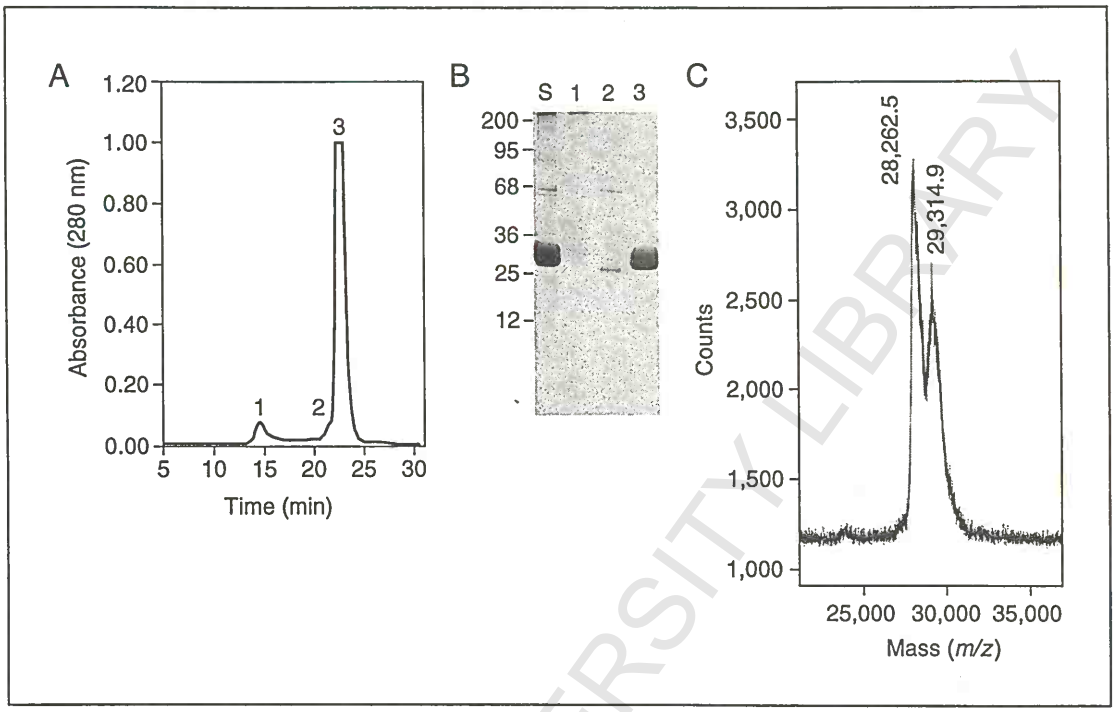

Figure 7.10.5 Identifying post-translational modifications using MALDI-MS. (**A**) HPLC chromatograph of a recombinant extracellular domain expressed in *Sf*9 insect cells. The recombinant protein (peak 3) is effectively separated from high-molecular-weight contaminants (peaks 1 and 2). (**B**) SDS-PAGE of the sample before gel filtration (lane S), and fractions taken from HPLC peaks 1 to 3 (lanes 1 to 3). (**C**) MALDI mass spectrum of the purified extracellular domain from peak 3. Two broad peaks are detected, with molecular masses 0.6 to 1.7 kDa greater than the molecular mass calculated from the sequence (27,531 Da), indicating heterogeneous glycosylation of the protein. The sequence mass was calculated after determining the site of signal peptide cleavage using N-terminal sequence analysis of the intact recombinant.

REAGENTS AND SOLUTIONS

Use Milli-Q-purified water or equivalent for the preparation of all buffers. For common stock solutions, see ***APPENDIX 2E****; for suppliers, see* ***SUPPLIERS APPENDIX****.*

Gel filtration buffer

PBS (*APPENDIX 2E*) or other buffer compatible with both the column and sample. Protease inhibitors (e.g., 1 mM EDTA, 0.15 mM phenylmethylsulfonyl fluoride) as well as a bacteriostat (0.05 % sodium azide) may also be added to the buffer. A reducing agent (2-mercaptoethanol, dithiothreitol, or tris(2-carboxyethyl)phosphine hydrochloride [TCEP·Cl]) may also be included to prevent proteins containing reactive cysteines from forming disulfide linkages.

Buffers should be degassed and made fresh each week unless antimicrobial agents have been added, in which case it may be used for up to one month.

Saturated matrix solution

Prepare 10 mg/ml matrix (α-cyano-4-hydroxycinnamic acid or sinapinic acid) in 33% (v/v) acetonitrile/0.1% (v/v) trifluoroacetic acid. Centrifuge briefly to sediment undissolved matrix. Use the saturated solution to prepare samples. Stored for up to 2 weeks at 4°C, protected from light.

For optimum sensitivity, the α-cyano-4-hydroxycinnamic acid matrix supplied by the manufacturer can be repurified (see UNIT 16.3, Support Protocol).

RCU IASLIC CENTRAL UNIVERSITY LIBRARY

Background Information

Analytical HPLC gel filtration and MALDI-MS are relatively rapid and convenient methods that can be used to detect (and in some cases help identify) many protein modifications and potential self-aggregation seen after expression of recombinant proteins. Gel filtration chromatography is one of the oldest methods used to characterize proteins, and its resolution and speed are substantially improved by modern small-particle high-performance resins. The general aim of analytical HPLC gel filtration is to separate and quantify the components of a protein mixture based on their solution size. In the case of recombinant proteins, the method is used primarily to quantify contaminants, especially self-aggregates (Fig. 7.10.1), and to obtain an approximate Stokes radius of each of the sample components. One of the major advantages of gel filtration over other techniques (e.g., SDS-PAGE) is that it is nondenaturing, enabling the separation, quantification, and approximate size determination of oligomers and aggregates of the protein of interest as they occur in solution. Furthermore, gel filtration can be performed in a variety of solution conditions, so the effects of ionic strength, pH, temperature, or reducing agents on the sample may be tested. Other advantages of the technique are that the sample is recoverable—allowing further analyses (e.g., SDS-PAGE or mass spectrometry) to be performed on the separated components—and that the analysis time is relatively short (typically ~30 to 60 min).

There are some limitations of gel filtration, and additional techniques should be used to fully characterize recombinant proteins. Depending on the sensitivity and detector wavelength used, HPLC analysis may fail to detect some contaminants that might be seen by SDS-PAGE, such as proteins without tyrosine or tryptophan residues, which will not have substantial absorbance at 280 nm. For size determination, HPLC gel filtration is fast, requires very little protein, and gives excellent fractionation, but has inherent drawbacks, such as the potential for retardation of protein elution caused by electrostatic or hydrophobic interactions with the column matrix. For comparison, velocity sedimentation (*UNIT 7.5*) requires no calibration standards and there is no solid phase to interact with the protein, but the fractionation of complex mixtures is not as great. It is important to note that, due to the large variations in protein shape and degree of hydration, a Stokes radius is often not a good indicator of oligomeric state. While HPLC is a rapid first analysis method, the oligomeric state of a protein should be definitively determined using equilibrium sedimentation in an analytical ultracentrifuge (*UNIT 7.5*).

MALDI-MS is an extremely valuable tool for the protein chemist, allowing determination of protein molecular mass within a few daltons, regardless of the size, shape, or hydration of the protein. Other advantages of this technique are that it can be applied to protein mixtures, only ~10 pmol of protein is needed, and the analysis can be completed in a few minutes. The drawbacks of this technique are that some proteins are difficult to ionize and that it is not quantitative, as different proteins can yield highly variable signal intensities. Thus, the utility of MALDI-MS is the accurate mass determination of the protein of interest, which can detect most post-translational and artifactual modifications of that protein. It should also be noted that while obtaining the mass predicted by the sequence of the protein of interest is a good indication that the sequence is correct, confirmation of sequence identity may also require N-terminal sequence analysis of the intact protein and HPLC/MS mapping of tryptic peptides (*UNIT 7.3*).

Critical Parameters

The maximum sample volume that is applied to the column should not exceed 0.5% to 1% of the total column volume for optimal resolution of the sample components. Sample capacity may be increased by using a larger-diameter column. Another way of achieving maximum resolution of components is to place two or more columns in series, effectively increasing the length of the column. Using columns of smaller particle size can increase the resolution of closely eluting components as well as reducing band broadening. Using a lower flow rate than the maximum recommended by the manufacturer may also lead to better resolution of closely eluting components.

Proper care of the columns and HPLC system will ensure the maximum lifetime of the system. After use, the columns and HPLC system should always be stored in a bacteriostat as recommended by the manufacturer. Worn pistons and seals should be replaced to maintain flow rate, and hence retention time reproducibility. Factors that can reduce the lifetime of a column include deposition of aggregated ma-

BAYLOR CENTRAL UNIVERSITY LIBRARY

terial on the column frit, introduction of air into the column, running the columns at flow rates and pressures exceeding the manufacturer's recommendations, and exposing silica-based columns to pHs >7.5.

Troubleshooting

The most common problems encountered in HPLC gel filtration are decreased sample recovery, decreased resolution of sample components, increased back pressure, and changes in retention time. The first step in troubleshooting is tracing the problem to its source: the column, sample, buffer, or instrumentation. Use a process of elimination to find the source by changing or removing one component of the system at a time.

Decreased sample recovery may be due to adsorption of the sample to the column matrix. It has been the authors' observation that some proteins tend to adhere to silica-based matrices. In particular, hydrophobic or membrane proteins may not elute from the column except in the presence of a detergent.

A decrease in resolution (due to peak tailing or broadening) or a change in retention time is often due to the formation of a void at the top of the column bed or a dead volume elsewhere in the system—e.g., a bad tubing connection between the column(s) and the detector, which creates a small mixing chamber. A void at the top of the column can be due to bed compression, introduction of air onto the column, or dissolution of silica at pHs >7.5. Bed compression can occur if the flow rate or back pressure is too high. To prevent particulate matter from clogging the frit or column matrix, buffers should be filtered and samples should be filtered or centrifuged prior to injection. Another method is to install a guard column in front of the fractionating column, which will trap any particles or precipitating proteins that are accidentally introduced into the system. Air bubbles can occur if the buffer has not been degassed properly, or they may be introduced into the system during sample injection if the sample loop is not completely filled with buffer and sample. A void may be filled using some of the same column matrix; however, care should be taken not to disturb the existing column bed.

An increase in back pressure may be due to a clogged frit. The best remedies for this are to reverse flush the column, clean the column according to the manufacturer's recommendations, or replace the end fitting. When cleaning the column, make sure the cleaning buffers are compatible with all other components of the system. The column should be run at a lower flow rate and the detector should be taken out of line. The column frit should also be changed if a visible space develops between the adaptor and the filter.

Resolution of the columns should be checked with a standard protein mix rather than with an experimental sample. An experimental sample may contain either a leading or trailing edge due to other components or impurities, such as aggregated or proteolyzed material. Routine column tests using a well-characterized standard mixture also facilitate comparative monitoring of a column's performance over the lifetime of the column.

Problems with mass spectrometry usually involve failure of the protein sample to ionize (no signal), or signal suppression due to internal standards or buffer components such as high salt or detergent. Ionization of a sample may be improved by experimenting with different matrices, sample concentrations, sample/matrix ratios, and laser power. Signal suppression due to buffer components can be remedied by dialyzing the sample into an MS-compatible buffer such as ammonium bicarbonate.

Anticipated Results

If the recombinant protein is pure and exists in a single oligomeric state with no aggregation or degradation, it is anticipated that the HPLC chromatograph will show a single, symmetrical peak. Additional peaks that elute before the protein of interest may be oligomers or aggregates of the protein, or contaminants. Peaks eluting after the protein of interest may be proteolysis products of the protein or contaminants. To identify the components, collect fractions throughout the separation procedure and analyze by another technique such as SDS-PAGE (*UNIT 10.1*), MALDI-MS (see Support Protocol 2), immunoblotting (*UNIT 10.10*), or N-terminal sequencing (*UNIT 11.10*). MALDI-MS analysis of a pure sample with the correct sequence will show a single peak with a mass that should be within 0.1% of that expected from the amino acid sequence. Final confirmation of identity can be obtained by N-terminal sequence analysis of the intact protein and/or tryptic peptide mapping (*UNIT 7.3*). Additional peaks in the spectrum may sometimes be identified by their mass (Table 7.10.3).

Time Considerations

Equilibration of the gel filtration column typically takes several hours. In some cases, equilibration may have to be performed over-

FSU IAS / CENTRAL UNIVERSITY LIBRARY

night. An analytical HPLC gel filtration run can typically be performed in ~30 min depending upon flow rate and column length.

Capillary Electrophoresis of Peptides and Proteins Using Isoelectric Buffers

Capillary electrophoresis (CE) is a high-resolution separation technique that has become a valuable tool in the analysis of many molecules. *UNIT 10.9* describes the basic concepts, instrumentation, and theory of this technology. Recent developments in the field have resulted in improvements to the procedure, and one such methodology, capillary zone electrophoresis (CZE) in amphoteric, acid buffers, is presented here.

CZE has some marked advantages over standard CE technology. For example, by using isoelectric, amphoteric buffers that have very low conductivity, CZE can accommodate high-voltage gradients (up to 800 V/cm), allowing fast separation. In addition, the acidic buffers—typically with isoelectric point (pI) values in the pH range 2.5 to 3.5—allow the use of naked, fused-silica capillaries (i.e., capillaries in which the inner surface has not been derivatized in order to suppress silanol ionization). This is an important advantage, as it drastically lowers the costs of the separation column (the cost of a fused-silica capillary soars from a few dollars/meter for an untreated material to a few hundred dollars/meter for passivated surfaces). Finally, the acidic pH values of the background electrolyte permits maximization of the net positive charge of peptide/protein analytes via protonation of Glu and Asp residues. This further accelerates the migration process and thus further reduces analysis time.

This unit presents methods for fast protein and peptide analysis in uncoated capillaries by CZE. Because the amphoteric buffers used are key to the success of the experiment, the authors have carefully studied the properties and uses of the buffers for the achievement of optimum results, and these parameters are outlined below (see Strategic Planning). Due to the acidic environment, it cannot be expected that proteins will maintain their native structure and integrity. Thus, these separations are routinely performed in 6 to 7 M urea, which accelerates the process of denaturation and helps keep the proteins in solution. As a consequence, if a protein is oligomeric, the present CZE technique will detect only the component subunits. Basic Protocol 1 details the procedure for analytical peptide separations, while Basic Protocol 2 outlines the separation of protein mixtures. An Alternate Protocol describes the detection of point mutations, a variation on Basic Protocol 2 that has applications in clinical studies. For additional information on the fundamentals of capillary electrophoresis, see *UNIT 10.9*.

STRATEGIC PLANNING

Properties of Amphoteric, Isoelectric Buffers

To perform CZE peptide/protein separation in uncoated capillaries, the buffer must have a pH close to the neutralization point of the silica wall, determined to be pH 2.3. Given an average pK value of silanols of 6.3, essentially all silanols should be protonated at pH 2.3, and thus should be unable to adsorb proteinaceous samples by an ion-exchange mechanism. Four such acidic, amphoteric buffers have been tested for use in this system: cysteic acid (Cys-A; pI 1.85), imino diacetic acid (IDA; pI 2.23), aspartic acid (Asp; pI 2.78), and glutamic acid (Glu; pI 3.22). Their properties are listed in Figure 10.13.1. The following parameters should also be considered when choosing a buffer.

Isoelectric point

The pI is not an absolute value, but a limiting pH value. At vanishing concentrations of the amphotere in solution, the pH will tend to the pI of pure water (pH 7.0); at high enough

Electrolyte	Chemical formulas	pK_1	pK_2	pK_3	pI	$\lvert pI - pK_{prox} \rvert$
Cysteic acid		1.55	2.15	8.7	1.85	0.3
Imino diacetic acid		1.73	2.73	ND	2.23	0.5
Aspartic acid		1.88	3.66	9.9	2.77	0.89
Glutamic acid		2.19	4.25	9.5	3.22	1.03

Figure 10.13.1 Properties of amphoteric, acidic, isoelectric buffers. ND, not determined.

concentrations, the pH will tend to the true pI of the amphotere. For Cys-A and IDA, the given pI value corresponds to a 100 mM solution; for Asp and Glu, it corresponds to a 50 mM solution.

The ($pI - pK_{prox}$) difference

pK_{prox} indicates a protolytic group active in the proximity of the pI value. In the case of Figure 10.13.1, it refers to either pK_1 or pK_2. The absolute value of the difference between pI and pK_{prox} represents a hallmark of the amphotere. Very small values (≤1.0) indicate a very good species, possessing a high buffering capacity at pH = pI. Larger values (≥2) indicate a poor compound, unable to properly buffer at its pI value. Note that it is quite irrelevant which pK value will be displayed by the amino group in the molecule; any pK value above 6.0 will be compatible with the given buffer pIs.

Solubility

Cys-A and IDA display very high solubilities in water, whereas Asp and Glu are soluble only up to 50 mM (at 25°C).

Compatibility with organic solvents

Cys-A and IDA are compatible with a number of organic solvents, such as trifluoroethanol (TFE) and hexafluoropropanol (HFP), which impart unique electrophoretic properties to peptides. In contrast, Asp and Glu are compatible with only 10% TFE.

Conductivity

The lower the pI, the higher the conductivity of the amphotere, due to dissociation of bulk water. Thus, Cys-A and IDA should preferably be used in the presence of organic solvents (such as TFE and HFP) or 7 M urea, which, in addition to modulating the mobility of peptides and proteins, also act as conductivity quenchers.

BCU IAS / CENTRAL UNIVERSITY LIBRARY

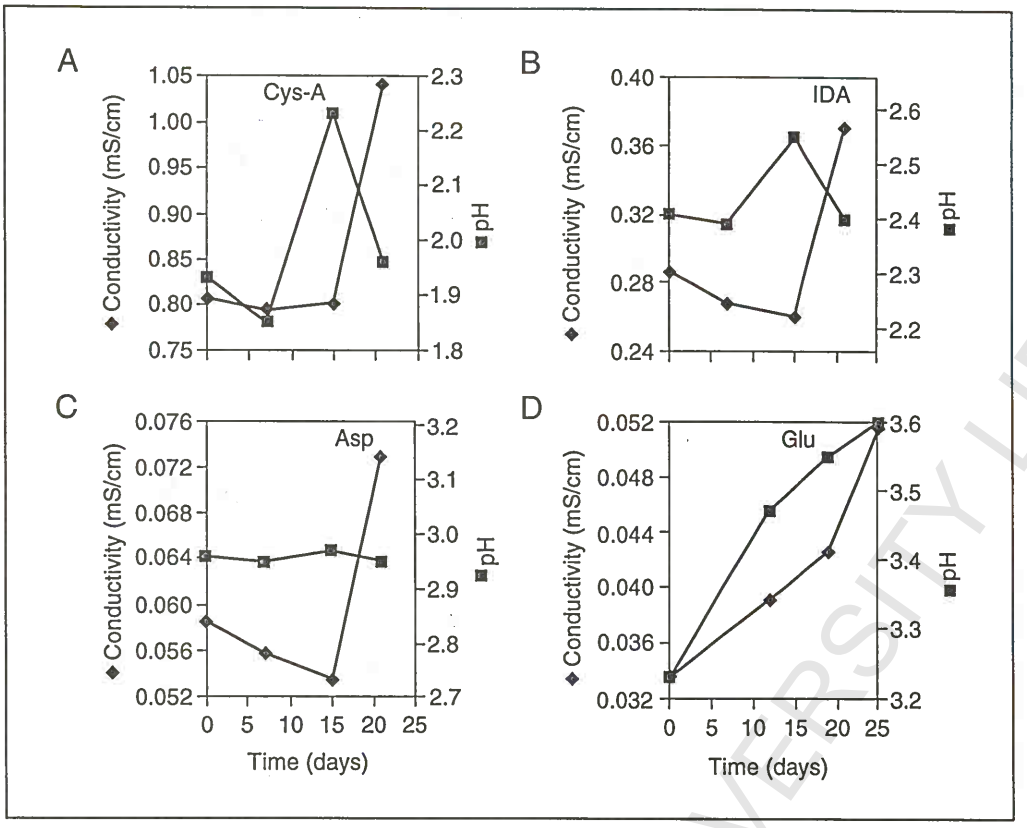

Figure 10.13.2 Conductivity and pH profiles of Cys-A (**A**), IDA (**B**), Asp (**C**), and Glu (**D**) upon aging for three weeks at room temperature. The four amphoteres were dissolved at 50 mM in plain water (unpublished data).

Addition of liquid polymers

Although the acidic pH values adopted should ensure the absence of interaction between peptides or proteins and the silica wall, in reality this risk always exists. Thus, in all buffer formulations reported, small amounts of liquid polymers are added—typically 0.5% (w/v) hydroxyethyl cellulose (HEC; mol. wt. 27,000 Da). HEC (or other liquid polymer) is dissolved at concentrations well below the entanglement threshold and does not exert any sieving of the macromolecular analytes. However, it is very effective in forming a "dynamic coating" on the silica wall, thus preventing binding of polypeptides.

Use of neutral and alkaline amphoteres

Although histidine and lysine could be excellent amphoteric ions for such separations, the authors have chosen not to address them. Histidine has been excellent for oligonucleotide separations (Gelfi et al., 1996), and the use of lysine has been reported for analysis of native proteins (Hjertèn et al., 1995). However, coated capillaries should be used with these amphoteres, considerably adding to the burden and expenses of the technique.

Long-Term Stability of Amphoteric, Isoelectric Buffers

Shelf life

An assessment of the shelf life of isoelectric buffers, dissolved as pure species in plain water as a solvent and stored at room temperature, determined that the final pH of such solutions approaches the pI value of each compound (P.G. Righetti, unpub. observ.). Because quite a number of solutions have strongly acidic pI values, they could potentially degrade at such local pH values. As indicators of potential degradation, pH and conductivity changes as a function of storage time were evaluated. Figure 10.13.2 gives these variations for four compounds, in order of increasing pI values: Cys-A, IDA, Asp, and

BILKENT UNIVERSITY LIBRARY

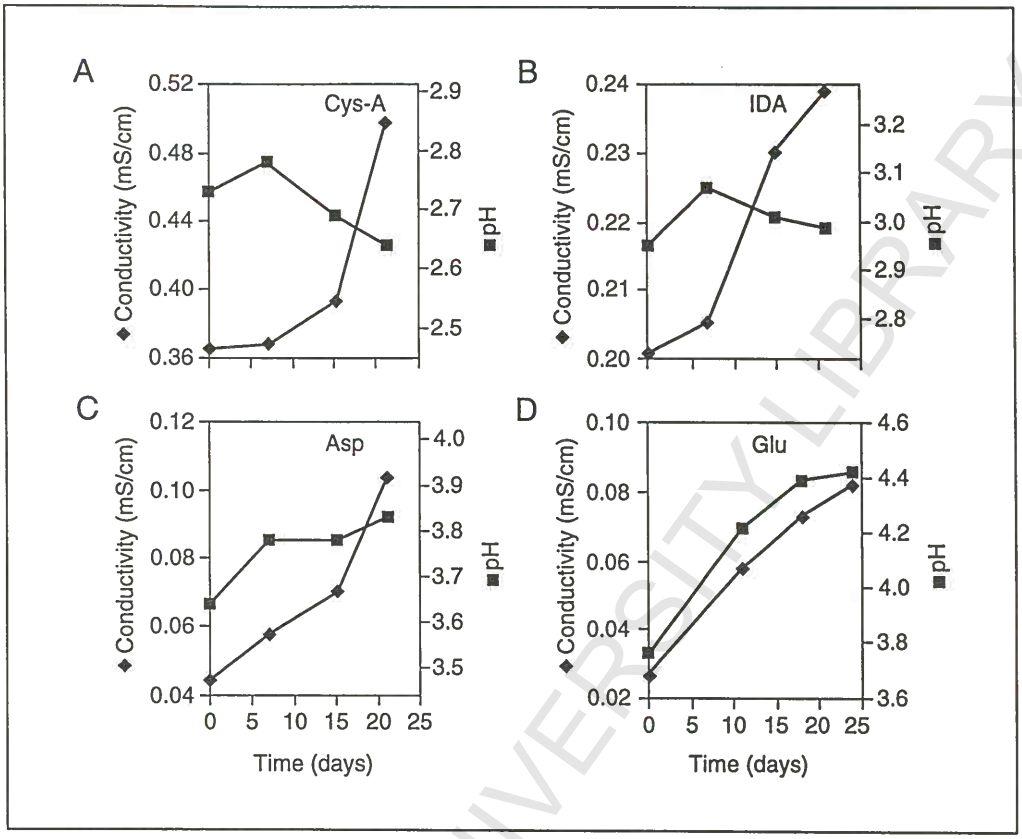

Figure 10.13.3 Conductivity and pH profiles of Cys-A (**A**), IDA (**B**), Asp (**C**), and Glu (**D**) upon aging for three weeks at room temperature. The four amphoteres were dissolved at 50 mM in an aqueous 6 M urea solution (unpublished data).

Glu. Changes were monitored for a period of up to 3 weeks. There seems to be a general trend emerging in all four compounds: the pH and conductivity of all solutions remain stable for a period of ~10 days, after which there appear to be fluctuations in both parameters. In some cases, the pH changes appear to be very minute (e.g., Fig. 10.13.2C, Asp) or to be nonmonotonic (e.g., Fig. 10.13.2A and B), so it would seem that they could be neglected. On the contrary, the conductivity increases steadily for all solutions analyzed, and this increase (in some cases quite marked) appears to be substantial after a period of 2 weeks.

Figure 10.13.3 displays the monitoring of the same parameters for the set of four compounds dissolved in 6 M urea. Here too it is difficult to draw any conclusions from the shape of the pH curves: they either fluctuate or give minimal absolute changes with time, except for Asp and Glu, which show a steady increase in pH for a total of 0.2 and 0.6 pH units, respectively, over a period of 3 weeks. Conductivity changes, on the other hand, are quite marked and appear to increase constantly for all buffers studied. In addition, the onset of such conductivity increments occurs quite early compared to the same solutions in the absence of urea (typically after only a few days).

Making and using new stocks of buffers

Another practical point of interest to users of CZE is how often one should replenish the anolyte and catholyte solutions, so as to avoid electrode polarization as well as marked changes of buffer pH and conductivity due to buffering ion and counter ion depletion. This point, in principle, should not be critical when using isoelectric buffers; their depletion at either electrode should be negligible, because they should not bear a net charge. Figure 10.13.4 explores potential pH and conductivity variations as a function of time of operation of the CZE instrument under a constant electric field of 20,000 V, using

BCU IASE CENTRAL UNIVERSITY LIBRARY

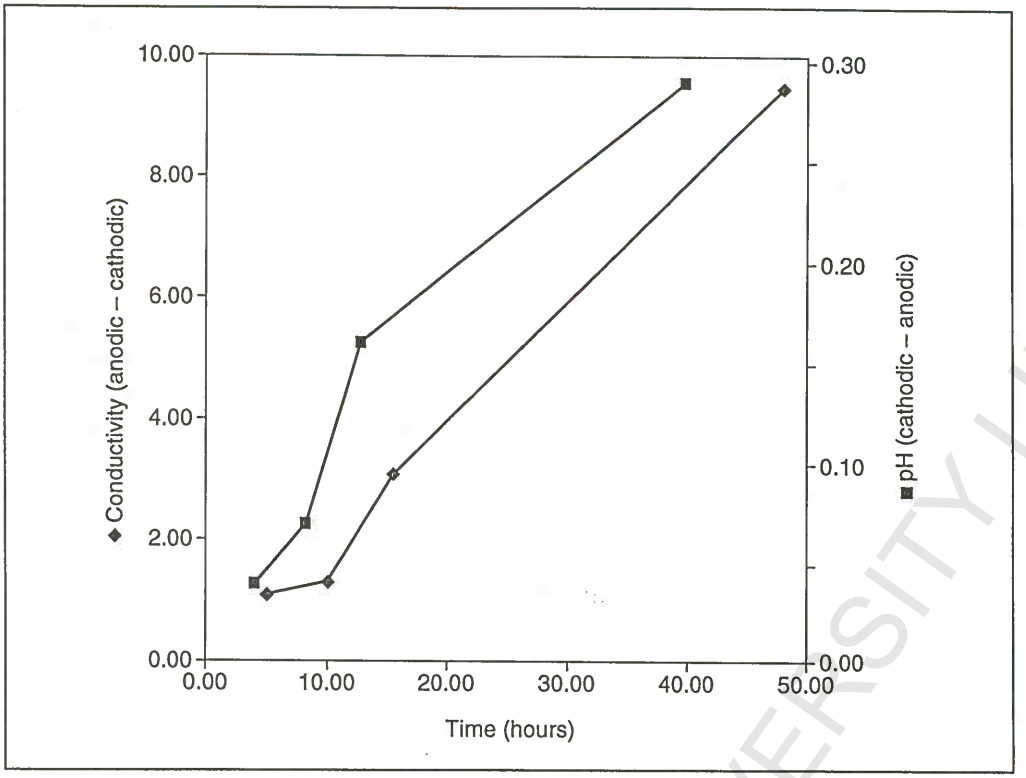

Figure 10.13.4 Conductivity and pH profiles of 40 mM Asp with 6M urea and 0.5% HEC, used for up to 50 hr as anolyte and catholyte. Electrophoretic conditions: 20 kV at room temperature without any change of electrolytes. The data are expressed as the difference in conductivity and pH measured in the two electrodic vessels (unpublished data).

Asp as the sole buffering species in all compartments (anode, cathode, capillary lumen). The data are expressed as the difference in pH and conductivity between the two electrode vessels. Note that in continuous operation the pH increases at the cathode, whereas the conductivity increases at the anode. This means that there must be a net transport of Asp from the cathodic to the anodic vessel. If that is the case, the pH should keep increasing at the cathode and decreasing at the anode. Decrements of pH in the anodic vessel should bring about increments of conductivity. This is to be expected. In fact, at progressively more acidic pH values, a fraction of the amphotere should be nonisoelectric in order to neutralize the excess positive charges brought about by bulk water ionization. For example, in a solution of Asp at pH 3.0, there must be 1 mM proton concentration, which must be neutralized by a 1 mM fraction of Asp being nonisoelectric and negatively charged. This excess, nonisoelectric, molar fraction will constantly migrate towards the anode, creating an imbalance in the concentration of Asp between the two electrodic vessels. This phenomenon can be neglected during the first 10 hr of operation, but after that it becomes quite appreciable.

Practical approaches

Considering the information given above, the following guidelines should apply to CZE in isoelectric, acidic buffers:

1. Buffers, especially if made in the presence of urea, should be prepared fresh every week, stored at 4°C, and then discarded.
2. Anolyte and catholyte solutions should be refreshed after each run when using the most acidic buffer (Cys-A). As the pI increases, the electrodic solutions can be progressively used for a few sequential runs before replenishing (e.g., in case of Asp, buffer can be used for a full day of operation before being discarded).

BOURNEMOUTH UNIVERSITY LIBRARY

3. As a corollary to the above, monitoring the electrodic vessels for pH and conductivity changes will give a sure indication of when to refresh these solutions.

BASIC PROTOCOL 1

ANALYTICAL PEPTIDE SEPARATIONS

CZE is particularly useful for generating peptide maps (fingerprinting) from complex mixtures, such as the products of proteolytic digestion (Bossi and Righetti, 1997; Capelli et al., 1997; Righetti and Nembri, 1997; McLaughlin et al., 1998). In this procedure, the peptide mixture to be analyzed is placed in a sample vial at the cathodic end of the capillary column. The anodic reservoir contains running buffer. The sample is loaded into the capillary either electrokinetically or by pressure or vacuum, and then the sample vial is replaced by running buffer and electrophoresis begins. The following protocol describes the use of a Bio-Rad Bio Focus 3000 instrument using low-pressure sample injection. Other instruments are capable of similar separations when operated according to the manufacturer's instructions.

Materials

Peptide mixture (e.g., β-casein digestion; see recipe)
0.1 M NaOH
Asp buffer: 50 mM aspartic acid (pH = pI = 2.77) containing 0.5% (w/v) hydroxyethyl cellulose (HEC; mol. wt. 27,000 Da, conductivity at 25°C 0.42 mS/cm)
Capillary: 37-cm length (32.4 cm to the detection window); 75-µm i.d., 375-µm o.d. (Polymicro Technologies)
Capillary zone electrophoresis (CZE) instrument (Bio Focus 3000, Bio-Rad, or equivalent)

1. Precondition a new capillary by flushing it with the following solutions, and then store the column in Asp buffer at 25°C.

   1 M NaOH (1 hr)
   H_2O (15 min)
   1 M HCl (2 hr)
   H_2O (15 min)
   0.1 M NaOH at high pressure (30 min)
   H_2O (5 min)
   Asp buffer (30 min).

   When changing to a different separation buffer, equilibrate the capillary for 4 hr with the new buffer by flushing at high pressure for 10 min and monitoring the baseline for 1 hr.

   The preconditioning step is essential if a new capillary is being used. If the capillary has already been properly equilibrated in separation buffer, it is best to avoid any conditioning with solutions of widely different pH, so as not to disturb the silica surface and alter its ionization properties.

   The capillary should be stored no more than 5 days

2. Load 10 to 20 nl peptide mixture using pressure injection for 0.2 to 1 sec at 5 psi according to manufacturer's instructions.

3. Separate the peptide mixture using CZE instrument according to manufacturer's instructions and using the following conditions:

   Electrolyte: Asp buffer used as anolyte, catholyte, and for filling the capillary
   Detector wavelength: 214 nm
   Temperature: 25°C
   Voltage: 400 to 600 V/cm
   Run time: up to 20 min.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

4. Between runs, rinse the column with the same Asp buffer used for separations.

When using the same capillary for a series of separations of the same type of sample, store the column in running buffer at room temperature. The capillary can be stored in this state for no more than 5 days.

Figure 10.13.5 gives an example of the development of these peptide maps at 400 or 600 V/cm. Note that in this last case the entire map is developed in only 11 min. The same separation, when using a standard high conductivity buffer (80 mM phosphate, pH 2.0) takes ~70 min, with severe loss of resolution due to diffusional peak spreading.

SEPARATION OF PROTEINS IN ACIDIC ISOELECTRIC BUFFERS

BASIC PROTOCOL 2

Knowledge of the pIs of the components of the mixture would greatly help in selecting an appropriate run buffer. One capable of maximizing differences in the charge-to-mass ratio and ensuring that the proteins will all migrate towards the detector window. If the pI of a protein is unknown, separations can be achieved by using either a very alkaline or a very acidic buffer. However a coated column must be utilized with very alkaline buffers, so as to suppress any interaction of the analyte with the capillary wall. Therefore, very acidic buffers are preferred, as they should effectively quench adsorption of proteins onto the silanols. There is a catch to this strategy, however—in such an acidic environment proteins will most likely unfold and denature, due to disruption of the hydrogen bonds. Such denaturation could also induce protein aggregation and precipitation. The addition of 6 to 7 M urea in the background electrolyte ensures full denaturation while maintaining solubility of the analyte. Since the addition of 7 M urea will increase the apparent pH of the background electrolyte by ~1 pH unit, it is suggested that low pI buffers, such as IDA (pI 2.33) or Asp (pI 2.77), be used rather than Glu (pI 3.22). Please note that for oligomeric proteins, it is the subunits that will be separated (unless they are held together by disulfide bridges). The following protocol is based on a procedure routinely used for separation of wheat gliadins (Capelli et al., 1998).

Materials

Protein sample (e.g., gliadin extraction; see recipe)
0.1 M NaOH
70% (v/v) ethanol
Asp/urea buffers: 40 mM aspartic acid (pH = pI = 2.77), containing 0.5% (w/v) hydroxyethyl cellulose (HEC; mol. wt. 27,000 Da) and 7 M *and* 5 M urea (apparent pH 3.9; conductivity at 25°C: 0.7 mS/cm; both values refer to 7 M urea solutions)
Capillary: 30-cm length (25.4 cm to the detection window), 50-µm i.d., 375-µm o.d. (Polymicro Technologies)
Capillary zone electrophoresis (CZE) instrument (Bio Focus 3000, Bio-Rad, or equivalent)

1. Precondition a new capillary by flushing it with the following solutions. After equilibration, store in water at 25°C.

1 M NaOH (1 hr)
H_2O (15 min)
1 M HCl (2 hr)
H_2O (15 min)
0.1 M NaOH at high pressure (30 min)
H_2O (5 min)
Asp buffer/7 M urea buffer (30 min)

When changing to a different separation buffer, equilibrate the capillary for 4 hr with the new buffer by flushing at high pressure for 10 min and monitoring the baseline for 1 hr.

BOULDER CENTRAL UNIVERSITY LIBRARY

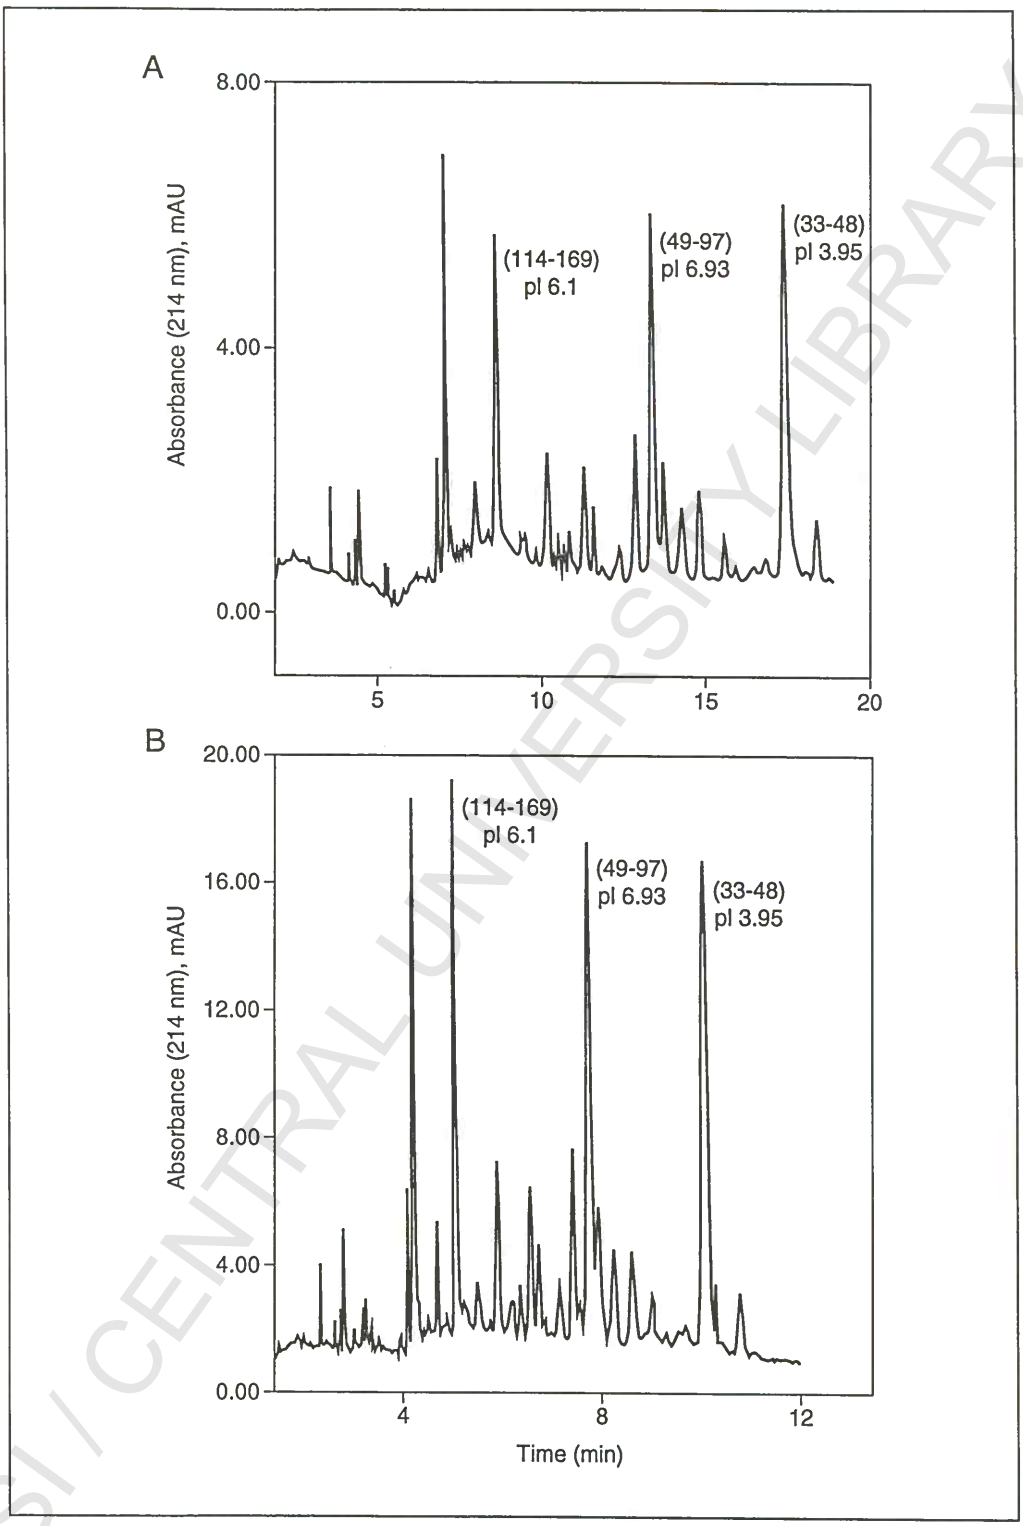

Figure 10.13.5 CZE of tryptic digests of β-casein in a 37-cm × 100-μm-i.d. capillary bathed in 50 mM isoelectric Asp (pH approximating the pI value of 2.77) with 0.5% HEC. (**A**) 400 V/cm (current: 33 μA); (**B**) 600 V/cm (current: 58 μA). The three major labeled peaks are (from left to right) the pI 6.1 fragment (β-CN 114-169); the pI 6.9 fragment (β-CN 49-97) and the pI 3.95 fragment (β-CN 33-48). CN, casein. Reproduced from Righetti and Nembri (1997), with permission from Elsevier.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

The preconditioning step is essential if a new capillary is being used. If the capillary has already been properly equilibrated in separation buffer, it is best to avoid any conditioning with solutions of widely different pH, so as not to disturb the silica surface and alter its ionization properties.

2. Dilute the protein sample 1:5 (v/v) with 70% ethanol to give a final concentration of 2 mg/ml.
3. Fill the uncoated capillary with Asp/urea buffer containing 7 M urea. Fill the anode and cathode reservoirs with Asp/urea buffer containing 5 M urea.
4. Inject the sample hydrodynamically (e.g., 3 sec at 1 psi) according to manufacturer's instructions.

   For a 2 mg/ml sample, 0.2 sec at 5 psi is sufficient.

5. Separate using the following conditions:

   Electrolyte: Asp/urea buffer containing 5 M urea used as anolyte and catholyte, and containing 7 M urea for filling the capillary
   Detector wavelength: 214 nm
   Temperature: 25°C
   Run voltage: 800 to 1000 V/cm
   Run time: 15 min.

   Figure 10.13.6 gives an example of a CZE run of four different cultivars of durum wheat, and Figure 10.13.7 gives an analogous separation for four cultivars of bread wheat. Note that these separations are typically over in 10 to 12 min. In contrast, the same separations performed in standard 100 mM phosphate buffer, pH 2.5, last for >30 min.

6. Between runs, rinse column with the same Asp/urea buffer used for separations.

SEPARATION OF POINT MUTATIONS IN POLYPEPTIDE CHAINS

ALTERNATE PROTOCOL

Detection of point mutations is important in identifying several congenital defects of major clinical interest. For example, in the case of hemoglobinopathies, >600 defective variants of hemoglobin (Hb) have been reported. Among those, approximately one third involve a neutral-to-charged amino acid substitution, easily detectable by routine electrophoretic techniques, since they bring about a variation of the net charge of the expressed polypeptide. However, approximately two thirds represent the so-called electrophoretically silent mutations, in that they involve a neutral-to-neutral amino acid substitution. In this last case, not only is there no appreciable change in net charge, but the variation of polypeptide mass is also so minute as to escape detection by SDS-PAGE (*UNIT 10.1*). It has recently been demonstrated that addition of a neutral surfactant can in fact induce separation of the wild-type and mutant chains, probably by hydrophobic interaction of the more hydrophobic mutant with the detergent micelle, via a mechanism similar to micellar electrokinetic chromatography (Terabe et al., 1985). This is a protocol the authors routinely utilize for separation of point mutations in human globin chains (Righetti et al., 1998a; see also Regnier and Lin, 1998; Righetti et al., 1998b).

Additional Materials (also see Basic Protocol 2)

Protein sample (e.g., globin chain preparation; see recipe)
IDA buffer: 50 mM imino diacetic acid (pH = pI = 2.23), containing 0.5% (w/v) hydroxyethyl cellulose (HEC; mol. wt. 27,000 Da) and 7 M *and* 5 M urea (apparent pH 3.2; conductivity at 25°C: 176 µS/cm)
Uncoated capillary, 33-cm length (26 cm to the detection window), 50-µm i.d., 375-µm o.d. (Polymicro Technologies)
Capillary zone electrophoresis (CZE) instrument (Bio Focus 3000, Bio-Rad, or equivalent)

B. C. U. „M. EMINESCU" IAŞI
CHIMIE

BCU IAŞI CHIMIE UNIVERSITY LIBRARY

1. Condition the capillary (see Basic Protocol 2, step 1).
2. Fill the uncoated capillary with IDA buffer solution containing 7 M urea buffer. Fill the anode and cathode reservoirs with IDA buffer solution containing 5 M urea.

   If studying neutral point mutations, add 2% reduced Triton X-100 to the buffer.
3. Inject the sample hydrodynamically (e.g., 3 sec at 1 psi or 0.2 sec at 5 psi) according to manufacturer's instructions.
4. Separate using the following conditions:

   Electrolyte: IDA buffer containing 5 M urea used as anolyte and catholyte, and containing 7 M urea for filling the capillary
   Detector wavelength: 214 nm
   Temperature: 15°C
   Run voltage: 600 V/cm
   Run time: 10 min.

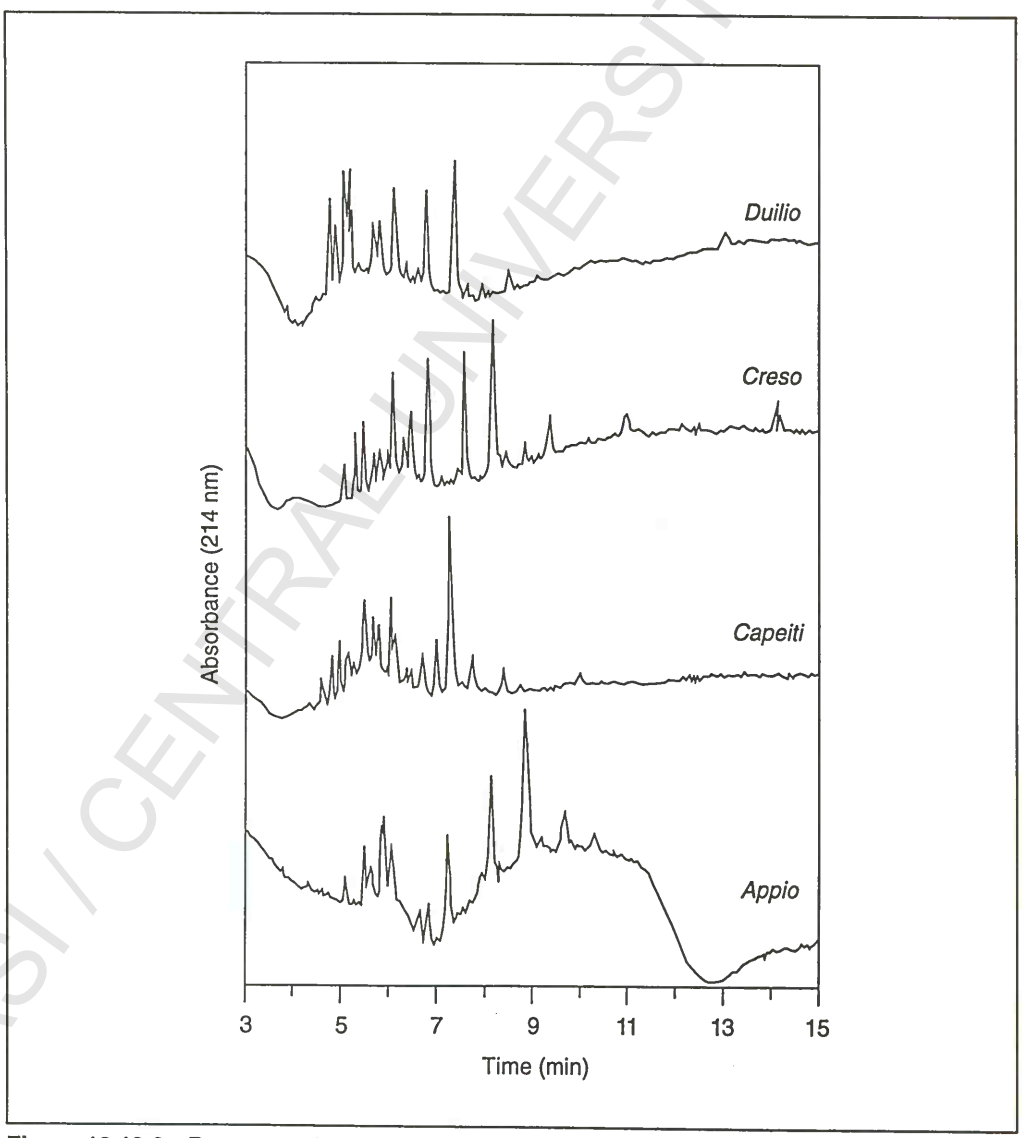

Figure 10.13.6 Representative CZE run of gliadins, obtained by sequential extraction of flour from four different cultivars of durum wheat. Run performed in 40 mM Asp with 7 M urea and 0.5% HEC (apparent pH 3.9). Conditions: 50-µm-i.d. × 30-cm-long capillary, run at 1000 V/cm, room temperature. From Capelli et al. (1998), with permission from Wiley-VCH.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Figure 10.13.8 gives an example of a separation of a β-chain mutant in both control (in the absence of surfactant) and background electrolytes containing 2% (v/v) reduced Triton X-100. Notice, in the lower panel, the splitting of the two β-chains, which coelute in the absence of surfactant. Note that these separations are typically over in 6 to 7 min. The same separations performed in standard 100 mM phosphate buffer, pH 2.2, take ~20 min.

REAGENTS AND SOLUTIONS

Use Milli-Q-purified water or equivalent in all recipes and protocol steps. For common stock solutions, see ***APPENDIX 2E****; for suppliers, see* ***SUPPLIERS APPENDIX****.*

β-casein digestion

Dissolve 10 mg/ml β-casein in 50 mM 3-(cyclohexylamino)-1-propanesulphonic acid (CAPS) buffer, pH 8.2. Add trypsin at a trypsin/β-casein ratio of 2% (w/w). Allow to hydrolyze for 4 hr at 50°C. Stop the reaction by adding 4 M acetic acid to pH 4.0. Store the tryptic peptide digest up to 6 months at –20°C.

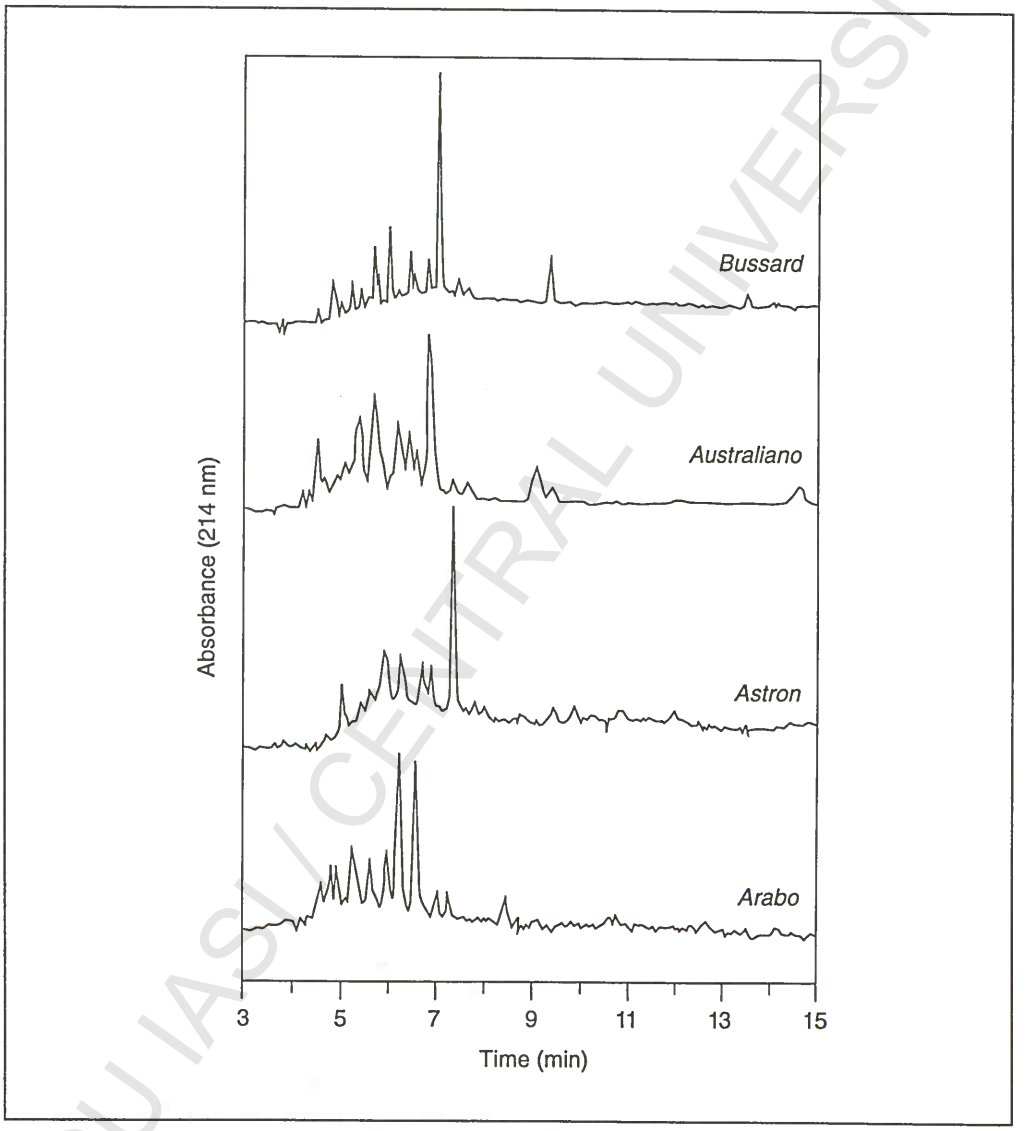

Figure 10.13.7 Representative CZE run of gliadins, obtained by sequential extraction of flour from four different cultivars of bread wheat. Run performed in 40 mM Asp with 7 M urea and 0.5% HEC (apparent pH 3.9). Conditions: 50-μm-i.d. × 30-cm-long capillary, run at 1000 V/cm, room temperature. From Capelli et al. (1998), with permission from Wiley-VCH.

DOU IASI / CENTRAL UNIVERSITY LIBRARY

Gliadin extraction

In the direct extraction, extract 30 mg bread or durum wheat flour while vortexing for 30 min at room temperature with 0.5 ml cold 70% (v/v) aqueous ethanol. Centrifuge for 15 min at 11,000 × *g*, 20°C. Use the supernatant, containing mostly gliadins (10 mg/ml), as is for CZE analysis. Store up to 6 months at –20°C.

Globin chain preparation

Wash red blood cells in physiological saline (0.9% NaCl), lyse in distilled water, and pellet the resulting "ghosts" by centrifuging 5 min at 5000 × *g*, 4°C. Add 20 µl concentrated hemoglobin (Hb) solution dropwise to 1.5 ml acetone containing 2% (v/v) HCl (at room temperature) in a microcentrifuge tube. Centrifuge again as before, discard the supernatant and resuspend the pellet in water. Repeat the centrifugation again, discarding the supernatant, in order to obtain a white globin powder. Dry the

pellet in a Speedvac evaporator. Prior to analysis, dissolve the globin powder at a concentration of 2 mg/ml in background electrolyte containing 2% (v/v) 2-mercaptoethanol and only 5 (instead of 50) mM IDA. Store up to 6 months at –20°C.

COMMENTARY

Background Information

CZE of proteins and peptides has usually been performed either at very acidic (pH 2 to 2.5) or rather alkaline (pH 9 to 10) pH values. Under alkaline conditions, a coated capillary has to be used, in order to quench the electroendoosmotic flow (EOF) and to minimize residual adsorption to fully ionized silanols. Under acidic conditions, a naked capillary can be used, but the very high conductivity of such acidic buffers (notably phosphate), allows only low-voltage gradients (e.g., maximum 100 V/cm) with concomitant very long analysis times.

The first report on the use of amphoteric buffers, used as the sole background electrolyte at pH = pI, came from Hjertèn's group in 1995 (Hjertèn et al., 1995). This group could separate albumin and transferrin in only 40 sec using 15-cm-long capillaries at 2000 V/cm in low-conductivity polymeric buffers (pH 8.6). In 5 mM Lys (pH = pI = 9.7), a mixture of different protein markers (soybean trypsin inhibitor, ovalbumin, conalbumin, and myoglobin) could also be separated in 240 to 40 sec at voltage gradients ranging from 330 to 2000 V/cm. However, while Hjertèn's procedure solved the problem of fast analysis times, it had to adopt capillaries with an inner coating of polymeric material (usually polyacrylamide) covalently anchored to the silanols.

The first article published dealing with the use of amphoteric, isoelectric buffers was that of Mandecki and Hayden (1988), on the use of His as the sole buffering ion in slab gel electrophoresis of DNA. Although this methodology appeared in 1988, it went largely unnoticed until it was rediscovered by Hjertèn's group. The authors have also adopted isoelectric His in CZE for the fast separation of antisense oligonucleotides in liquid-sieving polymers (Gelfi et al., 1996). The main difference between previous data and the present technique resides in the use of acidic, isoelectric buffers, with all the benefits inherent to this methodology, such as fast analysis times, high resolution, and the ability to use untreated fused-silica capillaries.

Critical Parameters

For separation of peptides (see Basic Protocol 1), it is generally not necessary to add urea, as these fragments are well soluble in plain water solvent because of their relatively small size and good hydrophilicity. One exception would be peptides obtained from hydrophobic (e.g., membrane) proteins—these samples run the severe risk of aggregating and/or precipitating. In this case, addition of urea, possibly also combined with surfactants, is recommended. If detergents are used, neutral or zwitterionic species (such as reduced Triton X-100 or CHAPS) work best. Do not use Nonidet P-40 or other detergents that contain aromatic rings, as their absorbance at 200 nm will lower the sensitivity of detection.

In mixed hydro-organic solvents of the water/urea type, it should be remembered that, due to the heat developed in a capillary unit and to the strong air streams in equipment that uses forced-ventilation cooling, there is a strong risk of solvent evaporation in the two electrode vessels. Urea will concentrate and crystallize, blocking the inlet of the capillary. Thus, as a safety precaution, only 5 M urea should be added to the electrode vessels when using buffers containing urea. For the running buffer in the capillary, the urea concentration can be increased to 7 M urea, but not higher than that. With high levels of urea, be sure that the extremities of the capillary are always kept inserted in a vessel containing liquid. When left in the air, the solvent will quickly evaporate from the capillary tips and urea will crystallize.

For protein separations (see Basic Protocol 2 and see Alternate Protocol), there is often the risk that small amounts of protein will be adsorbed onto the silica wall. After repeated injections, there might be a significant alteration of the silica surface, leading to irreproducible results and even to spurious peaks. A simple solution is to dispose of the capillary and start with a new one. However, if the same capillary has to be reused, there are several procedures for regenerating the silica wall. In one (drastic) treatment, the capillary can be rinsed with 0.1 N (or even 1 N) NaOH. Alkaline treatments are very effective in removing and solubilizing proteinaceous material and most adsorbed impurities. Unfortunately, such a drastic procedure will ionize most of the surface silanols and deeply alter the surface properties of the silica

BOURNEMOUTH UNIVERSITY LIBRARY

wall. In addition, because alkaline treatments are abrasive, part of the silica surface can be dissolved. As a result, it might be very difficult to recondition the capillary wall to the original properties and obtain reproducible results in electroendoosmotic flow and transit times.

A better way to remove adsorbed material is by rinsing the capillary with running buffer containing micellar SDS (e.g., 30 mM SDS). However, if the running buffer has too low a pI, the SDS micelles might not be effective—in this case, dissolve the SDS in Good's buffers (e.g., MES or MOPS, titrated at pH 6.8). The running buffer/SDS solution is placed at the cathode and the SDS micelle is transported electrophoretically into the capillary. The migrating SDS micelles act by sweeping any silica-bound material, which will be adsorbed into the micelle and migrate with the SDS front. If this operation is conducted under UV monitoring, a peak of desorbed material will be seen at the passage of the SDS micelles. This electrophoretic desorption can be continued for 30 min under constant electric field. This process is the electrophoretic analog of frontal chromatography. After this step, the SDS micelles can be removed by rinsing with water and then the capillary can be reconditioned by purging with the chosen isoelectric running buffers (10 column volumes; see Basic Protocol 1, step 1), in the presence of the proper additives, if any.

It appears that the two best buffers, in general, are IDA and Asp. Cys-A is strongly acidic and does not offer particular advantages over such a strongly conducting buffer as phosphate, titrated at pH 2.0 to 2.5. Cys-A is best used in presence of conductivity quenchers, such as urea and/or organic solvents (TFE and HFP) that are compatible with this buffer and with bulk water at any concentration (although, typically, no advantage is obtained at concentrations greater than 40%, v/v). Cys-A seems to be particularly attractive when analyzing small (di-, tri-, and tetra-) peptides that bear the terminal carboxy and amino groups as their only charged groups. In fact, such peptides are isoelectric over a broad pH range (typically at least 4 to 8), so that either strongly acidic or strongly basic solutions are needed in order to provide sufficient charge for a fast separation.

Glu is also an interesting buffer, because its higher pI (3.22, especially when in presence of urea, apparent pH 4.3) allows modulation of the net charge of large peptides, due to partial deprotonation of Asp and Glu residues. Thus, in general, the titration curves of polypeptides tend to fan out at and above pH 4, allowing mobility modulation and increased selectivity. The risk with Glu, however, is that at this higher pH (especially in the presence of 7 M urea) polypeptides might bind to ionized silanols, resulting in loss of resolution. Thus, when adopting Glu as a background electrolyte, one should perform preliminary runs in order to identify potential interaction of the silica wall with the components of the protein mix under analysis.

Troubleshooting

Potential mechanical and/or electrical problems that might be encountered during instrument use are usually addressed in the manufacturer's manual. Therefore, this discussion will focus on problems encountered with the sample and background electrolyte. The most common problems encountered in CZE are discussed below.

Loss of current during a run

A typical problem is the sudden or gradual loss of electric contact during a run. Sudden loss of electric contact could be due to a breaking of the capillary or the trapping of a large air bubble spanning the entire lumen of the capillary. Gradual loss of current could be caused by small air bubbles that develop during the run (e.g., due to excess power forcing the solution to outgas), which adhere to the silica wall but are too minute to completely obstruct the lumen. During the run, more air bubbles could develop and further reduce the lumen available to the passage of electric current. On a long run, such tiny air bubbles could coalesce and suddenly break the current (remember that air bubbles can be negatively charged due to adsorption of ions in their diffuse double layer, and thus can migrate in the electric field). Bubbles can be avoided by thoroughly degassing all solutions used in the instrument (including the reservoirs). The authors often adopt a double degassing procedure: under vacuum and also by sonication. It is also a good procedure to check the total applied electric power and see that it does not exceed the power recommended by the manufacturer.

One should also make sure that the sample vial contains enough sample to cover the extremity of the capillary at the injection site, so as to prevent injection of air into the column. Remember that, although the sample volume injected in the capillary is minute (typically 5 to 20 nl), for proper immersion of the capillary end in the analyte solution the vial should contain 10 µl. In addition, the sample vials can

BCU IASI - UNIVERSITY LIBRARY

dry out during a long run, especially when performing sequential runs and placing a large number of samples in the carousel. One would then notice that the later samples give exaggeratedly huge peaks due to excessive liquid evaporation. In order to avoid that, when programming a sequence of runs (e.g., for overnight analyses), the authors have adopted a neat safety procedure, consisting of overlaying the analyte solution with a layer of light paraffin oil. This oil will float on top of the liquid layer of analyte, effectively sealing it from the air and completely preventing evaporation.

Arcing

CZE instruments can arc during a run. This is often caused by salt deposits or moisture on the high-voltage electrode stations. In instruments using a free capillary, not encapsulated in a cartridge, moisture can be deposited all along the capillary's outer surface, causing creeping current on its surface. This can be particularly true in a hot and humid summer environment in the absence of proper air conditioning and dehumidification. A proper cure would be to purge the capillary chamber with dry inert gas and to place Drierite bags in the capillary holding compartment.

Column plugging

The column can plug because of salt deposition as the liquid inside dries out. This is particularly true when using urea-laden buffers. As a safety precaution, if no further use of the capillary is expected at the end of a working day, the column should be emptied and stored overnight in plain water or in urea-free buffer. In general, washing the column with water dissolves the plug if a standard buffer is used; however, in the case of urea-containing buffers, it might be necessary to discard the capillary if extensive deposition of urea has occurred in a substantial portion of its length. Proteins too can precipitate during a run and plug the column. Using lower protein concentrations usually prevents this type of plugging.

Sudden loss of sample resolution

When using very acidic isoelectric buffers (e.g., Cys-A), poor resolution can be caused by ion depletion at one electrode due to electrophoretic migration of the nonisoelectric molar fraction. When this occurs, most of the voltage gradient falls on the electrode vessel depleted of ions, with consequently poor or no migration of the analyte components. Check the electrode pH and conductivity, and refresh the buffer.

Sample tailing

Sample tailing could be due to adsorption of sample ions to ionized silanols. It might occur in two particular cases: when using proteins (peptides are generally too small to elicit substantial binding to the silica wall) and when using progressively higher pI amphoteres, such as Glu. Adsorption of polypeptides to the capillary can be demonstrated by frontal analysis, i.e., by making a blank run in which SDS micelles are added to the cathodic vessel. On their migration to the anode, the SDS micelles will sweep away bound proteins and a sharp sample peak will be detected. The remedy is to adopt lower pI amphoteric buffers and/or increase the amount of sieving liquid polymer (HEC, which should be used below 1%, as it will give too high a viscosity).

Unreproducible transit times

A possible cause of unreproducible transit times could be too short an equilibration period of the capillary in a given buffer. Let the capillary equilibrate overnight, instead of only 4 hr, with frequent periods of pumping the buffer through the column. This will also favor deposition of the HEC polymer onto the inner capillary surface, a process called dynamic coating. Another cause could be a drastic washing step with alkaline solutions (e.g., 0.1 N NaOH). This will ionize a large number of silanols and deeply alter the charge state of the surface. It might then take extensive washings in the original acidic buffer solution in order to reestablish the proper starting surface conditions.

Often, the biggest offender is accumulation of adsorbed material from the sample plug. This material might not necessarily be the protein or peptide of interest, but some impurities in the sample matrix (e.g., lipids). One remedy to it is to try to pre-purify the sample solution, e.g., by a lipid-extraction step. The other remedy is to wash the capillary with a front of SDS micelles, which will quite efficiently desorb bound material by forming mixed micelles.

Anticipated Results

Results of separations obtainable with the experimental conditions outlined here are discussed with each of the protocols (also see Figs. 10.13.5-10.13.8).

Time Considerations

As a virtue of the high voltage gradients that can be applied in isoelectric buffers, the total analysis time is much reduced compared to analogous techniques in conventional, non-

BOSTON CENTRAL LIBRARY

isoelectric buffers. For example, in Asp buffer at the standard voltage of 600 V/cm in a 37-cm-long capillary, analysis is usually over in 10 to 12 min. The total analysis time, including sample loading, running, and capillary regeneration prior to the following run, is typically on the order of 15 min.

CHAPTER 19
Identification of Protein Interactions

INTRODUCTION

Protein interactions are intrinsic and vital to many cellular processes. In recent years many new techniques have been developed for the study of this important topic; the review by Phizicky and Fields (1995) provides an excellent general overview of this subject. This chapter describes biochemical, physical, and genetic methods that are used to detect specific protein interactions. A companion chapter in preparation will present a series of complementary methods that are used to provide quantitative information about protein interactions, such as the strength and kinetics of binding.

This chapter begins with brief overview of the analysis of protein interactions in which some of the basic kinetic and thermodynamic concepts are described (*UNIT 19.1*). This is followed by a presentation of one of the most widely used approaches for detecting protein interactions, the yeast two-hybrid/interaction trap system (*UNIT 19.2*). In this genetic method transcriptional activity is used as a measure of protein interaction.

The technique of interaction cloning or expression cloning based on phage display can be used to identify and clone genes that interact with known proteins of interest. *Escherichia coli* filamentous phages can express fusion proteins bearing foreign peptides on their surface. These peptides are accessible to bind with antibodies or other proteins to which they have some affinity. *UNIT 19.3* details phage expression cloning to identify phage fusion proteins that interact with known targets or bait proteins. One important characteristic of this approach is that the phage fusion protein is directly associated with its gene due to its packaging in a single phage, making it possible to immediately sequence the gene and thereby generate one or more consensus sequences of the bound peptides.

Future plans for this chapter includes a unit on surface plasmon resonance (SPR), another useful method for discovery and detection of protein interactions that is gaining in popularity.

Theoretical Aspects of the Quantitative Characterization of Ligand Binding

Living organisms grow, differentiate, reproduce, and respond to their environment via specific and integrated interactions between biomolecules. The investigation of molecular interactions therefore constitutes a major area of biochemical study, occupying a ubiquitous and central position between molecular physiology on the one hand and structural chemistry on the other. While specificity resides in the details of structural recognition, the dynamic interplay between biomolecules is precisely orchestrated by the thermodynamics of the biomolecular equilibria involved. A consequence is that biochemists of all persuasions are drawn into the quantitative characterization of biomolecular interactions.

Fortunately, a common set of physicochemical principles applies to all such phenomena, irrespective of whether the interaction of interest involves an enzyme and its substrate or inhibitor, a hormone or growth factor and its receptor, an antibody and its antigen, or, indeed, the binding of effector molecules that modulate these interactions. The binding affinity, binding specificity, number of binding sites per molecule, as well as the enthalpic and entropic contributions to the binding energy are common parameters that assist an understanding of the biochemical outcome. This unit aims to provide an overview of the design and interpretation of binding experiments. More extensive treatments are provided by two recent monographs (Winzor and Sawyer, 1995; Klotz, 1997).

RECTANGULAR HYPERBOLIC BINDING RESPONSES

In studies of reversible interactions between two species, the smaller solute is termed the ligand (S) and is usually considered to possess a single site for interaction with the larger species. The latter, designated here as A, is termed either the acceptor or the receptor (if particulate), which may possess several sites for interaction with ligand. For a system entailing the binding of a ligand to p sites on an acceptor, the concentrations of p complexes ($AS, AS_2, .., AS_p$) as well as those of free acceptor and free ligand are required, in principle, for complete description of the composition of an acceptor-ligand mixture. However, under favorable circumstances the problem simplifies to quantitative characterization by determining the free concentration of ligand (C_S) in a mixture with defined total concentrations of acceptor and ligand ($\overline{C}_A$ and $\overline{C}_S$, respectively). This simplification arises when the concentration of bound ligand ($\overline{C}_S - C_S$) exhibits a rectangular hyperbolic dependence upon free ligand concentration (C_S) for mixtures with a fixed total acceptor concentration ($\overline{C}_A$). Such a situation is encountered, for example, with enzymes exhibiting Michaelis-Menten behavior, where the observed dependence of initial velocity upon substrate concentration is the manifestation of a rectangular hyperbolic binding response.

Although binding theory is usually derived for the general case in which a ligand binds to p sites on an acceptor, this discussion presents an alternative derivation for the simpler case where ligand binding is restricted to two acceptor sites. For this system, the various equilibria are described in terms of molar association constants (K_i) by:

BCU INSTITUTIONAL UNIVERSITY LIBRARY

$$-\mathrm{A}-+\mathrm{S} \overset{K_1}{\rightleftharpoons} -\mathrm{A}-\mathrm{S} \quad C_{\mathrm{AS}} = K_1 C_{\mathrm{A}} C_{\mathrm{S}}$$

Equation A.5A.1

$$-\mathrm{A}-+\mathrm{S} \overset{K_2}{\rightleftharpoons} \mathrm{S}-\mathrm{A}- \quad C_{\mathrm{SA}} = K_2 C_{\mathrm{A}} C_{\mathrm{S}}$$

Equation A.5A.2

$$-\mathrm{A}-\mathrm{S}+\mathrm{S} \overset{K_3}{\rightleftharpoons} \mathrm{S}-A-\mathrm{S} \quad C_{\mathrm{SAS}} = K_3 C_{\mathrm{AS}} C_{\mathrm{S}} = K_1 K_3 C_{\mathrm{A}} C_{\mathrm{S}}^2$$

Equation A.5A.3

$$\mathrm{S}-\mathrm{A}-+\mathrm{S} \overset{K_4}{\rightleftharpoons} \mathrm{S}-A-\mathrm{S} \quad C_{\mathrm{SAS}} = K_4 C_{\mathrm{SA}} C_{\mathrm{S}} = K_2 K_4 C_{\mathrm{A}} C_{\mathrm{S}}^2$$

Equation A.5A.4

Completely general characterization thus requires the determination of four equilibrium constants, the only interrelationship between which is identity of the products K_1K_3 and K_2K_4 to maintain independence of the concentration of saturated acceptor-ligand complex (C_{SAS}) upon the pathway of its formation—a thermodynamic necessity because the concentration of saturated complex is either $K_1K_3C_{\mathrm{A}}C_{\mathrm{S}}^2$ or $K_2K_4C_{\mathrm{A}}C_{\mathrm{S}}^2$. The total concentrations of acceptor and ligand may therefore be written in the form:

$$\overline{C}_{\mathrm{A}} = C_{\mathrm{A}}\left[1+(K_1+K_2)C_{\mathrm{S}} + K_1K_3C_{\mathrm{S}}^2\right]$$

Equation A.5A.5

$$\overline{C}_{\mathrm{S}} = C_{\mathrm{S}} + C_{\mathrm{A}}\left[(K_1+K_2)C_{\mathrm{S}} + 2K_1K_3C_{\mathrm{S}}^2\right]$$

Equation A.5A.6

In an experimental context the binding response is usually expressed in terms of a binding function, termed r (Klotz, 1946) or ν (Scatchard, 1949) and defined as the molar ratio of the amount of bound ligand to the total amount of acceptor. On the grounds that these two amounts are contained in the same volume, the binding function for the above system is given by Equation A.5A.7, which is the binding equation in Adair (1925) format.

$$r = \left(\overline{C}_{\mathrm{S}} - C_{\mathrm{S}}\right) / \overline{C}_{\mathrm{A}} = \frac{(K_1+K_2)C_{\mathrm{S}} + 2K_1K_3C_{\mathrm{S}}^2}{1+(K_1+K_2)C_{\mathrm{S}} + K_1K_3C_{\mathrm{S}}^2}$$

Equation A.5A.7

Simplification of Equation A.5A.7 to a rectangular hyperbolic dependence of the binding function upon free ligand concentration entails the incorporation of two separate assumptions: (1) binding sites on the acceptor are equivalent ($K_1 = K_2$), and (2) binding sites on the acceptor are independent ($K_1 = K_4$, $K_2 = K_3$). The former implies identity of the binding characteristics for the interaction of ligand with either site on (for example) a dimeric enzyme comprising two identical subunits, whereas the latter assumption implies that the same binding constant applies to ligand interaction with a given site, irrespective of the occupancy state of the other. These two assumptions allow the description of binding in

UCU IASI / CENTRAL UNIVERSITY LIBRARY

terms of a rectangular hyperbolic response governed by a single intrinsic (site-binding) constant, $K_{AS} = K_1 = K_2 = K_3 = K_4$. With these substitutions, Equation A.5A.7 becomes:

$$r = \frac{2K_{AS}C_S}{1 + K_{AS}C_S}$$

Equation A.5A.8

which is the particular form ($p = 2$) of the general expression for a rectangular hyperbolic binding response, namely:

$$r = \frac{pK_{AS}C_S}{1 + K_{AS}C_S}$$

Equation A.5A.9

where p denotes the number of equivalent and independent ligand-binding sites on the acceptor. Because there is also widespread use of the definition of equilibrium constants in terms of dissociation ($K_d = 1/K_{AS}$), Equation A.5A.9 can also be written in the form:

$$r = \frac{pC_S}{K_d + C_S}$$

Equation A.5A.10

which bears obvious analogies to the Michaelis-Menten equation.

The general derivation of Equation A.5A.9 (e.g., Klotz, 1946; Winzor and Sawyer, 1995) is certainly more elegant than that presented here, but its reliance upon statistical considerations dictates the introduction of site equivalence and site independence as a combined assumption. The present treatment emphasizes that there are two separate assumptions, either of which may not be fulfilled. For example, binding sites may be independent but nonidentical—the situation encountered in the binding of protons to the amino and carboxyl groups of glycine. In addition to the possibility of acceptor-site heterogeneity, there may be sites that are equivalent ($K_1 = K_2$) but dependent ($K_1 \neq K_4$, $K_2 \neq K_3$)—the basis of a common concept of allostery (Koshland et al., 1966). However, violation of either assumption leads to binding curves that deviate from rectangular hyperbolic form. In Figure A.5A.1, the solid curve depicts the dependence of r upon C_S under conditions where both assumptions prevail, whereas the broken lines correspond to examples of acceptor site heterogeneity (- - -) and acceptor site cooperativity with $K_4 > K_1$ (– – –).

Rectangular hyperbolic responses abound in biology; in many cases the source can be traced to a single equilibrium binding event. There are situations where the parameter being monitored is the actual binding process. On the other hand, the kinetic characterization of an enzyme exhibiting Michaelis-Menten kinetic behavior provides an example where the rectangular hyperbolic dependence of the initial velocity (v) of product formation reflects the interactions of substrate with enzyme and the various enzyme-substrate complexes (ES, ES_2,.., ES_{p-1}). In present terms, the maximal velocity, V, is given by the product of the catalytic rate constant (k_c) and the total enzyme concentration ($\overline{C}_A$), whereupon the initial velocity is described by the relationship

BOSTON / CENTRAL UNIVERSITY LIBRARY

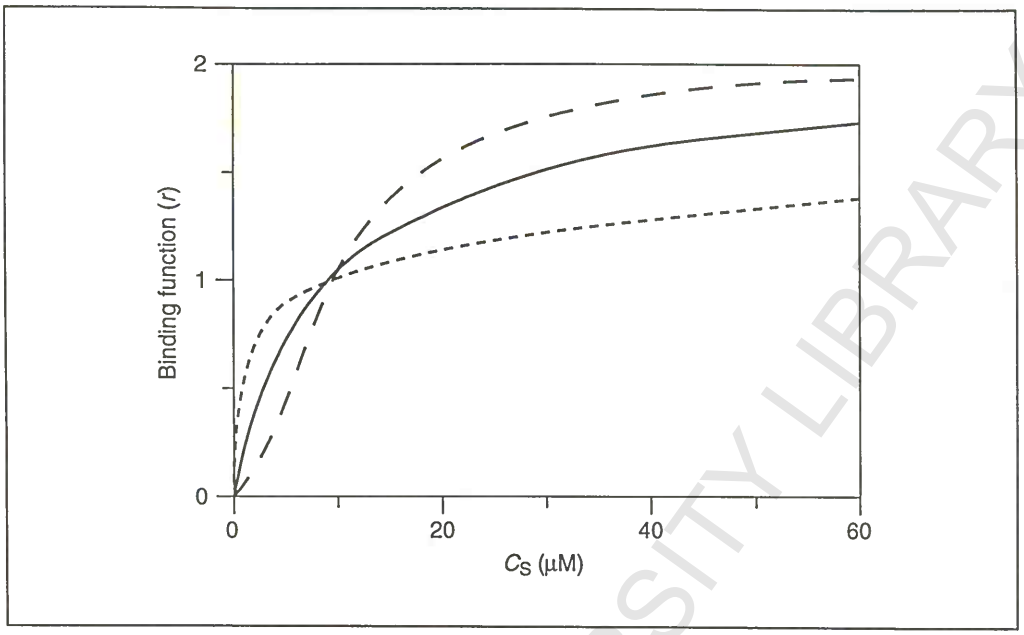

Figure A.5A.1 Illustrative dependences of the binding function (r) upon free ligand concentration (C_S) for various types of acceptor-ligand interaction. Rectangular hyperbolic dependence (——) for an acceptor with two equivalent and independent sites ($K_{AS} = K_1 = K_2 = K_3 = K_4 = 10^5\ M^{-1}$). Binding curve (- - -) for an acceptor with two independent but nonequivalent sites ($K_1 = K_4 = 10^6\ M^{-1}$; $K_2 = K_3 = 10^4\ M^{-1}$). Sigmoidal binding curve (– – –) for an acceptor with two equivalent but dependent sites ($K_1 = K_2 = 10^4\ M^{-1}$; $K_3 = K_4 = 10^6\ M^{-1}$). See Equations A.5A.1-A.5A.4 for equilibrium constant nomenclature.

$$v = k_c r \overline{C}_A = \frac{p k_c \overline{C}_A C_S}{K_M + C_S}$$

Equation A.5A.11

This emphasizes the fact that the catalytic rate constant and the Michaelis constant (K_M) are intrinsic parameters obtained on the basis of equivalent and independent substrate binding to the p active sites on the enzyme.

QUANTITATIVE CHARACTERIZATION OF A HYPERBOLIC RESPONSE

Quantitative characterization of a rectangular hyperbolic binding response entails the determination of two parameters, p and K_{AS}, in Equation A.5A.9. In the design of a binding experiment it is therefore important to adopt an experimental strategy that will maximize the accuracy with which those two parameters may be estimated from the measured dependence of the binding function (r) upon free ligand concentration (C_S).

Importance of Studying a Wide Range of Ligand Concentrations

The desired starting point in any binding analysis is a well-defined dependence of the binding function upon C_S. Under the equilibrium conditions of a binding assay, the magnitude of r approaches its maximum limiting value (p) very gradually with increasing free ligand concentration (Fig. A.5A.1). A wide range of C_S values is therefore required to extract accurate values of both p and K_{AS} from the form of the equilibrium binding curve. Whereas a linear scale in free ligand concentration crowds data at low C_S values because of substantial changes in r for small changes in free ligand concentration, a logarithmic scale in C_S turns the plot into a sigmoidal curve that is symmetrical about an

ACU IASI CENTRAL UNIVERSITY LIBRARY

inflection point at $r = p/2$. For rectangular hyperbolic binding, this inflection point provides an estimate of $K_d = 1/K_{AS}$. A change by one log unit (base 10) of C_S on each side of this inflection point covers a range of 10% to 90% acceptor saturation. Consequently, the dependence of r upon $\log_{10}C_S$ is an extremely useful means of assessing whether a sufficient range in r has been covered in the binding assay to allow accurate extraction of values of p and K_{AS} (Thompson and Klotz, 1971). The restriction of measurements to a narrow range of C_S, and hence of r, also renders difficult the detection of any deviation from rectangular hyperbolic behavior.

In situations where either the solubility or insufficiency of ligand precludes measurements of the upper portion of the binding curve, advantage may sometimes be taken of a change to experimental conditions that ensure essentially stoichiometric binding of ligand to acceptor. Such selection of conditions where the binding constant is sufficiently great for the acceptor-ligand mixtures to comprise complex and excess reactant (acceptor or ligand), the binding function (or a parameter related thereto) becomes linear in total ligand concentration to the titration endpoint, and independent of ligand concentration thereafter (Fig. A.5A.2A). Unequivocal determination of the reaction stoichiometry by this means or by use of subsidiary information, such as knowledge of the quaternary state of the acceptor, simplifies analysis of the binding data under equilibrium conditions (Fig. A.5A.2B) to the determination of a single parameter (K_{AS}), and hence enhances the accuracy with which the binding constant may be obtained from a suboptimal set of experimental results.

Nonlinear Least-Squares Methods

Direct fitting of untransformed data to the appropriate binding expression is the preferred method of evaluating binding parameters. Experimental binding data comprising (r, C_s) coordinate pairs can be fitted directly to Equation A.5A.9 by any of a number of nonlinear least-squares curve-fitting programs that are available in commercial software packages. Good programs allow the fitting equation to be defined by the user, and a choice of the parameters to be floated during the fitting procedure. The program should also provide estimates of the errors in the fitted parameters, as well as assessments of the goodness-of-fit in terms of chi-squared values and plots of the residuals. The first point on which the experimenter must decide is whether the data are indicative of a rectangular hyperbolic function. An objective test of the goodness-of-fit is provided by the value of chi squared. Visual inspection of the residuals plot should reveal a random scatter of experimental data about the fitted curve. Clearly, these tests require that there be sufficient data points or a sufficient sample size for statistical tests to be meaningful. For practical reasons this requirement is not met in many binding assays. However, for many spectroscopic titrations there is no impediment to collecting the required number of data points.

The experimenter should also be aware of the limitations of the fitting procedure. Most programs are based on a modified Marquardt algorithm, which may have difficulty converging to a minimum chi squared when initial estimates of the parameters are far removed from those associated with the least squares minimum. Moreover, the experimental points must cover a sufficient range of acceptor saturation. For example, programs experience difficulty returning accurate values of p and K_{AS} when experimental data are only available for a narrow range of acceptor saturation. Knowledge of the error associated with the estimates of both r and C_S is also important. Comparison of experimental results with simulated data for various values of K_{AS} (and possibly p) can be very useful for demonstrating the uniqueness of the fit obtained.

BOSTON CENTRAL UNIVERSITY LIBRARY

Use of Linear Transforms

Before the general availability of computers, linear transforms of the rectangular hyperbolic dependence of r upon C_S were used to determine values of p and K_{AS}. By simple algebraic manipulation, Equation A.5A.9 can be transformed into the following expressions:

$$r/C_S = pK_{AS} - rK_{AS}$$

Equation A.5A.12

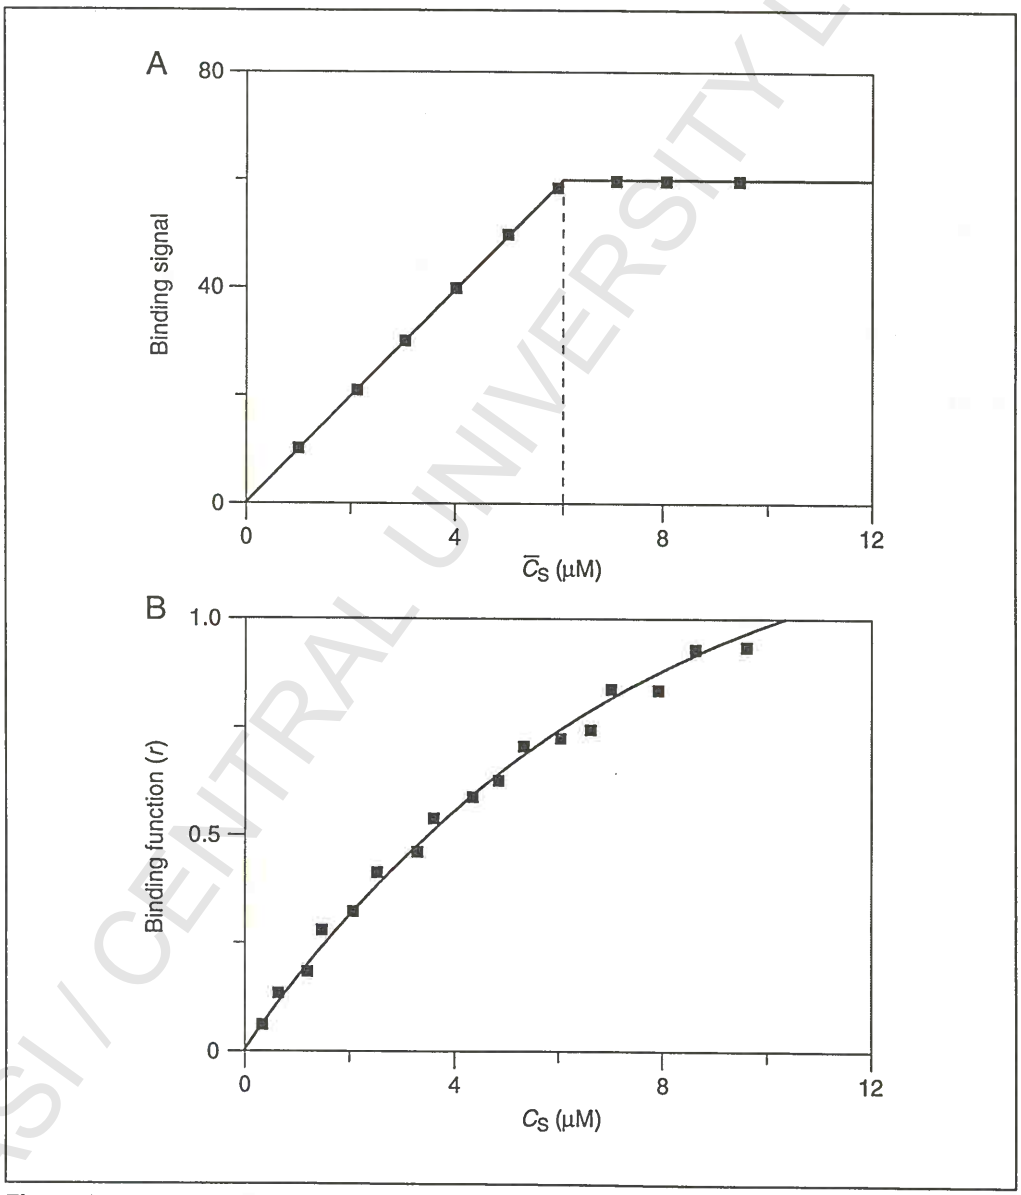

Figure A.5A.2 Illustrative characterization of an acceptor-ligand interaction for a system with limited ligand solubility. which lead to the graphical representations of data shown in Figure A.5A.3 (Scatchard plot, Hames plot, and double-reciprocal plot, respectively).

An undesirable characteristic of these plots is the bias introduced by the linear transformation. In the example given in Figure A.5A.3, the data become crowded towards the ordinate in the Hames and double-recip-

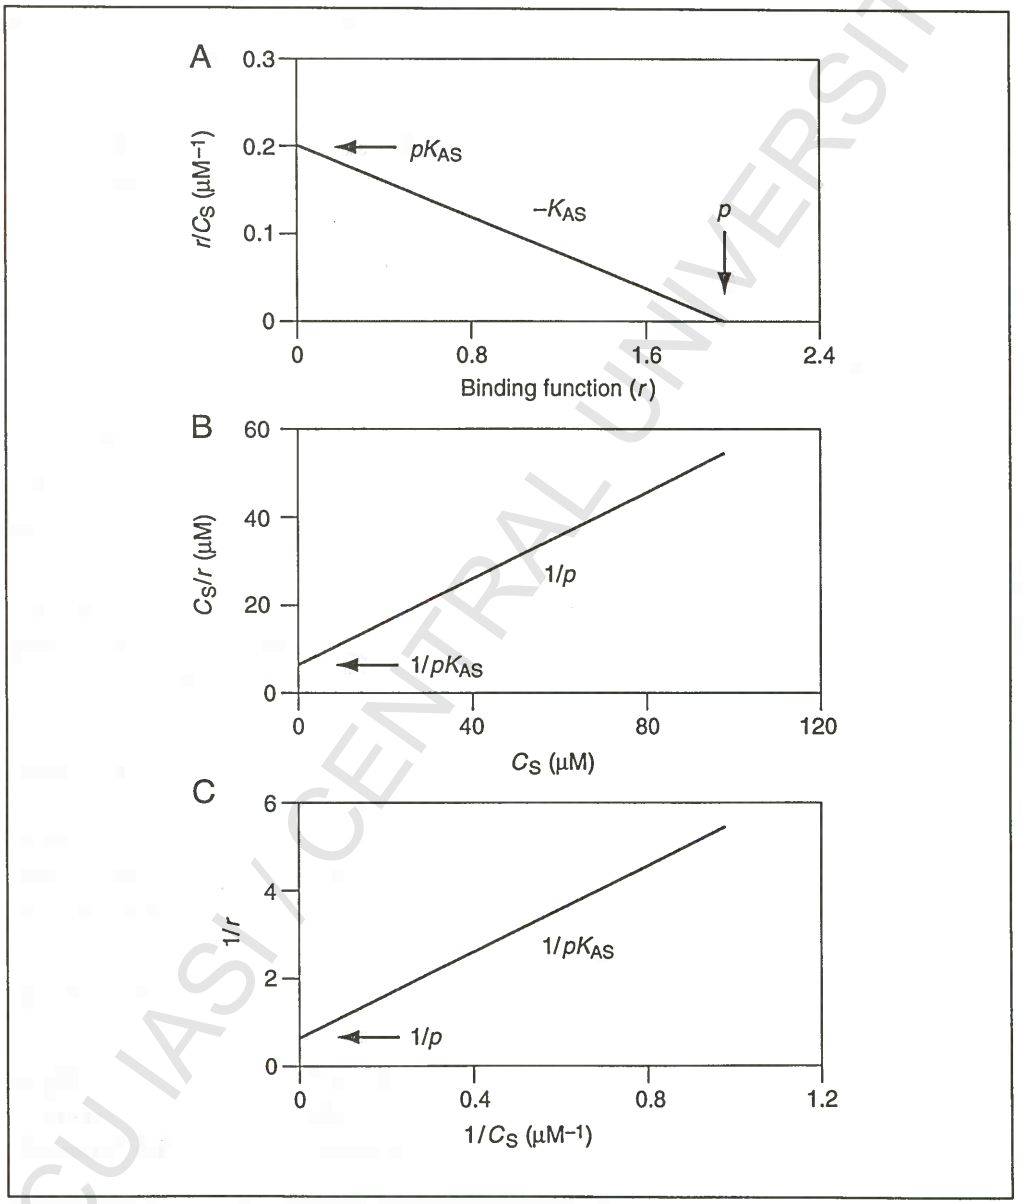

Figure A.5A.3 Use of various linear transforms (Equations A.5A.12-A.5A.14) of the rectangular hyperbolic binding equation to characterize an acceptor-ligand interaction with $p = 2$ and $K_{AS} = 10^5$ M^{-1}. (**A**) Scatchard plot; (**B**) Hames plot; (**C**) double-reciprocal plot.

DCU IAST / CENTRAL UNIVERSITY LIBRARY

rocal plots. This distortion of the primary data results in variable weighing of points in a linear regression analysis, a point addressed by Klotz (1983, 1997). The nonlinear least-squares fitting procedure circumvents this problem.

Despite the superiority of nonlinear least-squares fitting procedures for determining binding parameters, the plot of binding data in accordance with one of these linear transforms can still serve an important role in the analysis. First, the linearly transformed plot can assist in the decision about the adequacy of the simplest model with binding to equivalent and independent acceptor sites. More complex modes of binding give rise to deviations from rectagular hyperbolic responses (Fig. A.5A.1), and hence from linearity in the transformed manner of presentation. It is easier for the human eye to detect deviations from linearity than subtle deviations from a curvilinear dependence. Second, the linear transform is also useful for providing initial estimates of p and K_{AS} that are required by nonlinear least-squares fitting programs.

Experimental design summary

1. Use a semilogarithmic plot of r versus $\log_{10}C_S$ to establish the adequacy of the range of acceptor saturation covered by the experimental measurements (preferably 10% to 90%).
2. Know the limitations of the experimental method used for determining binding data. Determine the respective (r, C_S) coordinate pairs at least in triplicate to allow assessment of the uncertainty associated with each value of r.
3. Collect as many (r, C_S) coordinate pairs as practicable to allow the effective use of residuals plots and the statistical evaluation of chi squared.

Data analysis summary

1. Analysis of binding data aims, in the first instance, to identify and characterize the most appropriate binding model that is consistent with the experimental data.
2. The simplest model involves the binding of a ligand to equivalent and independent sites on a single acceptor, and results in the rectangular hyperbolic behavior described above. It is therefore the first model to be tested.
3. Deviations from rectangular hyperbolic behavior, detected by unsatisfactory curve fitting of the untransformed or transformed data to the simplest situation, indicate that more complex binding models must be considered (see Binding Responses Deviating from Rectangular Hyperbolic Form).
4. The formulation of a new binding model, together with its mathematical description, frequently requires consideration of complementary information about the acceptor-ligand system: whether the acceptor undergoes isomerization or self-association, whether there are noninteracting forms of the acceptor, whether the ligand is multivalent, and whether binding is enhanced or inhibited by other effector molecules that may be present.
5. Simulation of the mathematical model can be useful in guiding the design of further experiments.

The process of data analysis and interpretation is depicted diagrammatically in Figure A.5A.4. In that regard, it must be appreciated that agreement of the model with the experimental data does not establish the mechanistic legitimacy of the model, but merely the consistency between the two.

ILLUSTRATIVE ANALYSES OF EXPERIMENTAL RESULTS

The quantitative characterization of ligand binding is usually envisaged in terms of procedures based on measurement of the free ligand concentration (C_S) in mixtures with defined total composition ($\overline{C}_A$, $\overline{C}_S$). However, spectral studies afford the opportunity to measure the concentration of complexed ligand ($\overline{C}_S - C_S$), in mixtures with defined total composition. Inasmuch as the concentrations of free and complexed ligand are both required for quantitative analysis of ligand binding, there is no theoretical advantage associated with either type of procedure.

Methods Based on Measurement of Free Ligand Concentration

In methods such as equilibrium dialysis (Klotz, 1946), steady-state dialysis (Colowick and Womack, 1969; Ford et al., 1984), diafiltration (Blatt et al., 1968), and ultrafiltration (Sophianopoulos et al., 1978), a membrane that is permeable to ligand but not to acceptor is used to create a two-phase system in which one phase comprises the equilibrium mixture with composition ($\overline{C}_A$, $\overline{C}_S$) and the other an acceptor-free solution of ligand at a concentration related directly to its equilibrium concentration (C_S). Other methods that yield equivalent information include frontal gel chromatography on a matrix that excludes acceptor and hence all acceptor-ligand complexes (Nichol and Winzor, 1964), and liquid-liquid partition studies (Goodman, 1958). Provided that the ligand is sufficiently small that complex formation has no effect on the migration rate of the acceptor, analytical ultracentrifugation also has the potential to generate a sedimentation velocity pattern in which the slower-migrating boundary comprises free ligand at its equilibrium concentration (Steinberg and Schachman, 1966).

For the first illustration of the quantitative characterization of ligand binding by measurement of the free ligand concentration in mixtures with known total composition, consider the often-studied interaction between methyl orange and bovine serum albumin. The semilogarithmic plot (Fig. A.5A.5A) summarizes the original equilibrium dialysis data (Klotz et al., 1946) as well as subsequent results obtained by sedimentation velocity (Steinberg and Schachman, 1966). The inset to Figure A.5A.5A shows the double-reciprocal transform of the equilibrium dialysis data that was used to deduce values of 22 and 2,200 M^{-1} for p and K_{AS}, respectively (Klotz et al., 1946). Nonlinear least-squares analysis of the combined data sets (Fig. A.5A.5B) in terms of Equation A.5A.9 yields

(**A**) Semilogarithmic representation of the results, together with the double-reciprocal transform of the equilibrium dialysis data (inset). (**B**) Untransformed dependence of the binding function upon free ligand concentration, together with the best-fit description by nonlinear regression analysis according to Equation A.5A.9. respective estimates (at ±2 SD) of 27 ± 6 and 1900 ± 700 M^{-1} for the number of sites and the intrinsic binding constant. The relatively large extent of uncertainty associated with this quantitative analysis reflects the limited range of acceptor saturation (0.7% to 52%) covered by the binding measurements. Indeed, this deficiency of the data set is already manifested in the semilogarithmic plot, which shows no sign of the sigmoidal shape that indicates the coverage of a sufficient range of acceptor saturation for accurate definition of the affinity and stoichiometry of the interaction.

A second system is therefore used to better illustrate the potential of nonlinear least-squares analysis of binding data. The results of a frontal gel chromatographic study of the interaction between NADH and rabbit muscle lactate dehydrogenase (Ward and Winzor, 1983) have been supplemented with additional data to obtain the binding curve shown in Figure A.5A.6, which also establishes the sigmoidal shape of their representation in

CU IAS CENTRAL UNIVERSITY LIBRARY

semilogarithmic format (inset). The lines indicate the best-fit description obtained by nonlinear least-squares analysis, where $p = 4.01 \pm 0.04$ and $K_{AS} = 1.49\ (\pm 0.08) \times 10^5\ M^{-1}$, about which the experimental points exhibit random scatter (residuals plot in the upper panel). Inasmuch as the range of acceptor saturation ranges between 14.5% and 92.5%, these results exemplify the recommended experimental and analytical protocols that concluded the previous section.

Methods Based on Measurement of Complexed Ligand or Acceptor

Emphasis is now turned to binding procedures that rely upon the direct measurement of complex formation rather than on its deduction from knowledge of the total and free ligand concentrations. Because the extent of complex formation can be monitored by a response that emanates from either the acceptor or the ligand, there are two situations to consider.

A spectral signal arising from the acceptor

There are many examples in which a property of an acceptor is perturbed upon binding of a ligand. The property may be a biological activity, as in the case of an enzyme binding a substrate, or a biological response triggered by the occupation of a cell surface receptor. More commonly, a spectral property of the acceptor is changed upon ligand binding, thus providing a convenient method for following the binding reaction when the ligand is titrated into a solution of acceptor. The spectral change in the acceptor is a measure of the concentration of the ligand-acceptor complex ($\overline{C}_S - C_S$). Thus, the concentration of free

BOSTON UNIVERSITY CENTRAL LIBRARY

ligand must be found by difference between the total ligand concentration ($\overline{C}_s$) and that which is bound, ($\overline{C}_S - C_S$). Besides providing a means of following the binding equilibrium, the spectral change may also provide information about the chemical groups in the acceptor that are located at the acceptor-ligand interface.

The use of spectroscopic techniques to monitor binding equilibria requires careful attention to spectroscopic purity. Ideally, the spectroscopic signal should arise only from the acceptor species, so that the signal from the acceptor alone can be used to determine its concentration and ultimately the stoichiometry of the binding reaction. If the spectroscopic signal arises from two or more species, only one of which binds the ligand, the spectral change is overlaid on the background signal from the nonbinding species. The titration is still valid provided that the concentration of the binding form is accurately known. Particular problems arise when an acceptor is labeled with an extrinsic fluorescent probe. Labeling is rarely 100% efficient, and the labeled and unlabeled material may differ in their affinity for the ligand. Much time can be saved by separating the labeled from the unlabeled material before conducting binding experiments. Small amounts of background signal (e.g., solvent fluorescence or scattered excitation light in the case of fluorescence spectroscopy) can be dealt with by using appropriate controls and background subtraction.

The ultimate aim of biochemical study is to explain in vivo biochemistry at the molecular level. Consequently, the biochemist frequently proceeds from a controlled reductionist environment to a complex in vivo environment in which experimental rigor may be at least partially compromised. In these complex systems, high-resolution techniques such as nuclear magnetic resonance (NMR) and electron spin resonance (ESR) are particularly valuable, as they can discern a signal from a single acceptor or ligand within extremely heterogeneous solutions.

Assuming that each bound ligand causes an equivalent change in the spectroscopic signal, the fractional change in the spectroscopic parameter (f_A) is given by:

$$f_A = (y - y_f)/(y_b - y_f)$$

Equation A.5A.15

where y_b and y_f are the signals from the acceptor when sites are fully occupied (bound) and unoccupied (free), respectively. Conversion of the fractional saturation (f_A) to the binding function (r) requires knowledge of the number of binding sites on the acceptor (p), that is, the stoichiometry of the reaction. The stoichiometry is determined from a separate titration carried out at high acceptor levels such that each amount of ligand added is fully bound to the acceptor. This condition is accomplished when the acceptor concentration is ~100-fold greater than the dissociation constant ($K_{AS}\overline{C}_A = 100$), whereupon a plot of the fractional saturation against the ratio of total ligand to total acceptor ($\overline{C}_S/\overline{C}_A$) consists of two linear segments that intersect at the endpoint of the titration, thereby providing the stoichiometry (Fig. A.5A.7, line a). The condition $K_{AS}\overline{C}_A = 10$ provides a lower limit for discerning the two linear segments (Fig. A.5A.7, line b).

Once the stoichiometry has been determined, the binding curve can be evaluated from a titration in which the acceptor concentration is close to the dissociation constant for the binding equilibrium (Fig. A.5A.7, line c). The value of r is established at each value of C_S, whereupon the concentration of free ligand becomes:

PCU IASI CENTRAL UNIVERSITY LIBRARY

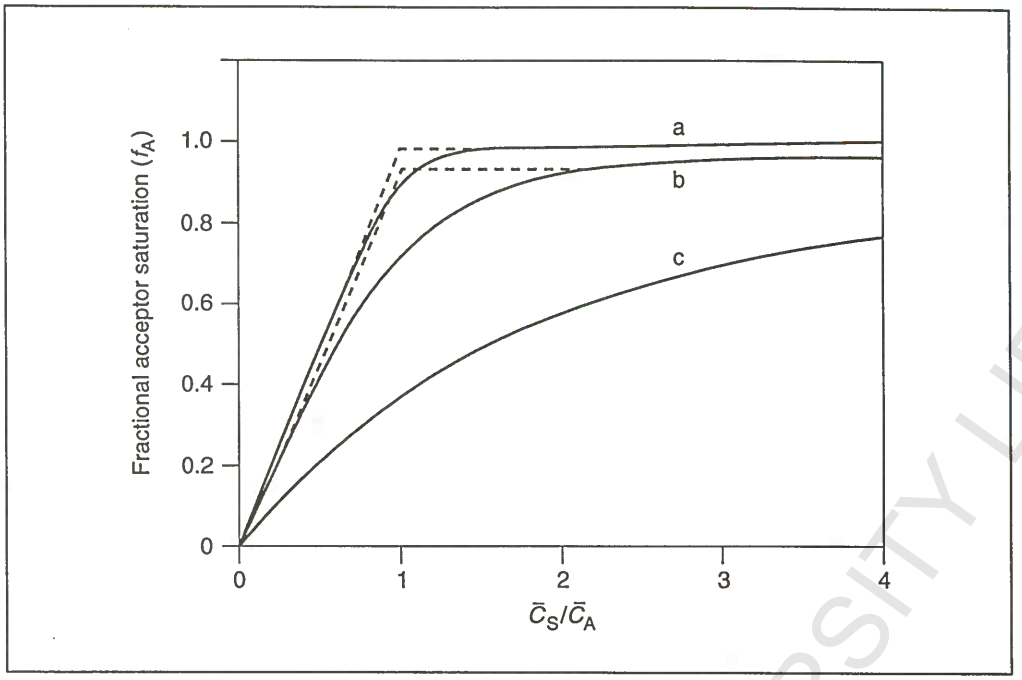

Figure A.5A.7 Evaluation of the stoichiometry of an acceptor-ligand interaction by stoichiometric titration. Curves have been constructed on the basis of a single acceptor site with a binding constant (K_{AS}) of 10^6 M^{-1} and total acceptor concentrations ($\bar{C}_A$) of 10^{-4} M (curve a), 10^{-5} M (curve b), and 10^{-6} M (curve c).

$$C_S = \bar{C}_S - r\bar{C}_A$$

Equation A.5A.16

The data are now plotted as r versus C_S or as one of the linear transforms described previously.

An example of this procedure is given by the binding of the *Escherichia coli* cAMP receptor protein to the primary site on the *lac* promoter (Heyduk and Lee, 1990). The stoichiometric titration in Figure A.5A.8A establishes the 1:1 stoichiometry, while the equilibrium titration in Figure A.5A.8B provides the data for generating the binding curve in Figure A.5A.8C. The binding analysis therefore requires two titrations—one under stoichiometric conditions, the other under equilibrium conditions.

A spectral signal arising from the ligand

Spectral properties of the ligand may be perturbed when it becomes bound to an acceptor. For example, changes may occur in the absorption or emission maximum, extinction coefficient, or circular dichroism ellipticity. The first step in binding analysis is determination of the spectral characteristics of the free and bound ligand. The characteristics of the free ligand (y_f) can be determined by direct measurement. Those of the bound ligand (y_b) can be determined by a separate titration in which acceptor is added to a solution of ligand. In the presence of excess acceptor all the ligand is bound. Plotting the data in double reciprocal form ($1/y$ versus $1/C_A$) allows the spectral property of the bound ligand to be discerned from the ordinate intercept. This plot is frequently assumed to be linear; however, examination of the theory shows that this need not be the case (Haigh and Sawyer, 1978). In the case of multiple equivalent or nonequivalent binding sites, it is assumed that the binding of each ligand results in an equivalent spectral change. A second titration is now carried out under equilibrium conditions in which a ligand is added to a

BOSTON CENTRAL UNIVERSITY LIBRARY

constant concentration of acceptor. The fraction of the ligand bound (f_S) may be found from the expression:

$$f_S = (y - y_f)/(y_b - y_f)$$

Equation A.5A.17

where y is the measured signal at a particular concentration of ligand. It then follows that

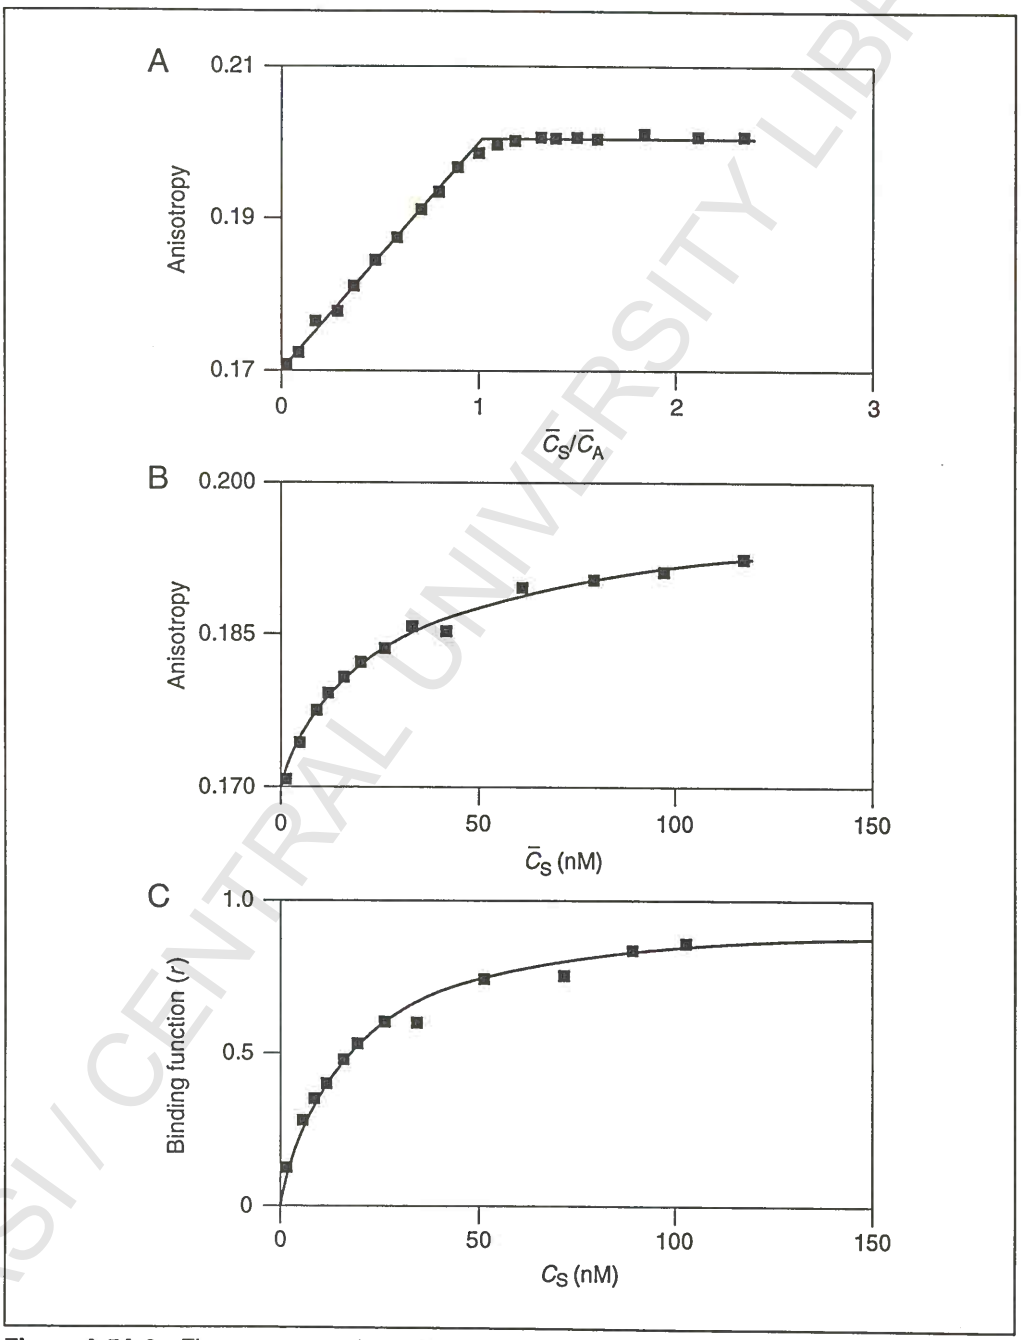

Figure A.5A.8 Fluorescence polarization (anisotropy) study of the interaction between *E. coli* cAMP receptor protein and a 32-bp DNA fragment of the *lac* promoter. (**A**) Stoichiometric titration of the fluorescently labeled DNA fragment with receptor protein in the presence of 0.2 mM cAMP. (**B**) Equilibrium titration in the presence of 0.5 μM cAMP. (**C**) Secondary plot of the equilibrium titration data as a binding curve, together with the best fit description ($p = 1$, $K_{AS} = 6.0 \times 10^7$ M^{-1}). Data taken from Heyduk and Lee (1990).

PCU IASI / CENTRAL UNIVERSITY LIBRARY

$$r = f_S \overline{C}_S / \overline{C}_A$$

Equation A.5A.18

$$C_S = \overline{C}_S - f_S \overline{C}_S$$

Equation A.5A.19

These calculations are repeated at each concentration of ligand added, so that the single titration provides the entire binding curve.

Alternative approaches

Other procedures have been devised for the analysis of spectroscopic binding data. The dilution titration (Anderson and Weber, 1965) can be applied to situations where the spectroscopic signal originates from either the acceptor or the ligand, and to situations where dilution of the acceptor does not cause any dissociation of an acceptor protein oligomer. An iterative procedure can be applied to situations involving equivalent and independent sites (Holbrook, 1972; Holbrook et al., 1972; Shanley et al., 1985). A model independent procedure, which avoids the restrictive assumption that each ligand causes an equivalent change in the spectroscopic signal, has been devised by Chatelier and Sawyer (1987).

Competitive Binding Assays

In addition to methods in which an acceptor-ligand interaction is monitored directly, there are also procedures wherein equilibrium parameters for the interaction of interest are inferred from the inhibitory effect of a competing ligand on an acceptor interaction that has already been characterized. Such competitive binding assays abound in the screening of drug and antigen analogs by solid-phase radioimmunoassay and enzyme-linked immunosorbant assay (ELISA) techniques, and also in the characterization of interactions by quantitative affinity chromatography (Winzor, 1997) and biosensor technology (Hall and Winzor, 1998). The analysis of competitive binding assays has been considered most extensively in the context of quantitative affinity chromatography, and is therefore presented in that light.

General theoretical aspects

In solid-phase competitive binding assays, the matrix-associated reactant (X) is chosen to obtain selective interaction with the solute of interest (acceptor A). For example, the interaction of antithrombin (A) with heparin (S) has been studied (Hogg et al., 1991) using heparin immobilized on Sepharose as the matrix-bound reactant (X). Ligand-facilitated elution of acceptor (A) from the matrix thus occurs because its interactions with ligand (S, soluble heparin) and matrix sites (X, immobilized heparin) are mutually exclusive (Fig. A.5A.9).

The first step of a competitive binding assay entails determination of the binding constant for the acceptor-matrix interaction (K_{AX}) and an associated curve-fitting parameter, the effective total concentration of matrix sites ($\overline{\overline{C}}_X$). Provided that A is univalent in its interaction with matrix sites, the extent of acceptor depletion from the liquid phase exhibits a rectangular hyperbolic dependence upon the acceptor concentration in the liquid phase ($\overline{C}_A$). For a mixture in which the total acceptor concentration in the system is $\overline{\overline{C}}_A$, the rectangular hyperbolic dependence may be written in the form

BOURKE / GEORGIA UNIVERSITY LIBRARY

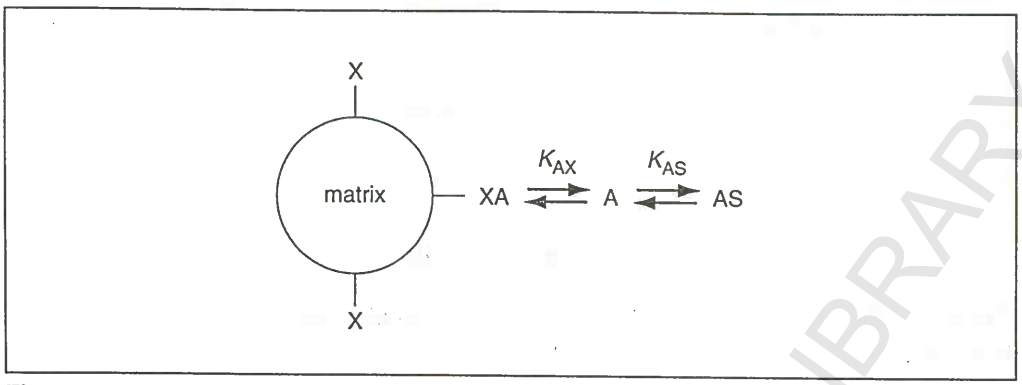

Figure A.5A.9 Schematic representation of the competitive interactions of soluble ligand (S) and immobilized affinity sites (X) for acceptor (A) in quantitative affinity chromatography.

$$\overline{\overline{C}}_A - \overline{C}_A = K_{AX}\,\overline{\overline{C}}_X\,\overline{C}_A/(1+K_{AX}\overline{C}_A)$$

Equation A.5A.20

of which the most convenient version of the Scatchard linear transform is

$$\left(\overline{\overline{C}}_A/\overline{C}_A\right)-1 = K_{AX}\overline{C}_X - K_{AX}\overline{C}_A\left[\left(\overline{\overline{C}}_A/\overline{C}_A\right)-1\right]$$

Equation A.5A.21

Expression of the Scatchard transform in that manner allows its ready adaptation to column chromatographic data, for which the ratio $\overline{\overline{C}}_A/\overline{C}_A$ may be replaced by $\overline{V}_A/V_A{}^*$, where $\overline{V}_A$ is the measured elution volume of acceptor on an affinity column for which $V_A{}^*$ is the corresponding elution volume in the absence of any acceptor-matrix interaction (the elution volume of ligand-saturated A). For frontal chromatographic studies, the counterpart of Equation A.5A.21 thus becomes (Hogg and Winzor, 1984)

$$\left(\overline{V}_A/V_A^*\right)-1 = K_{AX}\,\overline{\overline{C}}_X - K_{AX}\overline{C}_A\left[\left(\overline{V}_A/V_A^*\right)-1\right]$$

Equation A.5A.22

Upon supplementation of the liquid phase with a free concentration (C_S) of competing ligand, the rectangular hyperbolic dependence of ($\overline{\overline{C}}_A - \overline{C}_A$) upon $\overline{C}_A$ continues to be described by Equation A.5A.20, except that the acceptor-matrix binding constant so determined is a constitutive parameter ($\overline{K}_{AX}$) that is related to K_{AX} by the relationship (Winzor and Jackson, 1993)

$$Q = K_{AX}/\overline{K}_{AX} = 1 + K_{AS}C_S$$

Equation A.5A.23

The binding constant for the competing acceptor-ligand interaction in solution (K_{AS}) may therefore be obtained from the linear dependence of the ratio of acceptor-matrix binding constants (Q) upon free ligand concentration. In instances where the total ligand concentration ($\overline{C}_S$) is the parameter of known magnitude, Equation A.5A.23 is replaced by the expression

CU IASI / BIBLIOTECA UNIVERSITARA LIBRARY

$$Q = 1 + K_{AS}\left[q\overline{C}_S - (Q-1)\overline{C}_A/Q\right]$$

Equation A.5A.24

where q is the valence of S in its interaction with A, a consideration necessitated by the enforced design of the experiment whereby A must be univalent in its interaction with matrix sites X. The problem of allowing A to be multivalent is addressed later.

Partition equilibrium variants of quantitative affinity chromatography

The most direct method of employing Equation A.5A.20 or A.5A.21 is to perform simple partition equilibrium experiments on matrix-acceptor mixtures (with or without S). Measurement of the liquid-phase concentration of A after attainment of equilibrium allows the concentration of matrix-bound solute to be determined as the difference between the total acceptor concentration in the matrix slurry and its corresponding concentration in the liquid phase (Nichol et al., 1974). The problem of ensuring that each mixture contains the same amount of affinity matrix can frequently be overcome by using a recycling partition technique (Ford and Winzor, 1981; Hogg et al., 1991) in which the liquid-phase concentration of acceptor ($\overline{C}_A$) is monitored spectrophotometrically by means of a flow cell placed in the line returning the liquid phase to the slurry (Fig. A.5A.10A). This procedure has the advantage that a number of partition experiments may be performed with the same sample of matrix by making successive additions of concentrated acceptor solution to the slurry and determining the corresponding value of $\overline{C}_A$ after each addition. The dilution of the concentration of affinity sites ($\overline{\overline{C}}_X$) arising from the stepwise addition of acceptor (and ligand) aliquots with volume δV is accommodated by multiplying each ($\overline{\overline{C}}_A - \overline{C}_A$) result by $V_A^*/(V_A^*)_0$: the relevant volume accessible to A after n such additions (V_A^*) is calculated from the initial value $(V_A^*)_0$ and the relationship $V_A^* = (V_A^*)_0 + n\delta V$. A Scatchard representation of results obtained by this technique for the interaction of antithrombin with heparin-Sepharose (Hogg et al., 1991) is presented in Figure A.5A.10B.

Column chromatographic variants

Inspection of Equation A.5A.22 shows that knowledge of $\overline{C}_A$, the concentration of acceptor in the liquid phase, is a prerequisite for its application to elution profiles obtained by applying acceptor solution (or acceptor-ligand mixture) to an affinity column. However, there have been relatively few chromatographic studies in which the full potential of Equation A.5A.22 has been put to advantage (Winzor, 1997). Far greater use has been made of zonal chromatography, where the lack of a value of $\overline{C}_A$ dictates the truncation of Equation A.5A.22 to:

$$\left(\overline{V}_A/V_A^*\right) - 1 = K_{AX}\,\overline{\overline{C}}_X$$

Equation A.5A.25

which involves the assumption that the total concentration of matrix sites is an acceptable substitute for their free concentration (Bergman and Winzor, 1986). Subject to the validity of that approximation, zonal chromatography of the solute on an affinity column preequilibrated with a range of concentrations of competing ligand (C_S) allows the acceptor-ligand binding constant to be evaluated from the expression

BCU ARSI / CENTRAL UNIVERSITY LIBRARY

$$\left(\overline{V}_A/V_A^*\right)-1=K_{AX}\,\overline{\overline{C}}_X/\left(1+K_{AS}C_S\right)$$

Equation A.5A.26

in which K_{AS} and the product $K_{AX}\overline{\overline{C}}_X$ are the two parameters to be obtained by curve fitting. Further details of this procedure, introduced by Dunn and Chaiken (1974), are to be found in a recent review of quantitative affinity chromatography (Winzor, 1997).

Biosensor studies of ligand binding

An alternative means of quantifying the interaction between acceptor and matrix sites is to directly monitor the concentration of matrix-bound A in an equilibrium mixture by

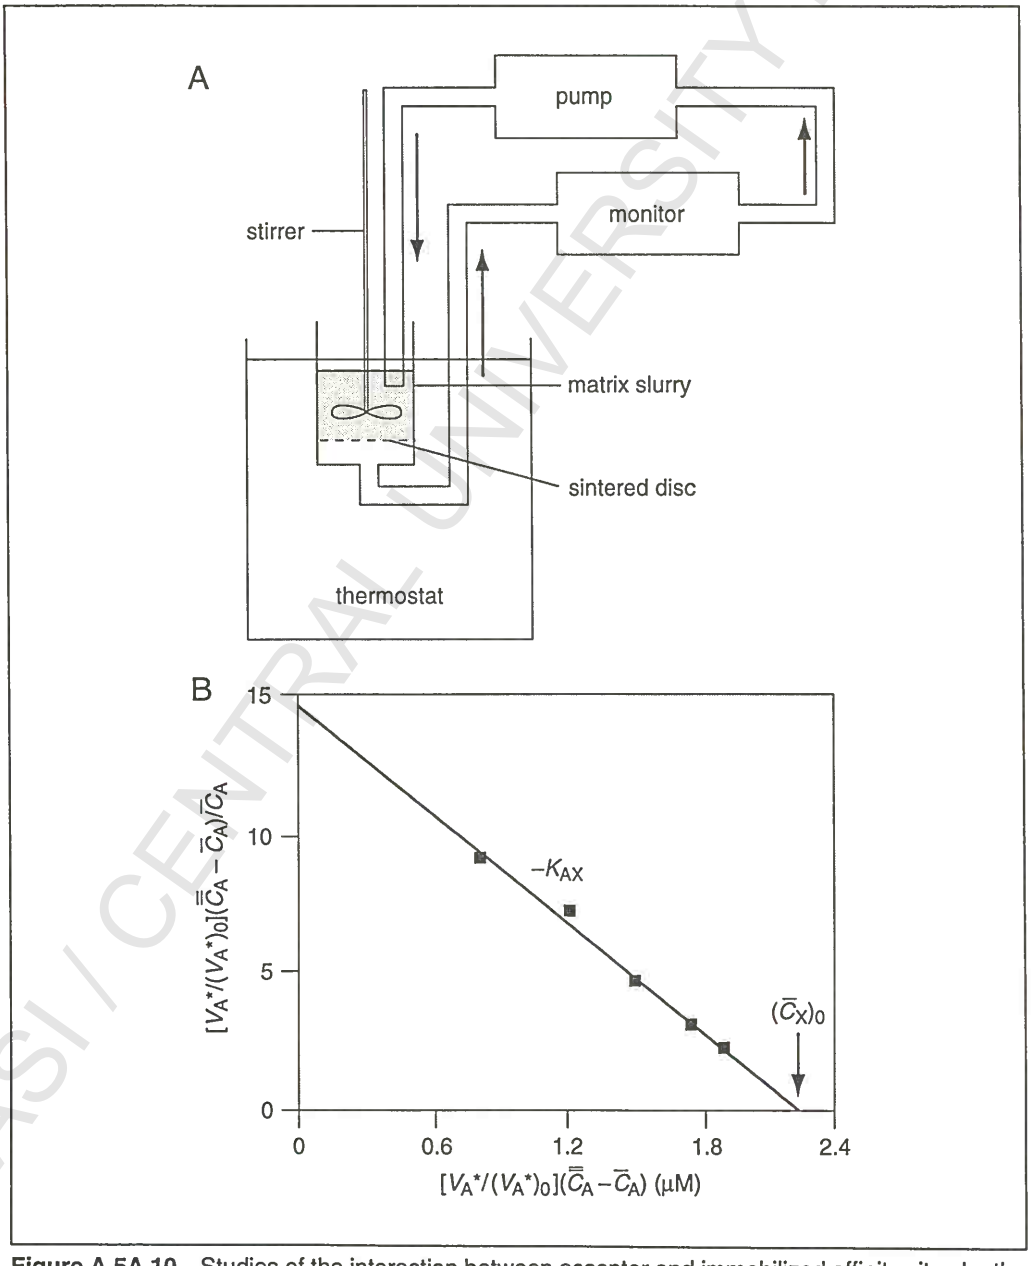

Figure A.5A.10 Studies of the interaction between acceptor and immobilized affinity sites by the recycling partition variant of quantitative affinity chromatography. (**A**) Schematic representation of the experimental system. (**B**) Scatchard plot of results obtained for the interaction of antithrombin with heparin-Sepharose (Hogg et al., 1991).

PCU IASI / CENTRAL UNIVERSITY LIBRARY

biosensor technologies such as those incorporated into the BIAcore and IAsys instruments. Although the major interest in biosensor-based instruments has been their use to determine the kinetics of adsorption and desorption for the acceptor-matrix interaction, attention has also been drawn to the potential of their application in the context of quantitative affinity chromatography (Ward et al., 1995; Hall and Winzor, 1997, 1998).

In the BIAcore instrumentation, a solution of acceptor flows through a capillary channel over the biosensor chip, which has been rendered an affinity matrix by the covalent attachment of affinity sites X. Because the solution in contact with the sensor surface is being replaced continually by fresh solution, the time-independent response that is ultimately attained (R_e) is directly proportional to the concentration of bound acceptor ($\overline{\overline{C}}_A - \overline{C}_A$) in equilibrium with $\overline{C}_A$, the concentration of acceptor in the solution being injected into the instrument. Measurement of R_e as a function of injected acceptor concentration ($\overline{C}_A$) allows K_{AX} to be determined from the expression

$$R_e = K_{AX}\left(B\overline{\overline{C}}_X\right)\overline{C}_A/\left(1+K_{AX}\overline{C}_A\right)$$

Equation A.5A.27

which is essentially a rearranged form of Equation A.5A.20 with ($\overline{\overline{C}}_A - \overline{C}_A$) replaced by R_e/B, where B is the proportionality constant relating biosensor response to bound acceptor concentration. The other parameter to emerge from curve fitting of the (R_e, $\overline{C}_A$) data to this rectangular hyperbolic expression is the product $B\overline{\overline{C}}_X$, the maximum response corresponding to saturation of all affinity sites.

The equilibrium constant for the interaction between acceptor and a competing ligand (S) is then obtained by injecting acceptor-ligand mixtures with a range of total concentrations of competitive inhibitor ($\overline{C}_S$). Because the magnitude of $B\overline{\overline{C}}_X$ has already been established, the substitution of each (R_e, $\overline{C}_A$, $\overline{C}_S$) combination into Equation A.5A.27 yields the value of K_{AX} pertinent to Equation A.5A.24. K_{AS} is then evaluated from the slope of the dependence of $Q = K_{AX}/K_{AX}$ upon $[q\overline{C}_S - (Q-1)\overline{C}_A/Q]$.

Analysis of results obtained from the IAsys instrument follows essentially the same protocol, except that $\overline{C}_A$ in Equation A.5A.27 is not the concentration of acceptor placed in the cuvette, because allowance needs to be made for acceptor depletion as the result of AX formation. Thus, the value of $\overline{C}_A$ for use in Equation A.5A.27 (and Equation A.5A.24) must be obtained from the relationship $\overline{C}_A = (\overline{C}_A)_0 - R_e/B$, where $(\overline{C}_A)_0$ is the concentration of acceptor placed in the cuvette at the start of the measurement (Hall and Winzor, 1997, 1998; Edwards et al., 1998).

Illustrative evaluation of K_{AS} by competitive binding assay

The evaluation of the equilibrium constant for an acceptor-ligand interaction by competitive binding assay is illustrated here using a BIAcore study of the interaction between interleukin 6 and the soluble form of its specific receptor (Ward et al., 1995). The recombinant cytokine proved to be dimeric, and has therefore been attached to the biosensor surface so that results could be interpreted in terms of Equation A.5A.27 with the soluble receptor as the univalent acceptor (A). Characterization of the acceptor-matrix interaction is summarized in Figure A.5A.11A, which presents the results in Scatchard format. Values of 2.4 ($\pm$ 0.2) $\times 10^7$ M^{-1} and 2200 ($\pm$ 100) response units are obtained for K_{AX} and the product $B\overline{\overline{C}}_X$, respectively. Results from the series of experiments on mixtures of acceptor and interleukin 6 are plotted in Figure A.5A.11B according to Equation A.5A.24, with $q = 2$ because of the dimeric nature of the cytokine. A value of 4.8 ($\pm$ 0.3) $\times 10^7$ M^{-1} is obtained from the slope.

BRUNEL CENTRAL UNIVERSITY LIBRARY

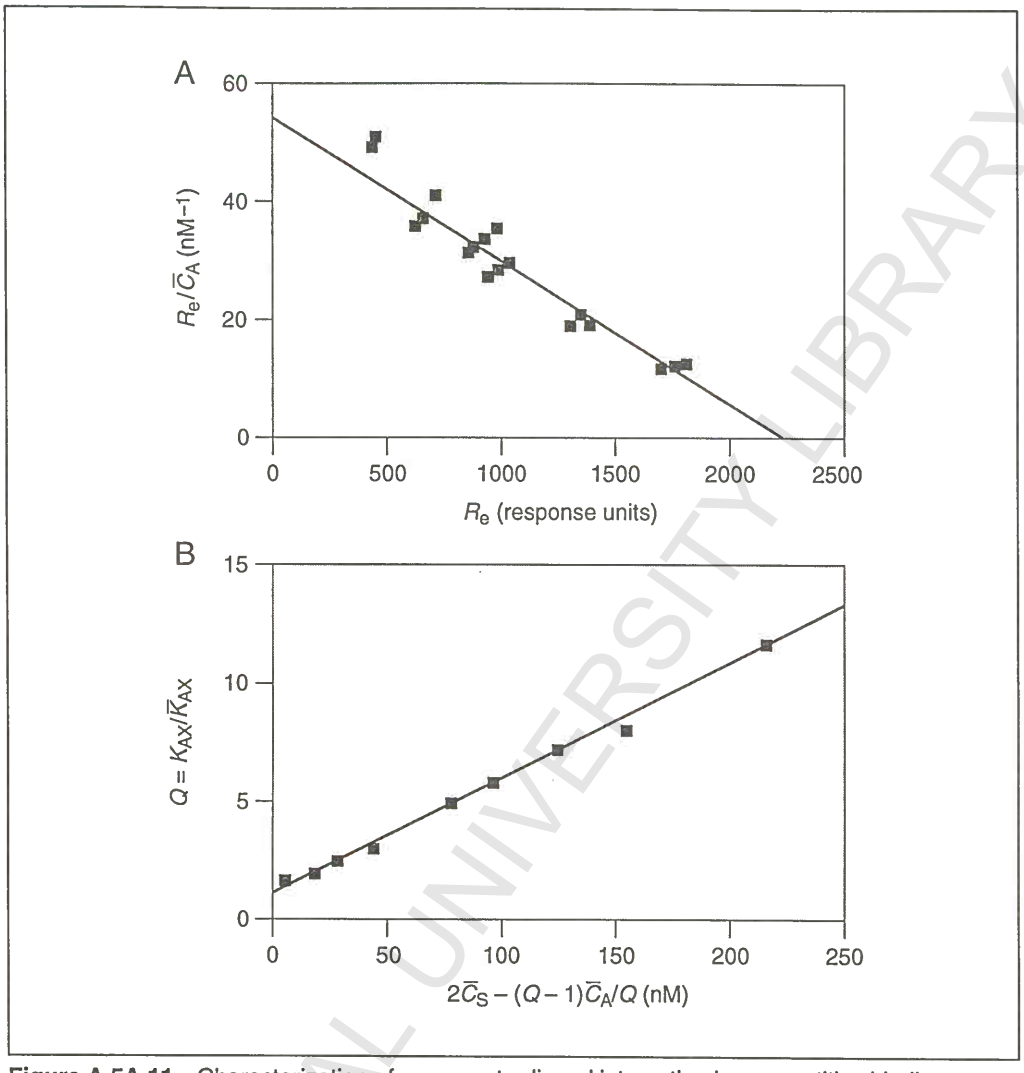

Figure A.5A.11 Characterization of an acceptor-ligand interaction by competitive binding assay. (**A**) Scatchard plot of equilibrium responses for the interaction of the soluble domain of interleukin 6 receptor (A) with interleukin 6 immobilized on the sensor surface of a BIAcore instrument. (**B**) Plot of results obtained with interleukin 6 as the competing ligand (S) in accordance with Equation A.5A.24, with $q = 2$. Data taken from Ward et al. (1995).

This use of BIAcore data to illustrate the evaluation of equilibrium constants by competitive binding assay is open to criticism on the grounds that partition or chromatographic studies are more traditional forms of quantitative affinity chromatography. However, the selected example serves an important role by emphasizing the assumed univalence of acceptor in the analysis, and by illustrating one means by which the problem of multivalence can be averted. An alternative approach is discussed in the next section.

BINDING RESPONSES DEVIATING FROM RECTANGULAR HYPERBOLIC FORM

It has already been emphasized that the rectangular hyperbola represents the simplest form of binding response, and that deviations therefrom signify the need for the incorporation of additional complexity into the model to account for the shape of the binding curves. Possible sources of deviation from the form shown as the broken line (- - -) in Figure A.5A.1 are considered below.

ECU IASTI CENTRAL UNIVERSITY LIBRARY

Effect of Acceptor Site Heterogeneity

Equations A.5A.1-A.5A.4 have been used to describe a model involving ligand interaction with two equivalent and noninteracting acceptor sites; this model can now be extended to a situation in which the two binding sites are nonequivalent but still independent. Independence means that the binding constant for one site is the same regardless of whether the other site is occupied or not. Thus, in terms of Equations A.5A.1-A.5A.4, $K_1 = K_4$ and $K_2 = K_3$. A rearrangement of Equation A.5A.7 shows that the binding to two nonequivalent and independent sites is described by the sum of two rectangular hyperbolae.

$$r = \frac{K_1 C_S (1 + K_2 C_S) + K_2 C_S (1 + K_1 C_S)}{(1 + K_1 C_S)(1 + K_2 C_S)}$$

Equation A.5A.28

$$r = \frac{K_1 C_S}{(1 + K_1 C_S)} + \frac{K_2 C_S}{(1 + K_2 C_S)}$$

Equation A.5A.29

For two nonequivalent groups of sites (p and q in each group) the general binding equation becomes

$$r = \frac{pK_1 C_S}{(1 + K_1 C_S)} + \frac{qK_2 C_S}{(1 + K_2 C_S)}$$

Equation A.5A.30

which may be used directly in nonlinear least-squares fitting programs to extract estimates of the two binding constants and the two site numbers. The corresponding Scatchard plot is nonlinear and of the form shown in Figure A.5A.12. Here, the deviation from linearity is useful in recognizing that a simple model involving homogeneous sites is inadequate to describe the experimental data. For a more quantitative analysis, the Scatchard plot is of limited use. A common misconception is that the limiting slopes of this graph provide estimates of the two binding constants while their extrapolation to the abscissa provides the respective site numbers. This difficulty is illustrated in Figure A.5A.12, which shows the Scatchard plots for a binding model involving two independent sites that differ in affinity by factors of 2, 10, and 100. The Scatchard plots for the binding to each independent site are included. The following features are apparent:

1. The Scatchard plot is not the simple sum of the plots describing the individual site contributions.
2. The abscissa intercept represents the total site number (in this case two), but becomes more difficult to determine graphically as the difference between the binding affinities increases.
3. When the binding affinities differ by a factor of two, it becomes very difficult to experimentally identify the deviation from linearity and thus the site heterogeneity.
4. As the difference between the binding affinities increases, the limiting slope of the steepest part of the Scatchard plot provides an estimate of the tighter binding constant.

BOUVET / CENTRAL UNIVERSITY LIBRARY

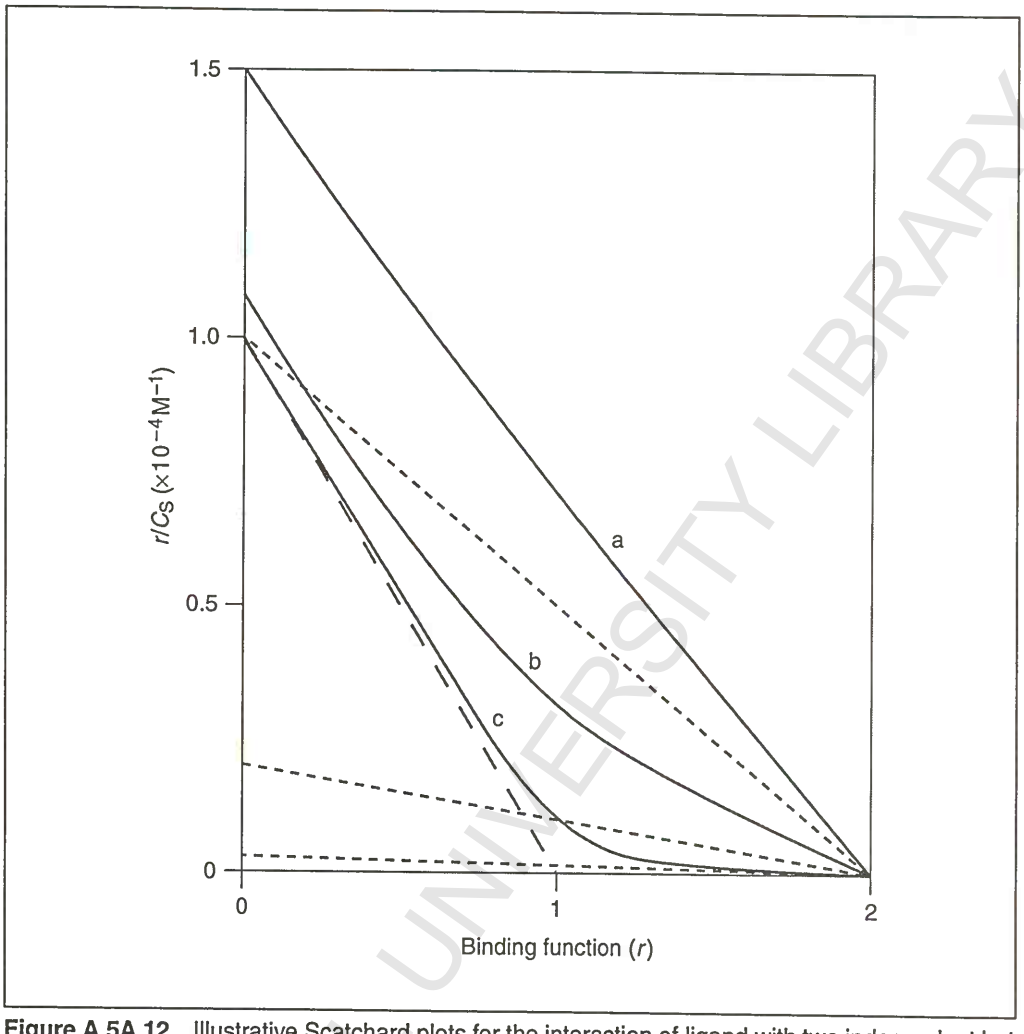

Figure A.5A.12 Illustrative Scatchard plots for the interaction of ligand with two independent but nonequivalent acceptor sites. The higher-affinity site has been ascribed a binding constant of 10^5 M^{-1}, whereas the other has been accorded values of 5×10^4 M^{-1} (curve a), 10^4 M^{-1} (curve b), and 10^3 M^{-1} (curve c). The broken line describes the interaction of ligand with the higher-affinity binding site, whereas the dotted lines have a common abscissa intercept of 2 and slopes characteristic of the weaker interactions.

However, as has been carefully documented by Klotz (1997), the limiting slopes and intercepts at high and low values of r are complex functions of the two binding constants and site numbers.

5. Besides the difficulty of extracting the binding parameters graphically from the Scatchard plot, it should be recognized that a similar deviation from linearity is observed in cases where multiple sites interact in a negatively cooperative manner.

A slightly different situation arises when the two groups of sites (p and q) are on two different noninteracting molecules (A and B) rather than on the same molecule. In addition to being determined by the binding affinities and site numbers (K_{AS}, K_{BS}, p, q), the binding function is determined by the mole fraction (α_i) of each acceptor species present: $\alpha_A = \overline{C}_A/(\overline{C}_A + \overline{C}_B)$ and $\alpha_B = (1 - \alpha_A) = \overline{C}_B/(\overline{C}_A + \overline{C}_B)$, where the overbar notation again signifies the total concentration (free and complexed) of a given acceptor. In these circumstances

PCU IASI / CENTRAL UNIVERSITY LIBRARY

$$r = \frac{\alpha_A p K_{AS} C_S}{(1 + K_{AS} C_S)} + \frac{(1 - \alpha_A) q K_{BS} C_S}{(1 + K_{BS} C_S)}$$

Equation A.5A.31

where

$$\alpha_A = \frac{C_A (1 + K_{AS} C_S)^p}{C_A (1 + K_{AS} C_S)^p + C_B (1 + K_{BS} C_S)^q}$$

Equation A.5A.32

Effect of Ligand Multivalence

A limitation of the binding equations presented thus far has been their reliance upon the assumption that the ligand is univalent in its interaction with acceptor sites. Although the use of those binding equations is entirely reasonable for systems in which the ligand is a small, unifunctional metabolite, the validity of their application to (for example) the interactions of antibodies with their specific surface antigens is highly questionable. The problem is that ligand multivalence introduces a deviation from the rectangular hyperbolic response that is of the same form as that for binding of a univalent ligand to heterogeneous acceptor sites (Calvert et al., 1979). Effects of ligand multivalence on the interpretation of binding data were first considered in the context of quantitative affininty chromatography (Nichol et al., 1981), but have been incorporated subsequently into a general counterpart of the Scatchard analysis (Hogg and Winzor, 1985).

For a situation in which a ligand possessing f sites binds to an acceptor with p sites for ligand, the binding function needs to be defined (Hogg and Winzor, 1985) as

$$r_f = \left(\overline{C}_S^{1/f} - C_S^{1/f}\right) / \overline{C}_A$$

Equation A.5A.33

In terms of this binding function, the multivalent counterpart of the Scatchard equation for equivalent and independent binding governed by the intrinsic association constant K_{AS} is

$$r_f / C_S^{1/f} = pK_{AS} - fK_{AS} r_f \overline{C}_S^{(f-1)/f}$$

Equation A.5A.34

A linear dependence of $r_f / C_S^{1/f}$ upon $r_f \overline{C}_S^{(f-1)/f}$ is thus the requirement for equivalence and independence of sites when the ligand is multivalent.

Because the application of Equation A.5A.34 to binding data requires the specification of a value for f, there has been a tendency to avoid the necessity of so doing by retaining the conventional Scatchard analysis (Equation A.5A.12). However, such action merely signifies that a value of unity has been chosen as the most appropriate valence of the ligand. Results from a partition equilibrium study of the binding of aldolase to muscle myofibrils (Kuter et al., 1983) serve to emphasize that point. The conventional Scatchard analysis of those results is presented in Figure A.5A.13A, which seemingly signifies heterogeneity of the myofibrillar sites in their interaction with enzyme. However, symptoms of site heterogeneity disappear on reanalysis of the results according to Equation

BOSTON CENTRAL UNIVERSITY LIBRARY

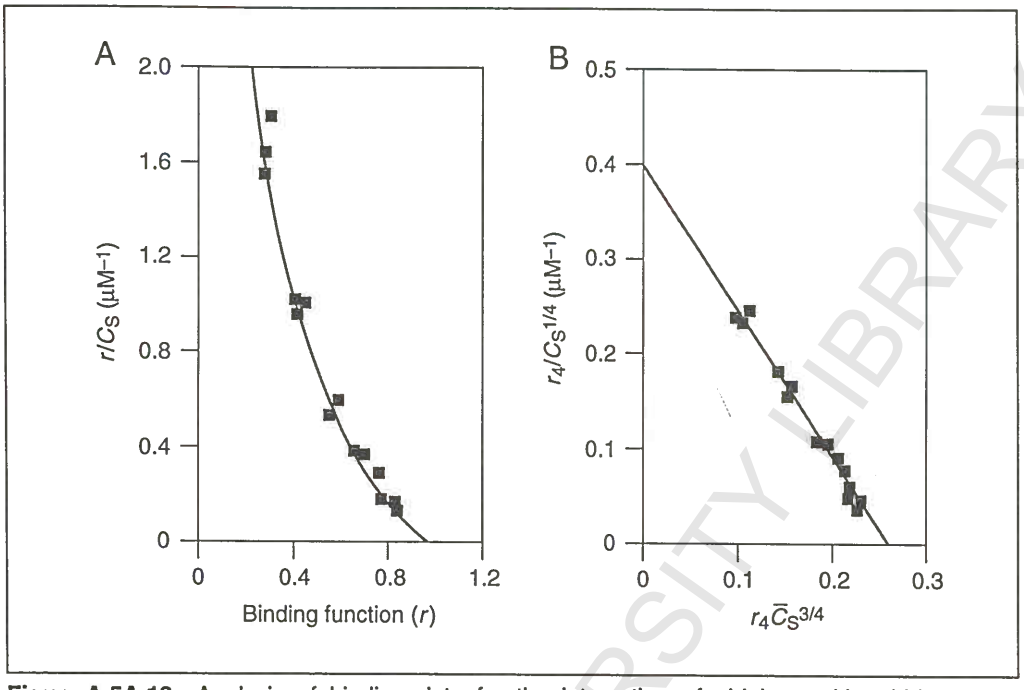

Figure A.5A.13 Analysis of binding data for the interaction of aldolase with rabbit muscle myofibrils. (**A**) Conventional Scatchard plot. (**B**) Multivalent Scatchard plot according to Equation A.5A.34 with $f = 4$. Data taken from Table 1 of Kuter et al. (1983).

A.5A.34 with $f = 4$ on the grounds that aldolase is a tetramer (Fig. A.5A.13B). The linearity of this plot, particularly in the light of its compliance with the mandatory abscissa intercept of 0.25 (p/f with $p = 1$), establishes the adequacy of a single intrinsic binding constant of 3.8 (± 0.3) × 10^5 M^{-1} to describe the binding of tetravalent enzyme to sites on the myofibrillar matrix.

Although this analysis is open to criticism on the grounds of its reliance upon transformed experimental parameters, the finding has been confirmed by analysis of the results in terms of the rectangular hyperbolic expression of which Equation A.5A.34 is the linear transform (Harris et al., 1995a). Use of the expression

$$fr_f\bar{C}_S^{(f-1)/f} = \frac{pf\bar{C}_S^{(f-1)/f}K_{AS}C_S^{1/f}}{1+f\bar{C}_S^{(f-1)/f}K_{AS}C_S^{1/f}}$$

Equation A.5A.35

allows the magnitudes of p and K_{AS} to be obtained by substituting $fr_f\bar{C}_S^{(f-1)/f}$ for r and $f\bar{C}_S^{(f-1)/f}C_S^{1/f}$ for C_S in standard computer programs for the evaluation of binding parameters.

In studies of binding to a particulate acceptor there are circumstances under which a rectangular hyperbolic binding response is observed despite multivalence of the ligand (Nichol et al., 1974; Brinkworth et al., 1975)—a finding rationalized intuitively at the time on the grounds that physical restrictions precluded multiple interactions of ligand with acceptor. That the binding constant deduced under such circumstances is the product fK_{AS} has been confirmed by a subsequent mathematical explanation of such behavior (Kalinin et al., 1995), which arises when the total concentration of ligand greatly exceeds that of acceptor sites. Under conditions where the concentration of bound ligand ($\bar{C}_S$ –

CU IAS/CENTRAL UNIVERSITY LIBRARY

C_S) is small relative to the free concentration (C_S), the total ligand concentration $\overline{C}_S$ may be written as:

$$\overline{C}_S = C_S + (\overline{C}_S - C_S) = C_S(1+\delta)$$

Equation A.5A.36

where $\delta = (\overline{C}_S - C_S)/C_S$ is much smaller than unity. From the binomial theorem it follows that

$$\overline{C}_S^{1/f} = C_S^{1/f}(1+\delta/f+\ldots)$$

Equation A.5A.37

whereupon the binding function (Equation A.5A.33) becomes $r_f = C_S{}^{1/f}\delta/(f\overline{C}_A)$, and Equation A.5A.34 simplifies to

$$(\overline{C}_S - C_S)/C_S = fK_{AS}\overline{C}_A - fK_{AS}(\overline{C}_S - C_S)[1+(f-1)\delta/f]$$

Equation A.5A.38

which signifies a slope of $f[1 + (f - 1)\delta/f]K_{AS} \approx fK_{AS}$ for the slope of the conventional Scatchard plot.

Equivalent but Cooperative Binding

In instances where the acceptor comprises several identical (or very similar) subunits, the binding of a univalent ligand to any one subunit has the potential to induce conformational changes in adjacent subunits and thereby alter their intrinsic affinities for ligand. This concept of equivalent but dependent acceptor sites was introduced by Koshland et al. (1966), who noted the existence of two possible situations. (1) In positive cooperativity, ligand-induced conformational changes in the acceptor enhance subsequent ligand attachments, resulting in a sigmoidal binding response (Fig. A.5A.14A). (2) In negative cooperativity, the alternative situation occurs, with a decreased intrinsic binding constant as the result of conformational change(s) giving rise to a binding response of the same form as that reflecting heterogeneity of acceptor sites (Fig. A.5A.14B).

Allowance for nonidentity of successive intrinsic association constants is effected in the Adair (1925) formulation of the binding expression. Thus, Equation A.5A.7 for a system with $p = 2$ becomes:

$$r = \frac{2(K_{AS})_1 C_S + 2(K_{AS})_1(K_{AS})_2 C_S^2}{1+2(K_{AS})_1 C_S + (K_{AS})_1(K_{AS})_2 C_S^2}$$

Equation A.5A.39

where $(K_{AS})_1$ is the intrinsic binding constant for the interaction of S with either site on free A, and $(K_{AS})_2$ is the modified value for occupancy of the remaining site to complete saturation of the acceptor.

Multivalence of the ligand introduces the need to consider whether acceptor or ligand sites are the source of the cooperativity (Harris et al., 1995b). For systems in which the cooperativity resides in acceptor sites, the criteria used above for the interpretation of

BIBLIOTECA CENTRALE UNIVERSITY LIBRARY

binding curves for univalent ligands (Fig. A.5A.14) also apply to data for multivalent ligands provided that results are analyzed in terms of the rectangular hyperbolic relationship for an *f*-valent ligand (Equation A.5A.35) or its linear transform (Equation A.5A.34). Thus, bivalent Scatchard plots of the form shown in Figure A.5A.15, panels A and B, signify the existence of positive and negative cooperativity, respectively. However, the interpretation must be reversed when ligand sites are the source of cooperativity: the sigmoidal response (Fig. A.5A.15A) now signifies negatively cooperative binding (Harris et al., 1995b).

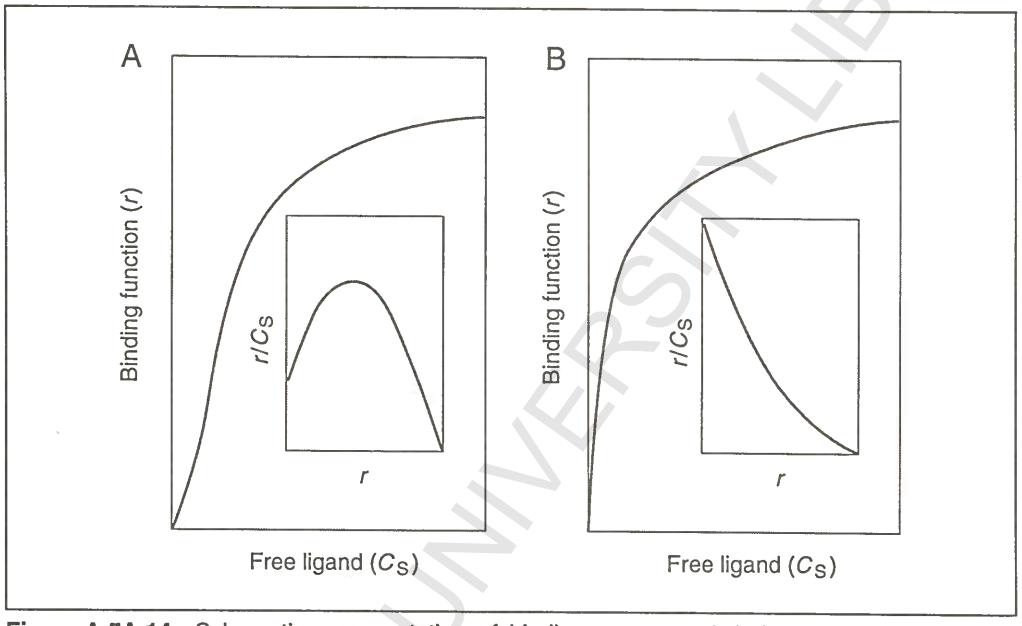

Figure A.5A.14 Schematic representation of binding curves and their Scatchard transforms reflecting **(A)** positive cooperativity and **(B)** negative cooperativity of acceptor sites for a univalent ligand.

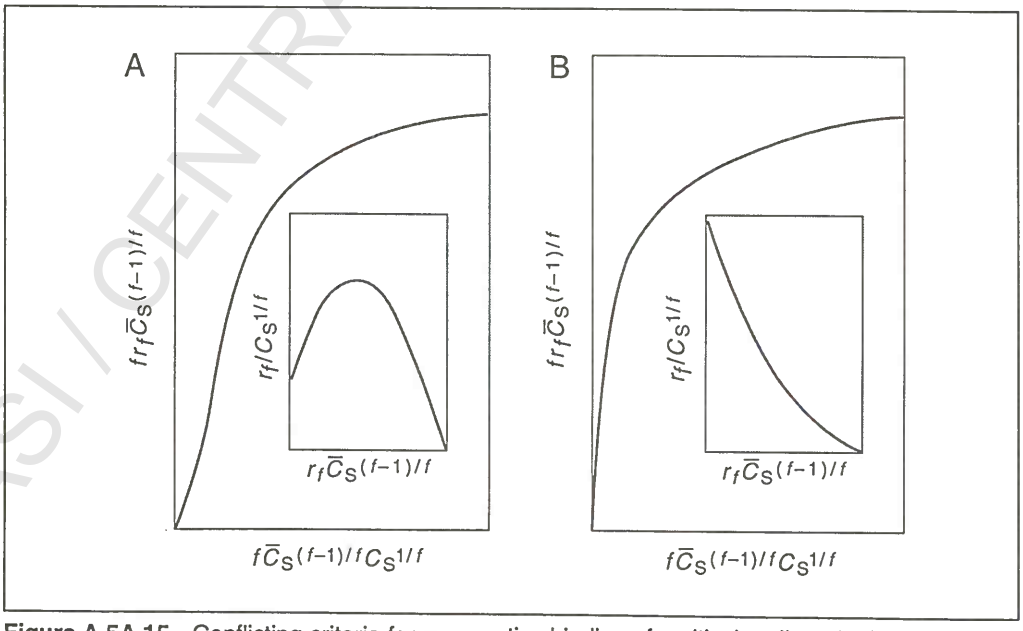

Figure A.5A.15 Conflicting criteria for cooperative binding of multivalent ligands. **(A)** Schematic binding curve and its multivalent Scatchard counterpart reflecting either positive cooperativity of acceptor sites or negative cooperativity of ligand sites. **(B)** Corresponding plots reflecting either negative cooperativity of acceptor sites or positive cooperativity of ligand sites.

ECU IASI / CENTRAL UNIVERSITY LIBRARY

Because conflicting criteria apply to the interpretation of cooperativity emanating from acceptor and ligand sites, additional information is clearly required before mechanistic significance can be ascribed to the forms of binding curves or their linear transforms. In that regard, the interpretation of results obtained for the binding of pyruvate kinase to muscle myofibrils (Harris et al., 1995b) serves to illustrate the type of approach that may be used to resolve the dilemma.

Interplays of Equilibria

Instead of considering the acceptor to undergo ligand-induced conformational changes, Monod et al. (1965) propose that a sigmoidal binding response reflects the preferential binding of a univalent ligand to one of two isomeric acceptor states that coexist in equilibrium. Although the binding sites within a given acceptor state are considered to be equivalent and independent, the intrinsic binding constant and/or the number of binding sites are allowed to differ between the two isomeric states. Even greater generality is accorded this model by allowing the preexisting equilibrium to include acceptor self-association (Nichol et al., 1967). For a system where states A and C possess p and q sites, respectively, with respective intrinsic association constants K_{AS} and K_{CS}, the binding equation becomes:

$$r = \frac{pK_{AS}C_S(1+K_{AS}C_S)^{p-1} + nXC_A^{n-1}qK_{CS}C_S(1+K_{CS}C_S)^{q-1}}{(1+K_{AS}C_S)^{p} + nXC_A^{n-1}(1+K_{CS}C_S)^{q}}$$

Equation A.5A.40

where C_A and C_C are the concentrations of the respective isomeric states, and $X = C_C/C_A{}^n$ is the equilibrium constant describing the preexisting coexistence of acceptor states (nA in equilibrium with C).

Preferential binding to an isomerizing acceptor

A major difference between the models based on acceptor isomerization and self-association is the dependence of the binding function upon acceptor concentration for $n > 1$, but its independence of acceptor concentration for the Monod et al. (1965) model ($n = 1$ in Equation A.5A.40). The latter feature is shared by the cooperativity model (Koshland et al., 1966), which is mathematically equivalent to the Monod model of allostery in the absence of a means of distinguishing between an initial state ($C_S = 0$) comprising a single acceptor state (Koshland et al., 1966) and an initial state comprising an equilibrium mixture of isomeric states with one form dominant (Monod et al., 1965).

Under favorable circumstances the molecular crowding effect of thermodynamic nonideality has potential for making such distinction (Harris and Winzor, 1988; Bergman and Winzor, 1989; Bergman et al., 1989), but pyruvate kinase is the only allosteric system to which this method has been applied, and thereby established preexistence of an isomerization equilibrium (Harris and Winzor, 1988). However, even that approach is not necessarily definitive, because failure to observe a nonideality-mediated shift towards a smaller isomeric state does not preclude the possibility that the conformation change relating to a preexisting isomerization equilibrium is too subtle for detection as a gross change in size and/or shape. Furthermore, as noted by Saroff (1991), the two models are not mutually exclusive inasmuch as coexisting acceptor states may also exhibit cooperativity of ligand binding.

In view of the above considerations, a logical approach is to set aside aspirations of an unequivocal and mechanistically correct characterization of a sigmoidal binding response

BCU MAIN CENTRAL UNIVERSITY LIBRARY

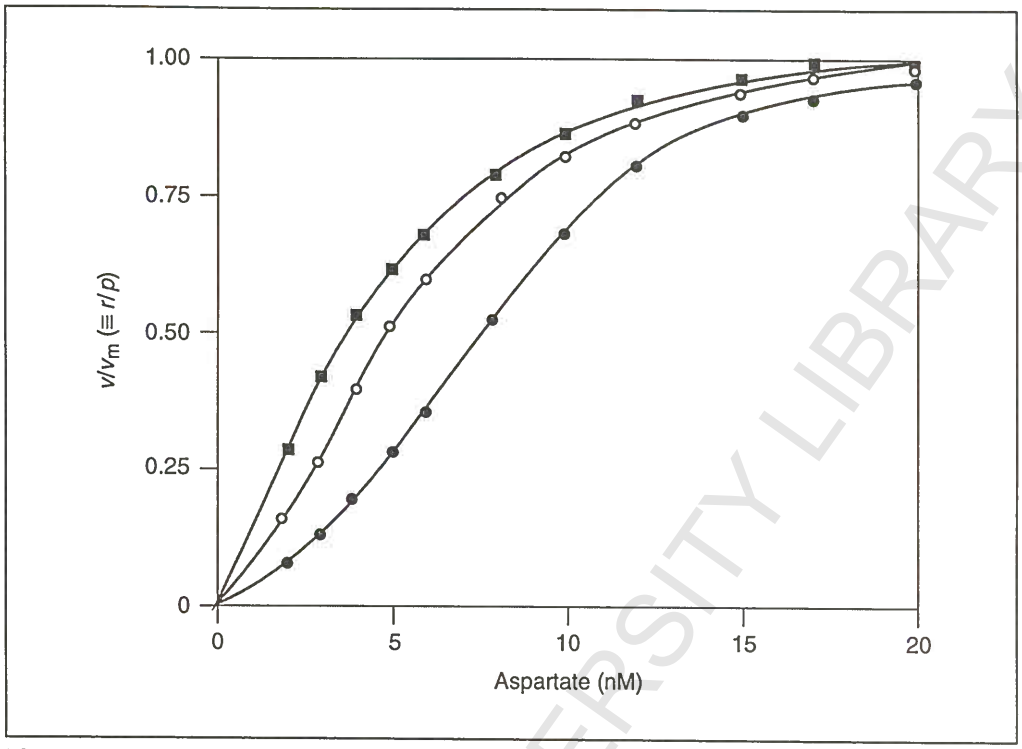

Figure A.5A.16 Allosteric activation and inhibition of *E. coli* aspartate transcarbamylase by effectors. Open circles, dependence of initial velocity v (expressed relative to maximal value v_m) upon aspartate concentration (C_S) in the presence of saturating carbamyl phosphate; filled circles and filled squares, corresponding dependences with 0.5 mM CTP and 2 mM ATP, respectively, included in the reaction mixtures. Data taken from Gerhart (1970).

in favor of an acceptable thermodynamic description in terms of the allosteric model for which parameters are evaluated more readily. The authors' inclination is towards interpretation in terms of the Monod model, which is also adapted readily to incorporate the consequences of allosteric effectors.

The moderating influence of an effector (E) binding to different sites from S on the two isomeric states is accommodated in Equation A.5A.40 with $n = 1$ by replacing the self-association constant (X) with a constitutive isomerization constant ($\overline{X}$) defined as:

$$\overline{X} = \frac{X(1+K_{CS}C_E)^z}{(1+K_{AE}C_E)^w}$$

Equation A.5A.41

where w and z are the respective numbers of sites for effector on A and C isomers, for which intrinsic binding constants of K_{AE} and K_{CE} pertain (Frieden, 1967; Changeux and Rubin, 1968; Nichol et al., 1972b). Preferential binding of E to the isomer with a lower affinity for S gives rise to allosteric inhibition and a more sigmoidal binding curve in the presence of effector. Conversely, the binding curves exhibit activation and a tendency to become rectangular hyperbolic when the effector binds preferentially to the isomer with higher affinity for S. These phenomena are evident in Figure A.5A.16, which illustrates the inhibitory effect of CTP and the activatory effect of ATP on the aspartate transcarbamylase reaction (Gerhart, 1970).

ECU IAS / CENTRAL UNIVERSITY LIBRARY

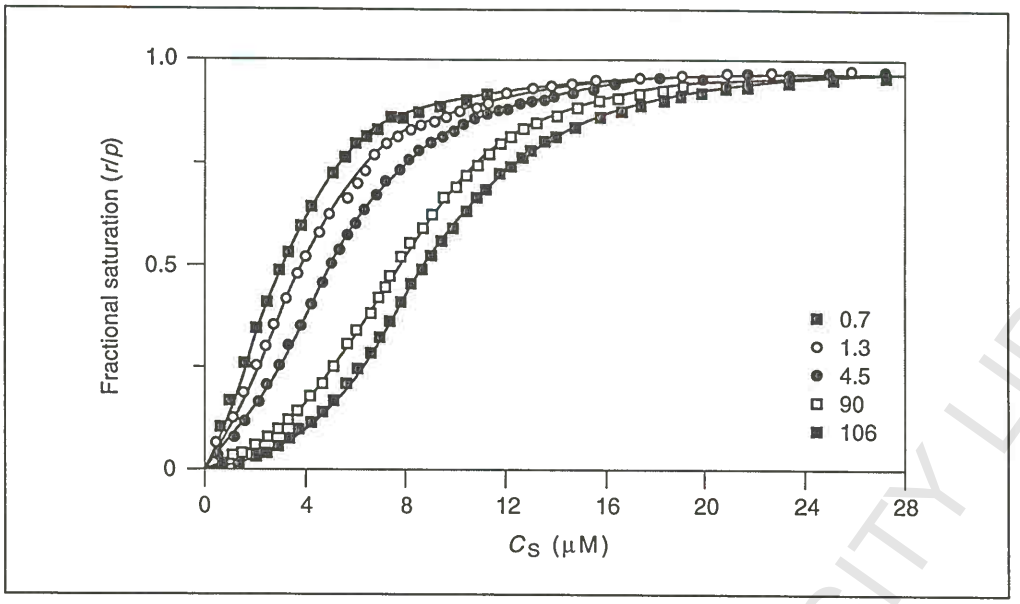

Figure A.5A.17 Concentration dependence of the binding curve for a self-associating acceptor. Binding curves for oxygen uptake by the indicated total concentrations of human hemoglobin (0.7 to 106 μg/ml) at pH 7.4. Data taken from Mills et al. (1976).

Preferential binding to a self-associating acceptor

Whereas the binding function for the interaction of a ligand with an isomerizing acceptor is expressed in terms of free ligand concentration (C_S) as the single variable, its magnitude also depends upon the free acceptor concentration (C_A), and hence the total acceptor concentration when $n > 1$ in Equation A.5A.40. In that regard, the required concentration of free monomer is given by the physically acceptable solution of the equation expressing mass conservation of acceptor, namely:

$$nX(1+K_{CS}C_S)^q C_A^n + (1+K_{AS}C_S)^p C_A - \overline{C}_A = 0$$

Equation A.5A.42

where $\overline{C}_A$ is the base-molar concentration of acceptor (total weight concentration divided by the molecular weight of monomer). Simulations of a binding curve also require the specification of magnitudes for the stoichiometry (n) and equilibrium constant (X) describing the preexisting self-association of acceptor—parameters obtained by physicochemical characterization of the acceptor in the absence of ligand (Nichol et al., 1972a; Tellam et al., 1978, 1979).

The importance of maintaining a fixed total acceptor concentration during the experimental delineation of a binding curve for a self-associating acceptor is evident from Figure A.5A.17, which summarizes the interaction of oxygen with hemoglobin over a wide range of protein concentrations (0.7 to 106 μg/ml)—a range where the tetrameric $\alpha_2\beta_2$ species coexists in equilibrium with dimer ($\alpha\beta$), which binds oxygen preferentially (Mills et al., 1976). Clearly, there is a separate binding curve for each fixed total acceptor concentration. Although a change in $\overline{C}_A$ may well enhance the accuracy with which a value of r may be determined at a given C_S, a binding curve constructed in this manner would comprise a composite of segments from the binding curves described by Equation A.5A.40 for each total concentration of acceptor used.

BCU LRC CENTRAL UNIVERSITY LIBRARY

Sigmoidal effects reflecting ligand self-association

There is a tendency to regard the acceptor as the species undergoing self-association or isomerization, and therefore to regard allostery as a property emanating from the acceptor. However, there are also situations in which the reactant undergoing self-interaction is the ligand. For the relatively simple situation in which each state of a self-associating ligand ($n\mathrm{S} \leftrightarrow \mathrm{T}$) interacts competitively with the same p equivalent and independent sites on an acceptor A for which the respective intrinsic binding constants are K_{AS} and K_{AT}, it is relevant to define the binding function as:

$$r = \left(\overline{C}_S - C_S - nC_T\right)/\overline{C}_A$$

Equation A.5A.43

whereupon the binding equation becomes

$$r = \frac{p\left(K_{AS}C_S + nK_{AT}C_T\right)}{1 + K_{AS}C_S + K_{AT}C_T}$$

Equation A.5A.44

A rectangular hyperbolic response of r upon $\overline{C}_S = C_S + nC_T$ results from ligand isomerization, whereas a sigmoidal response emanates when $n > 1$ and $K_{AS} = 0$, the situation when acceptor binds exclusively to the polymeric form of the ligand. The curves exhibit symptoms of negative cooperativity when monomeric ligand is the exclusive form of ligand bound (Nichol et al., 1969). An example of a situation in which the polymeric form of ligand binds preferentially to acceptor is provided by the interaction of chlorpromazine with tubulin (Hinman and Cann, 1976; Cann et al., 1981)—a system for which the Scatchard plot exhibits two critical points, a maximum and a minimum. Although the unusual form of the Scatchard plot was initially interpreted as signifying relatively strong interaction of chlorpromazine with a single tubulin site and weaker, positively cooperative binding of an additional eight or nine chlorpromazine molecules (Hinman and Cann, 1976), it has subsequently been shown that preferential binding of the chlorpromazine micelle ($n = 9$ to 11) is a more plausible explanation of the results (Cann et al., 1981).

Effect of Ligand Binding on Acceptor Self-Association

For an acceptor undergoing preexisting self-association between monomer and a single higher polymeric state (nA in equilibrium with C), the association equilibrium constant can be determined from studies of the acceptor in the absence of ligand. For example, the weight-average molecular weight ($\overline{M}_W$) of an equilibrium mixture with total acceptor concentration ($\overline{c}_a$ in mg/ml) is given by:

$$\overline{M}_W = \left[c_A M_A + \left(\overline{c}_a - c_A\right) n M_A\right]/\overline{c}_a$$

Equation A.5A.45

where M_A is the molecular weight of the monomer. This allows the concentration of monomeric acceptor (c_A) to be evaluated from the expression

ECU IASI / CENTRAL UNIVERSITY LIBRARY

$$c_A = \frac{\bar{c}_a(nM_A - M_w)}{(n-1)M_A}$$

Equation A.5A.46

for an assigned value of n. In fact, this specification of the association stoichiometry can be avoided by direct analysis of the sedimentation equilibrium distributions reflecting acceptor self-association (Milthorpe et al., 1975; Wills et al., 1996).

The availability of methods for determining c_A as a function of total acceptor concentration allows the association equilibrium constant X (liter^{n-1}mol^{n-1}) to be determined as:

$$X = \left[(\bar{c}_a - c_A)/c_A^n\right]\left[M_A^{n-1}/n\right]$$

Equation A.5A.47

This is frequently accomplished from a logarithmic variant of that relationship, namely

$$\log(\bar{c}_a - c_A) = \log\left(nX/M_A^{n-1}\right) + n\log c_A$$

Equation A.5A.48

which allows the magnitudes of n and X to be determined from the slope and ordinate intercept of the linear dependence of $\log(\bar{c}_a - c_A)$ upon $\log c_A$.

Provided that the ligand is sufficiently small in comparison with acceptor for the approximations $M_{AS_i} \approx M_C$ and $M_{CS_i} \approx M_C$ to apply, the perturbation by ligand of the self-association equilibrium affords quantitative information on the relative affinities of the two acceptor states for S (Nichol et al., 1972a; Baghurst and Nichol, 1975; Tellam et al., 1979). Under those circumstances the determination of molecular weight data or direct analysis of sedimentation equilibrium distributions yields $\bar{c}_A$, the weight-concentration of monomer in free and ligand-bound states, whereupon the parameter obtained from Equation A.5A.44 is a constitutive association equilibrium constant ($\bar{X}$). Its relationship to parameters within the interplay of equilibria is as follows:

$$\bar{X} = (\bar{c}_a - c_A)/c_A^n = \frac{X(1 + K_{CS}C_S)^q}{(1 + K_{AS}C_S)^{np}}$$

Equation A.5A.49

The use of this approach is illustrated by a study of the interaction between indole and α-chymotrypsin (Ford and Winzor, 1983), which undergoes reversible dimerization under the conditions of the investigation—a factor evident from the slope of 2 for the plot of sedimentation equilibrium results in the absence of ligand (Fig. A.5A.18, open symbols) according to Equation A.5A.48. Repetition of the experiments with enzyme in dialysis equilibrium with 1 mM (filled circles) and 2 mM (filled squares) indole gives rise to a progressive decrease in $\bar{X}$ that is commensurate with monomer exhibiting a five-fold greater affinity than dimeric α-chymotrypsin for ligand ($p = 1$, $q = 2$, $K_{AS} = 5K_{CS}$).

Interplays of equilibria involving acceptor self-association can be characterized with far greater certainty and precision than those involving acceptor states in isomerization equilibrium. Studies of the acceptor in the absence of ligand can usually be used to guide the distinction between preexisting and ligand-induced self-association as the source of

BCU ASTON CENTRAL UNIVERSITY LIBRARY

a sigmoidal binding curve (e.g., in Fig. A.5A.18, where the dimerization of α-chymotrypsin is clearly a preexisting equilibrium). Furthermore, perturbations of the preexisting self-association equilibrium as the result of preferential binding to one acceptor state provides additional quantitative information on the relative affinities of the two acceptor states for ligand. Indeed, measurement of the effect of free ligand concentration on the magnitude of $\overline{X}$ has formed the sole basis for characterization of the interaction between NADH (an analog of 2,3-bisphosphoglycerate) and methemoglobin—a system for which no meaningful parameters would be extracted from analysis of the binding curve (Jacobsen and Winzor, 1995). On the other hand, the characterization of an interplay of equilibria involving acceptor isomerization relies almost entirely on the analysis of the binding curve—a situation that leads to the isomerization constant, as well as the binding characteristics for the isomer with lower affinity for ligand, being curve-fitting parameters. To that end, the use of thermodynamic nonideality effected by the inclusion of molecular crowding agents to probe preexisting isomerization equilibria can, under favorable circumstances, not only detect the phenomenon but also yield an independent estimate of *X* (Harris and Winzor, 1988).

COMPLICATIONS ARISING FROM NONSPECIFIC BINDING

There are many examples in the literature where binding curves deviate from rectangular hyperbolic form as the result of elements of nonspecificity in the overall interaction between ligand and acceptor. There are two major areas where nonspecificity is encountered, and in each the term nonspecific binding has a different connotation.

ACU IASTATE CENTRAL UNIVERSITY LIBRARY

Membrane-Receptor Interactions

The binding of ligands to membrane-bound acceptors (receptors) is a fundamental phenomenon encountered in cell biology, immunology, and endocrinology. Many studies of these ligand-receptor interactions entail the use of radioactively labeled ligand to facilitate measurement of the concentration of unbound ligand in the supernatant after centrifugation to pellet the membranes. Results of such experiments rarely exhibit a rectangular hyperbolic dependence of binding upon free ligand concentration inasmuch as no plateau region is reached. Instead, there is a continuous increase in binding, which is seemingly unsaturable (filled squares, Fig. A.5A.19A). An operative criterion that is used to distinguish specific interaction from other phenomenon, termed nonspecific binding, relies upon an assertion that specifically bound ligand can be displaced by an excess of nonradioactively labeled ligand, whereas the other form of binding is unaffected by this procedure (filled circles, Fig. A.5A.19A).

The above definition of nonspecific binding only covers ligand-membrane interactions that are irreversible. In that regard, binding curves of the same form as that observed for

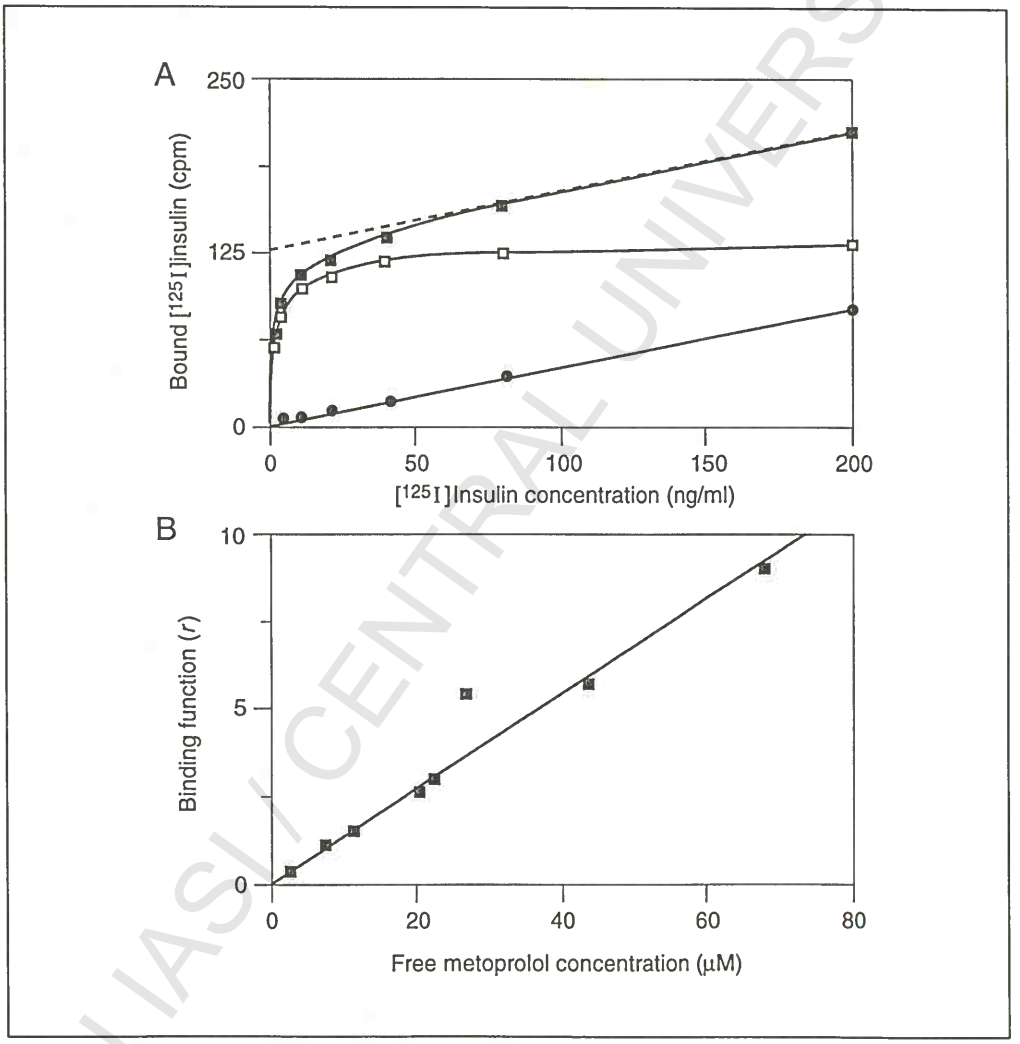

Figure A.5A.19 Nonspecific ligand interactions in studies involving membrane receptors. (**A**) Binding of [^{125}I]insulin to insulin receptors on Chinese hampster ovary cells (filled squares), and the corrected binding curve (open squares) after allowance for bound radioactivity in the presence of excess nonlabeled insulin (filled circles). RAMASWAMY H. SARMA, PH.D. IASLI / CENTRAL UNIVERSITY LIBRARY

the interaction of insulin with its membrane receptors can also reflect nonspecific uptake of ligand as the result of partition into the membrane phase. Such ligand partitioning has a similar effect on the form of the binding curve because its dependence upon free ligand concentration is also linear (Fig. A.5A.19B). However, inasmuch as the partitioned ligand can be displaced by an excess of nonradioactively labeled ligand, the phenomenon would be classified as specific binding by the above definition.

A convenient procedure for the analysis of systems exhibiting both specific binding and partition requires the collection of binding data at concentrations well in excess of those required for saturation of acceptor sites—a region where the expression for binding assumes the form

$$r\overline{C}_A = \overline{C}_S - C_S = K_p C_S + p\overline{C}_A$$

Equation A.5A.50

where multiplication of the binding function by $\overline{C}_A$ overcomes the problem that the total concentration of receptor sites is one of the parameters to be evaluated from the analysis. From Equation A.5A.50 it is evident that extrapolation of the linear part of the curve at high values of C_S to the ordinate provides the value of $p\overline{C}_A$, the concentration of bound ligand associated with saturation of receptor sites, whereas the partition coefficient (K_p) is obtained from the slope. Once the partition contribution has been defined quantitatively, it can be subtracted from the overall binding curve to allow analysis of the corrected binding curve by standard procedures. Such a procedure can thus be applied to binding curves of the form shown in Figure A.5A.19A, irrespective of the phenomenon responsible for the nonsaturable binding (Winzor and Sawyer, 1995).

Protein-Polymer Interactions

Interactions between proteins and linear polymer chains such as polynucleotides (Latt and Sober, 1967; McGhee and von Hippel, 1974) and polysaccharides (Olson et al., 1991; Munro et al., 1998) give rise to another form of nonspecificity whenever the site for ligand binding comprises a sequence of two or more consecutive residues on the polymer chain. Because of the similarity of the repeating units, there are no specific acceptor sites, as any residue sequence of the appropriate length is a potential candidate for ligand attachment. Binding curves for such systems are symptomatic of equivalent but negatively cooperative acceptor sites (Fig. A.5A.20A). However, whereas negative cooperativity is usually taken to signify an occupancy-dependent decrease in the affinity of acceptor sites, the phenomenon in protein-polymer interactions merely reflects an occupancy-dependent decrease in the concentration of free acceptor sites that exceeds the concentration of bound ligand.

For the binding of ligand to a sequence of m residues of an N-residue acceptor lattice that is governed by intrinsic association constant K_{AS}, the general form of the binding equation (Epstein, 1978) is:

$$r = \frac{\sum_{i=1}^{i=p} i^h C_i (K_{AS} C_S)^i}{1 + \sum_{i=1}^{i=p} i^h C_i (K_{AS} C_S)^i}$$

Equation A.5A.51

ECU IASTCENTRAL UNIVERSITY LIBRARY

where p is the integer value of N/m, and ${}^{h}C_{i}$ is the number of possible arrangements of the h items (bound ligands and unoccupied lattice residues) available for distribution on the lattice (Latt and Sober, 1967). The latter is given by:

$$ {}^{h}C_{i} = (N - mi + 1)!/[i!(N - mi)!] $$

Equation A.5A.52

This combinatorial approach for derivation of the binding equation becomes progressively more cumbersome with increasing length of the acceptor lattice. Furthermore, the need to specify N precludes its use, for example, with DNA as the linear polymer chain because

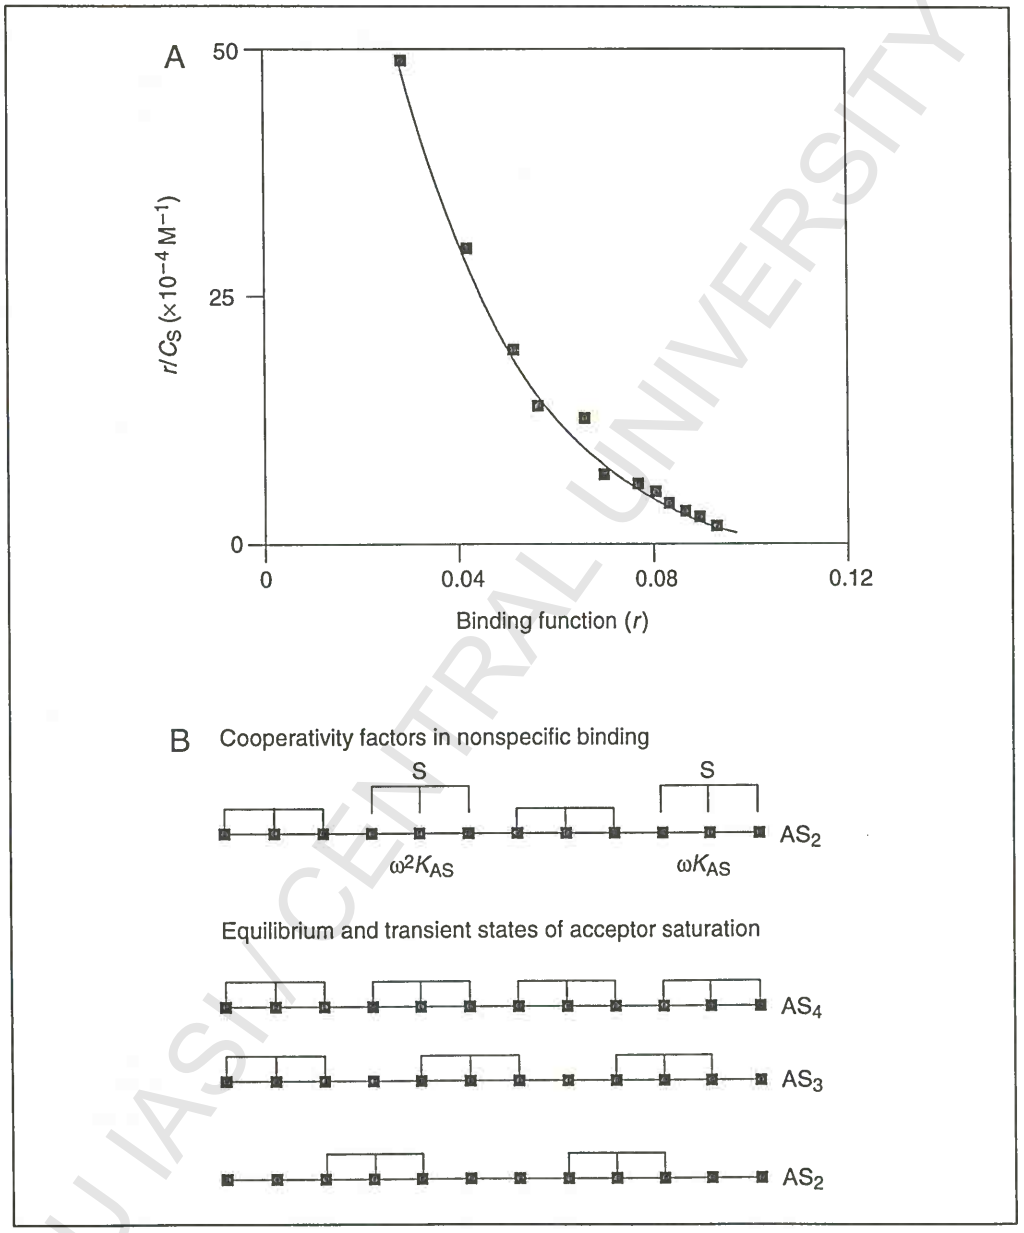

Figure A.5A.20 Effects of nonspecificity in the binding of ligands to a sequence of residues on a linear polymer chain. (**A**) Scatchard plot of experimental results (Latt and Sober, 1967) for the interaction of an ε-dinitrophenyl-labeled hexameric lysine oligopeptide with poly(I + C). (**B**) Schematic representation of thermodynamic and kinetic aspects of nonspecific interaction between a ligand and three-residue sequences on a twelve-residue linear polymer.

RAU IASI / CENTRAL UNIVERSITY LIBRARY

the number of nucleotides comprising the chain is frequently unknown and almost certainly variable as the result of heterogeneity with respect to polynucleotide chain length. These difficulties may be overcome by switching to a probability approach, which only requires N to be a fairly large number. For the random binding of ligand to m-residue sequences of an infinite lattice, the Scatchard transform of the binding equation (McGhee and von Hippel, 1974) is:

$$r/C_S = K_{AS}(1-mr)\left(\frac{1-mr}{1-(m-1)r}\right)^{m-1}$$

Equation A.5A.53

which also has the advantage of being a closed solution.

Conventional cooperativity is incorporated into the model by designating the modified affinity of a sequence adjacent to a bound ligand as ωK_{AS}, the product of the usual intrinsic binding constant and a dimensionless factor ω, and designating that for a flanked sequence as $\omega^2 K_{AS}$ (Fig. A.5A.20B). The Scatchard formulation of the probability treatment of nonspecific binding (McGhee and von Hippel, 1974) then becomes:

$$r/C_S = \frac{K_{AS}(1-mr)\left[(2\omega+1)(1-mr)+r-R\right]^{m-1}\left[1-(m+1)r+R\right]^2}{\left[2(\omega-1)(1-mr)\right]^{m-1}\left[2(1-mr)\right]^2}$$

Equation A.5A.54

where the term R is presented separately for simplification of the typestting of Equation A.5.54.

$$R = \left\{\left[1-(m+1)r\right]^2 + 4\omega r(1-mr)\right\}^{1/2}$$

Equation A.5A.55

Values of ω greater and less than unity signify classical positive and negative cooperativity, respectively. The application of Equation A.5A.54 is addressed in depth by Kowalczykowski et al. (1986).

Finally, it should be noted that there is a kinetic consideration that may affect the attainment of equilibrium in the binding of ligand to a sequence of acceptor residues—a factor evident from the lower part of Figure A.5A.20B for the binding of ligand to three-residue sequences on a twelve-unit lattice. Clearly, the maximum number of ligands that can attach to the chain is four, but random binding can lead to situations in which the lattice is effectively saturated with only three and even two ligand molecules attached (Fig. A.5A.20B). From the thermodynamic viewpoint, these latter situations are not viable options because they merely represent transient states en route to the equilibrium state of four ligand molecules bound at chain saturation. However, although the time-course of equilibrium attainment is irrelevant to the thermodynamics of nonspecific ligand binding, the experimenter must ensure that sufficient time be allowed for the kinetics of bound ligand rearrangement to take its course before the equilibrium measurements are made for substitution into Equations A.5A.51-A.5A.55 (Epstein, 1979; Munro et al., 1998). In that regard, the kinetic problem is maximal for high levels of acceptor saturation, and therefore impinges on the evaluation of m, the sequence length to which ligand binds. Indeed, because this parameter is often deduced under conditions where the acceptor-li-

SCU IASRI CENTRAL UNIVERSITY LIBRARY

gand interaction is stoichiometric, the endpoint of the titration reflects irreversible rather than equilibrium binding. In such titrations there is effectively no opportunity for the dissociation that is necessary to relocate bound ligate molecules and hence achieve maximal efficiency of site occupancy—the requirement for the equilibrium situation. An algorithm is now available for determining the equilibrium endpoint from the measured, irreversible endpoint of a stoichiometric titration (Munro et al., 1998).

CONCLUDING REMARKS

In seeking to explain the behavior of plants and animals at a molecular level, biochemists usually adopt a simple reductionist approach and proceed towards an understanding of in vivo complexity. This transition involves a definition of the in vivo state and eventually the matching of in vitro conditions with those existing in biological tissues or fluids. Since specific recognition mechanisms and binding affinities control the biochemical dynamics of living systems, the thermodynamic binding parameters determined under in vitro conditions must be matched to those pertaining to living systems. The acquisition and quantitative analysis of binding data is therefore an essential part of this process.

Nature has evolved a variety of complex mechanisms to deal with the interleaving and interdependence of biochemical reactions. While the simple binding function (Equation A.5A.9) remains the starting point for all quantitative analyses of these processes, it is rare that it provides the complete picture. Site heterogeneity, ligand multivalence, ligand and acceptor self-association or isomerization, and the binding of ligands to linear arrays of sites are just a few of the deviations from simple binding behavior that have been discussed in this unit. A common thread in this discussion is the matching of a binding model to experimental results. It has not been the authors' intention to provide an exhaustive list of the variety of models that have so far been examined in the literature, but rather to illustrate an approach that involves the formulation of a model-dependent binding function and a testing of the experimental data against the derived equations.

MAIN INDEX

How to Use This Index

A new main index is provided once a year. Thereafter, with the next three supplements, a cumulative supplement index, which amends the main index, will be provided. Thus, readers should consult both the main index and the supplement index when seeking an entry, as page numbers may change for replacement units and new entries will be added.

A

AAA, *see* Amino acid analysis
AAA (*Anguilla anguilla*), as lectin source, 9.1.3 (table)
Abscissa intercept, in ligand-binding theory, A.5A.21–A.5A.22
Absorbance
  in concentration determination
    at A_{205}, 3.1.2, 3.1.4–3.1.6
    at A_{280}, 3.1.1–3.1.2, 3.1.4–3.1.6
    absorption maxima and molar absorptivity of amino acids, 3.1.4–3.1.5
    concentration limits of interfering reagents, 3.1.6 (table)
    conversion equations, 3.1.6
    pH and polarity in, 3.1.5
  of recombinant proteins, 6.1.2, 6.2.8, 7.1.3, 7.1.5, 7.1.6 (table)

Acceptor saturation, in ligand-binding theory, A.5A.8, A.5A.10, A.5A.36
Acceptor sites, in ligand-binding responses
  characterized, A.5A.1–A.5A.4
  heterogeneity, A.5A.21–A.5A.23
  and immobilized affinity sites, interaction, A.5A.17–A.5A.18 (fig.)
  independent but nonequivalent, A.5A.22
Accessibility assays, of recombinant proteins, 7.1.4 (table)
Acetate
  in chromatofocusing, 8.5.3
  production, in *E. coli* fermentation, 5.3.17 (fig.)
Acetic acid, in
  nondenaturing polyacrylamide gels, 10.3.2 (table)
  recombinant protein extraction, 6.1.13
  RP-HPLC, 6.5.9
Acetone, in hydrophobic-interaction chromatography, 8.4.9
Acetone precipitation, in concentration of proteins, 4.5.13–4.5.14, 4.5.29, 12.3.6–12.3.7
Acetonitrile, in RP-HPLC, 6.5.9
Acetylation, in labeling using anhydride, 3.3.2 (fig.), 3.3.11–3.3.12
Acetyl blocking groups, removal of
  by acid hydrolysis, 11.7.9, 11.7.13
  with trifluoroacetic acid, 11.7.10
N-Acetyl-D-galactosamine (GalNAc)
  cleavage of, 12.4.12, 12.4.14
  defined, 12.1.6
β-*N*-Acetyl-D-glucosaminidase, 4.3.15
O-Acetyl-D-galactosamine-linked glycoproteins, monosaccharide distribution and modification in, 12.2.11 (table)
N-Acetyl-D-glucosamine (GlcNAc)
  defined, 12.1.6
  in lectin affinity chromatography, 9.1.7–9.1.8
  monosaccharide distribution and modifications in, 12.2.11 (table)
N-Acetyl-glucosamine-pyrophosphate dolichol (GlcNAc-PP-dolichol), 12.3.8
N-Acetylglucosaminyltransferase (GlcNAc-transferase), 12.3.2 (table), 12.3.3 (fig.), 12.3.8
N-Acetyl-D-neuraminic acid (Neu5Ac), defined, 12.1.7
N-Acetylphenyl ethyl ester, UV absorption spectra, 7.2.1 (fig.)
N-Acetyl-L-tryptophanamide, UV absorption spectra, 7.2.1 (fig.)
N-Acetyl-L-tyrosineamide, UV absorption spectra, 7.2.1 (fig.)
Acid blob domain
  expression cassette containing, 19.2.36
  protein fusions to, 19.2.1
Acid digestion–ninhydrin assay
  applications, 3.4.20
  interfering compounds, 3.4.18 (table)
  method, 3.4.7–3.4.8
  sample size and detection range, 3.4.22 (table)
  TCA precipitation of samples, 3.4.13
Acid hydrolysis
  of phosphoamino acids, 13.1.2, 13.3.1–13.3.2, 13.3.7
  in quantitative amino acid analysis, 3.2.2
  See also Acid digestion–ninhydrin assay
Acid phosphatases
  in phosphorylation detection, 13.5.2–13.5.3, 13.5.6, 13.5.7
  in *S. cerevisiae* expression system, 5.6.2, 5.6.4 (fig.), 5.6.5, 5.6.6
Acid precipitation, of recombinant interleukin1β, 6.2.12
Acidic amphoteric buffers, for CZE
  characterized, 10.13.1–10.13.6
  used in protein separation, 10.13.7–10.13.9
  See also Isoelectric buffers
Acids and bases, concentrated, storage, A.2A.3
Acrylamide
  alkylation of cysteine residues using, 15.1.2 (table), 15.1.9
  in nondenaturing electrophoresis
    for acetic acid gels, 10.3.2 (table)
    concentration and molecular weight standard curves, 10.3.5–10.3.7, 10.3.8 (fig.), 10.3.9
    for glycine gels, 10.3.5 (table)
    for phosphate gels, 10.3.3 (table)
    for Tris gels, 10.3.4 (table)
  in SDS-PAGE
    continuous, for separating gels, 10.1.13 (table)
    heavy, for gradient gels, 10.1.19 (table), 10.1.23 (table)
    light, for gradient gels, 10.1.19 (table), 10.1.22 (table)
    for modified Laemmli peptide separation gels, 10.1.12 (table)
    multiple single-concentration gels, 10.1.16 (table)
    for separating and stacking gels, 10.1.5 (table)
    for tricine peptide separation gels, 10.1.10 (table)

coupling peptides to carrier protein, 18.3.8–18.3.9, 18.3.12–18.3.13, 18.3.15–18.3.16
designing multiple antigenic peptide, 18.3.7–18.3.8, 18.3.16
designing peptide for coupling to carrier protein, 18.3.5–18.3.7
free sulfhydryl assay, 18.3.9–18.3.11
manual inspection for sequence selection, 18.3.4, 18.3.5 (table), 18.3.15
reducing cysteine groups, 18.3.11–18.3.12
strategy, 18.3.1–18.3.2
structural features in, 18.3.14–18.3.15
uses of, 13.6.1, 13.6.10–13.6.11
yield of, 13.6.12
Antibody-Sepharose (Ab-Sepharose)
preparation of, 9.5.6–9.5.7
use in
batch purification, 9.5.5
column purification, 9.5.1–9.5.4
Anti-CRD antibody, 12.5.7, 12.5.11, 12.5.12
Antigenic sites, hydropathy profiles in predicting, 2.2.5–2.2.7
Antigens
detection by immunoblotting, UNIT 10.10
formation in murine cells, 5.9.9

POST ASU CENTER FOR UNIVERSITY LIBRARY

isolation of soluble or membrane-bound, by immunoaffinity chromatography, 9.5.1–9.5.4, 9.5.9
Antimicrobial agents, for ion-exchange media storage, 8.2.25
Anti-phosphopeptide antibodies, *see* Antibodies, anti-phosphopeptide
Anti-phosphotyrosine antibodies, immunoblotting and detection, 13.4.1–13.4.2, 13.4.4–13.4.5
Antithrombin III (At-III), 5.6.3–5.6.6
α-1-Antitrypsin, 6.4.2
AOX genes, 5.7.3–5.7.11
Apical plasma membranes, 4.2.34, 4.2.48
arg5 genotype, 5.7.3 (table), 5.7.4
Argos hydropathy scale, 2.2.3
Aromatic amino acids
as chromophores in fluorescence, 7.7.1, 7.7.11–7.7.13
in spectrophotometric determination of protein concentration
absorbance, 3.1.1–3.1.2, 3.1.4–3.1.6
fluorescence emission, 3.1.3, 3.1.4–3.1.5
in UV absorption spectroscopy, UNIT 7.2
Aryl ligand, in hydrophobic-interaction chromatography, 8.4.3
Aseptic technique, *see* Sterile technique
Asp, *see* Aspartic acid
aspA transcription terminator, 6.7.1
Asparagine–glycine bonds (Asn-Gly), cleavage with hydroxylamine
on membranes, 11.5.5–11.5.6
in solution, 11.4.4, 11.4.7 (table)
Aspartic acid (Asp), for capillary electrophoresis
for β-casein, with HEC, 10.13.8 (fig.)
characterized, 10.13.1–10.13.2
cleavage of recombinant proteins at, 7.1.10
conductivity and pH profiles
urea, 10.13.4 (fig.)
urea with HEC, 10.13.5 (fig.)
water, 10.13.3 (fig.)
for gliadin, with HEC
from bread wheat flour, 10.13.11 (fig.)
from durum wheat flour, 10.13.10 (fig.)
Aspartic acid–proline bonds (Asp-Pro), cleavage with formic acid
on membranes, 11.5.5, 11.5.6
in solution, 11.4.4, 11.4.7 (table)
Asp-N endoproteinase, *see* Endoproteinase Asp-N
Assays, general considerations
comparison of methods, 1.1.3
in fractionation evaluation, 4.1.7–4.1.8
kinetic, UNIT 3.5
laboratory equipment required, 1.1.5
for membrane-bound proteins, 1.2.3
mobility-shift, 9.7.6–9.7.9
protease activity in stock solutions, 11.1.8–11.1.9, 11.1.13
protein purity, structural and functional assessment, 8.1.2–8.1.3
quantitative amino acid analysis in, 3.2.1
Association rate constant k_{assoc}, 19.1.3–19.1.4
ASTRA software, 7.8.6
Asymmetric membrane disks, 4.4.4–4.4.6
Asymmetry, optical, relation to circular dichroism, 7.6.1
Asymmetry factor, in hydrophobic-interaction chromatography, 8.4.9 (fig.), 8.4.10
At-III (human antithrombin III), 5.6.3–5.6.6
ATM gene, coding sequence, 2.5.11–2.5.12
ATP
alkaline phosphatase hydrolysis of, 13.5.6–13.5.7
in endosome fusion, 4.3.16
^{32}P-labeled
in direct analysis of kinases, 13.8.10
for enzymatic phosphorylation/permeabilization studies, 13.8.1–13.8.5, 13.8.8, 13.8.18–13.8.19, 19.3.1
specific radioactivity determination, 13.8.11–13.8.15
ATPase, 17.1.43
AtT-20/D16V mouse pituitary cells, 4.2.18–4.2.19
Australian National University Molecular Biology Resources, 2.1.14, 2.1.15 (table)
Autoclaving of biohazardous waste, A.2A.2
Autographa californica, *see* Baculovirus expression system
Autoradiography
exposure procedures
direct, 10.11.2–10.11.3
fluorographic, 10.11.3–10.11.4
intensifying-screen, 10.11.4
sensitivity of X-Omat AR film, 10.11.4 (table)
for specific applications, 10.11.3 (table)
TranScreen intensifying screen, 10.11.4–10.11.5
film
handling of, 10.11.2
preflashing of, 10.11.5
types of, 10.11.1–10.11.2
processing
automated, 10.11.5
manual, 10.11.5–10.11.6
quantitative, 10.11.2
Available capacity
defined, 8.2.8
determination of, 8.2.19
Avidin, 3.6.10, 3.6.11, 3.6.12
Avidin-biotin, immunoprobing with, 10.10.3–10.10.4
Azide
detection, A.2A.22–A.2A.23
disposal, A.2A.21–A.2A.22

B

Baby hamster kidney 21 (BHK-21) cells
carboxylation of factor VIII in, 5.9.10
glycosylation in, 5.9.10
for recombinant protein expression, 5.9.3 (table), 5.9.4, 5.9.13
Bacillus subtilis, in recombinant protein production, 1.2.4
Bacteria
endotoxins and lipopolysaccharides, detection and elimination, 7.1.2
fermentor for, 5.3.3 (fig.)
thermostable proteins, 1.2.3–1.2.4
See also specific species
Bacterial colonies, growth in media
isolating single colonies
by spreading a plate, A.4B.2
by streaking a plate, A.4B.2
isolating and titering bacterial colonies by serial dilutions, A.4B.2
larger cultures, A.4B.1
monitoring, A.4B.1
overnight cultures, A.4B.1
replica plating, A.4B.3
strain storage and revival, A.4B.3
Bacteriophage
λ, in thioredoxin gene fusion expression vectors, 6.7.2
libraries
cDNA expression, screening of, 19.3.5
λ-derived, for protein identification, UNIT 19.3
protein expression
for biosynthesis of polypeptides, 18.4.8
for phage-based expression cloning, 19.3.1–19.3.2
Bacteriophage lambda, *see* pL
Bacteriorhodopsin, hydopathy profile, 2.2.9–2.2.10, 2.2.11 (fig.)
Bait protein
characterizing, 19.2.3–19.2.11
used in expression cloning, UNIT 19.3
immunoblot analysis, for fusion protein, 19.2.10
interactor hunts with, multiple simultaneous, using interaction mating, 19.2.23
plasmid pEG202 for expressing, 19.2.1
testing, 19.2.37
toxic
alternate hunt with interaction mating, 19.2.23
reducing exposure of yeast to, 19.2.35
Basic Local Alignment Search Tool, *see* BLAST
Batch adsorption
vs column purification, 8.2.3–8.2.4
ion-exchange media for, 8.2.4 (table)
and step-gradient elution, ion-exchange chromatography, 8.2.10–8.2.13
Batch culture, of mammalian cells
cell cycle and protein production, 5.9.12
proteolysis and glycosidase activity, 5.9.12
quantity of protein produced by, 5.9.13 (table)
Batch purification method, 9.7.2–9.7.4
Baculovirus expression system
advantages of, 5.4.1
cell growth and viability determination, 5.5.13
life cycle, 5.4.1, 5.4.2 (fig.)
polyhedrin protein, 5.4.1–5.4.2
post-translational modification in insect cells, 5.4.3
production
antibiotics in, 5.5.16–5.5.17
in bioreactors, 5.5.5–5.5.6, 5.5.14–5.5.15, 5.5.16
contamination, 5.5.16
culture media nutrient monitoring, 5.5.12–5.5.13
harvesting, 5.5.11, 5.5.17
insect cell line choice and maintenance, 5.5.15
kinetics of expression, 5.5.4–5.5.5, 5.5.15–5.5.16
large-scale, 5.5.2–5.5.3, 5.5.14–5.5.15
media, 5.5.16
in perfusion, 5.5.5–5.5.6, 5.5.15
protein analysis sample preparation, 5.5.12
strategy, 5.4.2–5.4.3
titrating with end-point assay, 5.5.10, 5.5.15
titrating with plaque assay, 5.5.8–5.5.9, 5.5.15
viral stock preparation, 5.5.15
Base hydrolysis, of radiolabeled proteins, 12.5.8–12.5.9, 12.5.12
Basic Local Alignment and Search Tool, *see* BLAST family of programs
Basolateral plasma membranes, 4.2.34
Batch adsorption
of antigens, 9.5.5

IUPUI CENTRAL UNIVERSITY LIBRARY

in capture stage of purification, 8.1.3–8.1.4
using hydroxylapatite, 8.6.6–8.6.7, 8.6.10
Batch fermentation, of *E. coli*, 5.3.1–5.3.8, 5.3.14–5.3.16
Bayer's patches, 5.1.4
BCA assay, *see* Bicinchinonic acid assay
BCIP, *see* 5-bromo-4-chloro-3-indolyl phosphate
Bead diameter
and column purification, 8.2.4–8.2.7 (table)
in chromatography, 8.1.4
Beckman
centrifuges, A.2C.1, A.2C.4–A.2C.5 (table)
ultracentrifuges, 6.1.18
Bed compression, GF chromatography, 8.3.28
Benzidine
decontamination, of aqueous solutions, A.2A.10
detection of, A.2A.10
disposal, A.2A.7–A.2A.9
spills, A.2A.9
Benzoquinone, in activating matrix hydroxyl function, 9.3.2 (table)
β-galactosidase, *see* under G
β-sheet motifs, 17.1.18–17.1.19
β strands
characteristics, 2.3.11 (table)
Chou and Fasman prediction rules, 2.3.11 (table)
conformational preference parameters and assignments, 2.3.3–2.3.5
in hemoglobin, interleukin, and profilin, 2.3.4 (fig.), 2.3.12–2.3.14, 2.3.18 (fig.)
BHK-21 cells
growth and preparation, 4.3.10
HRPO internalization, 4.3.1–4.3.3
VSV G protein internalization, 4.3.3–4.3.5
see also Baby hamster kidney 21 cells
Bibliographies, molecular biology resources, 2.1.15 (table)
Bicinchinonic acid (BCA) assay
calibration plots, 3.4.6, 3.4.17 (table)
gel dialysis of samples, 3.4.12–3.4.13
interfering compounds, 3.4.17–3.4.18, 3.4.19
method, 3.4.5–3.4.6
reactions in, 3.4.17 (fig.)
sample size and detection range, 3.4.22 (table)
TCA precipitation in, 3.4.13, 3.4.19–3.4.20
variability in, 3.4.21–3.4.22
Bimolecular interaction analysis, of recombinant proteins, 7.1.5 (table)
Binding, *see* Ligand binding
Binding pH, for ion-exchange chromatography, 8.2.1 (fig.), 8.2.16–8.2.18
Binding proteins, classification, 1.2.2 (table)
Bioassays, disadvantages of, 1.1.3
Bio-Beads, for hydrophobic-interaction chromatography, 8.4.2 (table)
Bio-Gels, 6.3.11
Biohazards
disinfectants for, A.2A.2
disposal, A.2A.2
precautions, A.2A.1–A.2A.2
Bioinformatics, UNIT 2.4
Bioligands
affinity purification of
activation and coupling methods, 9.3.1–9.3.2
CNBr activation, 9.3.2, 9.3.4–9.3.5, 9.3.11–9.3.13
ligand choice, 9.3.10
matrix selection, 9.3.1 (fig.), 9.3.3 (table), 9.3.8–9.3.9
p-nitrophenyl chloroformate activation, 9.3.5–9.3.6, 9.3.11
reagents activating hydroxylic matrices, 9.3.2 (table), 9.3.10–9.3.11
spacers, 9.3.10, 9.3.11 (fig.)
synthetic matrices, 9.3.11
tresyl chloride activation, 9.3.6–9.3.7, 9.3.11, 9.3.12 (fig.)

for hen egg white lysozyme, 7.6.8 (fig.)
for proteins with high helix concentration, 7.6.7 (fig.)
for CSA, 7.6.8 (fig.)
interpretation of, 7.6.15–7.6.19, 7.6.21–7.6.22
parameters for scanning, 7.6.11 (table), 7.6.13 (fig.)
recording, 7.6.10–7.6.15
spectrometer
calibration of, 7.6.8
characteristics of, 7.6.7
cells for, 7.6.8–7.6.9
units for, 7.6.3
cI repressor gene, 5.1.2
cI repressor protein, in thioredoxin expression system, 6.7.2–6.7.3
cis Golgi stack, in mammalian cells, 5.9.10
cis-trans isomerization, 6.4.1, 6.4.6
CL100, 13.1.3
^{14}C labeling
applications, 3.3.16–3.3.17
at cysteine residues using iodoacetic acid oriodoacetamide, 3.3.13
at lysine or N-terminus by acetylation using anhydride, 3.3.11–3.3.12
at lysine or N-terminus by reductive alkylation, 3.3.12
in N-linked glycosylation, 12.3.5
during peptide synthesis, 3.3.14–3.3.15
strategies, 3.3.1 (table)
Clarification of protein samples, 4.5.2, 4.5.3 (fig.)
Classification of proteins, by
function, 1.2.1, 1.2.2 (table)
size, 1.2.1
structural characteristics, 1.2.1
Clathrin-coated vesicles
density shift using gold conjugates, 4.2.48
purification, 4.2.47
Cleavage, *see* Chemical cleavage *and* Enzymatic digestion
Cloning
expression, UNIT 19.3
single-cell, 5.10.9–5.10.10
sites, in pEG202, 19.2.35
See also Baculovirus expression systems, *Escherichia coli* expression systems, *and* Recombinant proteins
Clostripain, in enzymatic digestion on PVDF membranes, 11.2.2 (table), 11.2.5
Cluster methods in sequence analysis, 2.1.10, 2.1.11 (fig.)
CMV promoter, *see* Cytomegalovirus promoter
4CN, *see* 4-Chloro-1-naphthol
CNBr, *see* Cyanogen bromide
Coated pits, density shift using colloidal gold conjugates, 4.2.40
Coding sequence (CDS), for peptide sequence databases, 2.5.3
Cohn fractionation, 1.1.1, 4.5.13, 4.5.29
Colicins, 17.1.40
Collagenase, in fusion protein cleavage, 5.1.6
Collision-induced dissociation fragment ions, low-energy, 16.3.1
Colloidal gold conjugates, in density shift centrifugation
applications, 4.2.48–4.2.49
merits and limitations, 4.2.6–4.2.7
method, 4.2.37–4.2.42
requirements, 4.2.51
Colorimetric methods
for pyroglutamate aminopeptidase activity, 11.7.4–11.7.5
for quantitation of free sulfhydryls, 15.1.13
total protein assays, UNIT 3.4
Colorimetric microkjeldahl nitrogen, calibration plots, 3.4.17 (table)
Column chromatography
vs batch adsorption techniques, 8.2.3–8.2.4
in capillary zone electrophoresis, UNIT 10.13
chromatogram of typical results, 8.2.29 (fig.)
ion-exchange media for, 8.2.5–8.2.7 (table)
in ligand-binding theory, APPENDIX 5A
with linear gradient elution, 8.2.13–8.2.16
for recombinant protein characterization, UNIT 7.10
scale-up calculations for, 8.2.9 (table), 8.2.10
See also Capacity; Ion-exchange chromatography
Columns
in bacterial expression of polypeptides, 18.4.14
calibration, for molecular size determination, 8.3.19–8.3.21
in capillary electrophoresis (CE), 10.9.1, 10.9.2
in capillary zone electrophoresis (CZE)
performance evaluation, standard protein mix for, 7.10.7 (fig.)
plugging, 10.13.15
prepacked, characterized, 7.10.2 (table)
selection by fractionation range, 7.10.2, 7.10.7
selection by type and size, 7.10.1, 7.10.3
for size-exclusion fractionation of recombinant proteins, 7.10.1–7.10.7
in ligand binding theory
chromatographic variants, A.5A.17
in chromatofocusing
packing, 8.5.5–8.5.6
regenerating, 8.5.7
in gel-filtration chromatography
general instructions, 8.3.8–8.3.10
for inclusion body extraction, 6.3.11
for molecular size determination, 8.3.17–8.3.18
for protein fractionation, 8.3.14–8.3.15
of recombinant proteins, 6.2.9, 6.2.13, 6.3.4–6.3.5, 6.5.5
in hydroxylapatite chromatography, 8.6.1
in immunoaffinity chromatography, 9.5.1–9.5.4, 9.5.2 (fig.)
in ion-exchange chromatography
preparation of, 8.2.15
regeneration of, 8.2.15–8.2.16
required in laboratory, 1.1.5
See also Capacity; Ion-exchange chromatography
Compact domains, 2.3.1
Comparative homology modeling, 2.3.3
COMPARE (software), 2.1.3
Competitive binding assays, for ligand-binding theory, illustrative analysis, A.5A.15–A.5A.20
Complete minimal dropout medium, for yeast growth (recipes)
powder and liquid medium, A.4L.2
plates, A.4L.3
Complexed acceptor, measurement for ligand-binding theory, illustrative analysis, A.5A.11–A.5A.15
Complexed ligand, measurement for ligand-binding theory, illustrative analysis, A.5A.11–A.5A.15
Computational analysis
using BLAST programs, UNIT 2.5
methods for protein sequence analysis, UNIT 2.1
Computer-assisted selection of antigenic peptide sequences, 18.3.2–18.3.4, 18.3.15
Computer software, *see* Software
Concanavalin A (Con A)
in glycoprotein purification, 9.1.2 (table)
Sepharose affinity chromatography, 9.1.4–9.1.6
Concentration determination
at A_{205}, 3.1.2, 3.1.4–3.1.6
at A_{280}, 3.1.1–3.1.2, 3.1.4–3.1.6
fluorescence emission, 3.1.3, 3.1.4–3.1.5
total, in ligand-binding theory, A.5A.2–A.5A.4 (fig.), A.5A.31
Concentration methods
acetone precipitation, 12.3.6–12.3.7
dialysis through regenerated cellulose tubing, 4.4.1–4.4.4
for protein samples, 4.5.2–4.5.3
for recombinant proteins
equipment, 6.1.19
HIV-1 integrase, 6.5.12
interleukin 1β, 6.2.8, 6.2.9
precipitation, 5.2.12, 5.2.15
for soluble proteins, 1.3.4–1.3.5
ultrafiltration
with centrifugal ultrafilters, 4.4.8–4.4.9
membrane selection and characteristics, 4.4.9–4.4.12
tangential-flow, 4.4.6–4.4.8
through asymmetric membrane disks, 4.4.4–4.4.6
Concentration polarization, 4.4.11
Conductivity
in capillary electrophoresis for peptide/protein separation
characterized, 10.13.2
profiles for specific buffers, 10.13.3–10.13.5 (figs.)
measurement, 4.4.3
Conformational changes and switches, analysis by electronmicroscopy, 17.2.10–17.2.11
Conformation of recombinant proteins, 7.1.3–7.1.8
Conformers, defined, 12.1.4–12.1.5
Consensus sequence, 2.1.10
Constitutive route in translocation, 5.9.7–5.9.9
Contact blots, protein detection in polyacrylamide gels, 10.6.2–10.6.3, 10.6.6–10.6.8
Contaminants
in assessment of protein purity, 8.1.2

BOULDER / CENTRAL UNIVERSITY LIBRARY

in hydrophobic-interaction chromatography, 8.4.13–8.5.14
in ion-exchange media, removal, 8.2.24
protein, 11.10.7–11.10.8
in recombinant expression systems, 6.1.17
Continuation in sequence analysis, 2.1.1
Continuous electrophoresis
nondenaturing, 10.3.1–10.3.5, 10.3.9–10.3.10
SDS-PAGE, 10.1.13–10.1.14, 10.1.33
Continuous gradients
in differential centrifugation by equilibrium, 4.2.9–4.2.10
in gradient fractionation using nonionic iodinated solutes, 4.2.21
in rate zonal centrifugation using sucrose, 4.2.13
Coomassie blue
brilliant blue-G, contaminants in, 11.2.6
in digital electrophoresis analysis, 10.12.5, 10.12.10
dye–binding assay
applications and reliability, 3.4.10, 3.4.20–3.4.21
interfering compounds, 3.4.18 (table)
method, 3.4.10–3.4.11
sample size and detection range, 3.4.22 (table)
in gel electrophoresis
blot transfer membrane staining, 10.8.2, 10.8.6–10.8.7
continuous nondenaturing, 10.3.3
denaturing discontinuous, 10.1.7
SDS-PAGE, 10.1.32
sensitivity and membrane compatibilities, 10.8.1 (table)
protein detection in polyacrylamide gels
acid-based Coomassie brilliant blue G-250, 10.5.3, 10.5.11
Coomassie brilliant blue R-250, 10.5.1–10.5.2, 10.5.11
rapid Coomassie brilliant blue R-250 staining, 10.5.2–10.5.3, 10.5.11
recipes, 10.5.9, 10.5.10
two-dimensional gel electrophoresis, 10.4.30, 10.4.36
Cooperative binding, in ligand-binding theory, A.5A.25–A.5A.27, A.5A.36
Copper ion–dependent assays for total protein, 3.4.17–3.4.18
Copper ions, 5.6.2, 9.4.12–9.4.13
Copy number, 5.6.2, 5.8.14
Corey-Pauling α-helical geometry, 2.3.1
CORT (cloning of receptor targets), 19.3.7
Cosolvents, in folding of recombinant proteins, 6.4.4, 6.4.5, 6.4.6, 6.5.3
Cotransfection, of selectable markers, 5.9.6
Cotranslational folding, 14.1.1
Coupling methods, for synthetic peptides
using a carbodiimide, 18.3.13
comparison of methods, 18.3.1, 18.3.15–18.3.16
design of peptide and, 18.3.5–18.3.7
using heterobifunctional reagent, 18.3.8–18.3.9
using homobifunctional reagent, 18.3.12
photochemical, 18.3.13
Covalent modification, of recombinant proteins expressed by mammalian cells, 5.9.10
CRD (cross-reacting determinant), 12.5.7, 12.5.11, 12.5.12
Cresol compounds, Folin assay for, 3.4.16
Cross-linked proteins, purification
detergents in, 1.3.5
strategies, 1.2.3
Cross-linking reagents, for coupling synthetic peptides to carrier proteins, 18.3.1, 18.3.8–18.3.9, 18.3.12–18.3.13, 18.3.15–18.3.16
Cross-reacting determinant (CRD), 12.5.7, 12.5.11, 12.5.12
Crowding agents, in protein precipitation, 4.5.15–4.5.16, 4.5.30–4.5.32
Cryo-electron microscopy, 17.2.17 (fig.), 17.2.18–17.2.19
Cryopreservation, *see* Freezing of cells
Crystallization, in protein characterization, 1.1.5, 6.1.16, 6.1.18
Crystallography, *see* X-ray crystallography
Crystals, two-dimensional, visualization by electron microscopy, 17.2.15, 17.2.19–17.2.20
CSA, *see* D-(+)-10-Camphorsulfonic acid
C-terminal polypeptides, functionality after cleavage, 18.4.2 (table), 18.4.18
C-terminal residue and sequencing, UNIT 16.7
C-terminal sequences
analysis of
automated, 11.8.1–11.8.2, 11.8.4–11.8.13
manual, 11.8.3–11.8.4, 11.8.6–11.8.13
chemical cleavage at
of Met residues with CNBr, 11.4.1–11.4.2, 11.4.5–11.4.8, 11.5.1–11.5.2
of Trp residues with BNPS-skatole, 11.4.2–11.4.3, 11.4.5–11.4.8, 11.5.4–11.5.5
in mammalian cells, 5.9.9
proteolysis in defining domain, 17.3.12
in recombinant expression systems, 6.1.4
C-terminal sequencing
automated
of bovine β-lactoglobulin A, 11.8.9 (fig.)
of BSA, 11.8.11 (fig.)
chemistry of, 11.8.2, 11.8.5 (fig.), 11.8.5–11.8.6
HPLC in, 11.8.2, 11.8.6
of human serum albumin, 11.8.10 (fig.)
instrumentation for, 11.8.1
protein profiles, 11.8.9 –11.8.12 (figs.)
sample preparation for, 11.8.1–11.8.2, 11.8.8
manual, using carboxypeptidases
buffers for, 11.8.8
carboxypeptidase specificity for amino acids, 11.8.7 (table), 11.8.7–11.8.8
controls for, 11.8.8
method, 11.8.3–11.8.4
sample preparation for, 11.8.3, 11.8.8
sample profile, 11.8.13
time points for experiments, 11.8.8
See also Hewlett-Packard G1009 A C-terminal sequencing system *and* Carboxypeptidases
Cu^{2+}, *see* Copper ions
Culture media, for tissue culture, A.3C.1, A.3C.3–A.3C.4, A.3C.11–A.3C.12 (recipes)
Culture of mammalian cells
permeabilization, 13.8.3–13.8.5
$^{32}P_i$ labeling and lysis for immunoprecipitation, UNIT 13.2
technique, APPENDIX 3C

CUP1 promoter, 5.6.2
Cyanate scavengers, 6.1.14
Cyanides
detection, A.2A.11–A.2A.12
disposal, A.2A.11
1-Cyano-4-dimethylaminopyridinium tetrafluoroborate, inactivating matrix hydroxyl function, 9.3.2 (table)
Cyanogen bromide (CNBr)
activation of Sepharose with, 9.5.6–9.5.7, 9.5.9–9.5.10
in bioligand-matrix coupling, 9.3.2, 9.3.4–9.3.5, 9.3.11–9.3.13
in cleavage at C-terminus of Met residues
on membranes, 11.5.1–11.5.3
in solution, 11.4.1–11.4.2, 11.4.5, 11.4.7
in cleavage in gels, 11.3.9–11.3.10
disposal, A.2A.11
safety precautions, 9.3.2, 9.5.6
Cyclic AMP–dependent protein kinase (cAPrK), in specific radioactivity determination, 13.8.14–13.8.15
Cyclic nucleotide–dependent protein kinases, assay for, 13.7.4–13.7.5
Cyclin, 17.1.13
Cyclohexamide, in mammalian cell culture for protein expression, 5.9.13
Cyclohexylaminopropanesulfonic (CAPS) buffer, in electroblotting, 10.7.12–10.7.13
Cys-A, *see* Cysteic acid
Cys mutation in protein synthesis, 18.4.1
Cysteic acid (Cys-A), for capillary electrophoresis
characterized, 10.13.1–10.13.2
conductivity and pH profiles
urea, 10.13.4 (fig.)
water, 10.13.3 (fig.)
Cysteine
absorption maxima and molar absorptivity, 3.1.4 (table)
cleavage with 2-nitro-5-thiocyanobenzoic acid, 11.4.6
in genome sequence alignment, 2.5.15–2.5.17
IAEDANS, reaction with, 10.6.3, 10.6.7, 10.8.7
labeling
biotin, 3.6.6–3.6.8
carbon or hydrogen, 3.3.13
iodination, 3.3.2 (fig.)
strategy, 3.3.1 (table)
modification of
by air oxidation, 15.1.11, 15.1.16
by alkylation, 15.1.3–15.1.6, 15.1.8–15.1.9, 15.1.11, 15.1.16
desalting of sample following, 15.1.14
by oxidation with performic acid, 15.1.10, 15.1.16
reactions for, 15.1.16 (fig.)
reagents for, 15.1.2 (table)
in samples of unknown composition, 15.1.5
selection of methods for, 15.1.1–15.1.3
in small samples, 15.1.5
by sulfitolysis, 15.1.9
by treatment with *N*-(iodoethyl)-trifluoroacetamide, 15.1.7
quantititation of in amino acid analysis, 11.9.23–11.9.25
in recombinant proteins
effect on gel filtration, 6.3.12
in interleukin 1β, 6.2.12
reduction
and alkylation, 11.3.7, 11.4.6–11.4.7, 11.5.8
in glycoconjugate labeling, 12.2.13
method for synthetic peptides, 18.3.10 (fig.), 18.3.11–18.3.12
in recombinant proteins, 6.1.14

UCSF / CENTRAL UNIVERSITY LIBRARY

residue, in genome sequence alignment, 2.5.15–2.5.17
in synthetic peptide design for antibody production, 18.3.5–18.3.7
X-ray crystallography samples and, 17.3.12–17.3.13

molecular weight, A.1B.2
phenol-containing, A.1B.2
physical properties of, A.1B.1 (table)
in protein elution from PVDF membranes, 10.7.9–10.7.10, 10.7.11–10.7.12, 10.7.13
in purification of proteins, 1.2.3, 1.3.5
recombinant proteins and
folding, 6.1.14
inclusion body extraction, 6.3.8–6.3.9
stability of protein, 6.1.16
removal or exchange of, A.1B.3
in total protein assays, 3.4.2, 3.4.19
Deuterium oxide gradient fractionation
applications, 4.2.46–4.2.47
merits and limitations, 4.2.3
method, 4.2.18–4.2.19
requirements, 4.2.50
Development, phosphorylation in regulation of, 13.1.1
Dextran
beads, 13.5.6–13.5.7
in gel-filtration chromatography column calibration, 6.2.8
reference standard, molecular size of proteins, 8.3.19
Dextran-iron conjugates, 4.2.48
DHFR, *see* Dihydrofolate reductase
Diafiltration, 4.4.6–4.4.8, 4.4.11, 4.4.12
Diagonal gel electrophoresis, 10.4.25–10.4.26
Dialysis
applications, 4.4.1
in desalting and buffer exchange, through regenerated cellulose tubing, 4.4.1–4.4.4, 4.4.10
large-volume, A.3B.1–A.3B.2

in ligand-binding theory, A.5A.6 (fig.), A.5A.9–A.5A.10
membrane
preparation, A.3B.3
selection and characteristics, 4.4.9–4.4.12
of protein samples, 3.4.12–3.4.13
small-volume, A.3B.2–A.3B.3
tubing, pretreated, 4.4.1–4.4.2, 7.3.16, A.3B.3
by ultrafiltration
concentration polarization, 4.4.11
rejection of solute, 4.4.11
tangential-flow, 4.4.6–4.4.8, 4.4.11
through asymmetric membrane disks, 4.4.4–4.4.6, 4.4.12 (table)
volume of filtrate for, 4.4.11
Diaminobenzidene (DAB)
detection of, A.2A.10
disposal, A.2A.7–A.2A.9
in immunoblot visualization, 10.10.5 (table)
in labeling endocytic compartments, 4.2.48
spills, A.2A.9
o-Dianisidine, 4.3.7
Diastereoisomers, defined, 12.1.6
DIC, *see* Diisopropylcarbodiimide
Dichlorodimethylsilane, disposal of, A.2A.11
Dichroism, circular, *see* Circular dichroism
Diethylaminoethyl (DEAE), in ion-exchange chromatography, of recombinant proteins, 6.1.9 (fig.)
Difference imaging, in electron microscopy, 17.2.20
Difference sedimentation, of recombinant proteins, 7.1.4 (table)
Differential centrifugation
by equilibrium
merits and limitations, 4.2.2
method, 4.2.9–4.2.11
requirements, 4.2.49
of recombinant proteins, 6.1.4, 6.1.6 (fig.)
by velocity
applications, 4.2.45–4.2.46
merits and limitations, 4.2.1
method, 4.2.7–4.2.9
requirements, 4.2.49
Differential scanning, of recombinant proteins, 7.1.4
Differential scanning calorimetry (DSC), measuring protein thermostability
buffer solutions, 7.9.6–7.9.7
DSC cells
maintenance and cleaning of, 7.9.5–7.9.6
pressure in, 7.9.7
heat capacity profile
interpretation of, 7.9.8–7.9.9
partial, 7.9.8
single endotherm, 7.9.9–7.9.13
instruments, calibration of
electrical, 7.9.4
temperature, 7.9.4–7.9.5
process overview, 7.9.2–7.9.4
protein purity, 7.9.6
strategic planning, 7.9.1–7.9.2 (table)
Differentiation, phosphorylation in regulation of, 13.1.1
Diffusion
in chromatography, 8.1.8
in dialysis, 4.4.10
Digestion
enzymatic
for amino acid sequencing, UNIT 16.7
in MCAC, 9.4.14
of proteins
in gel slices from SDS-PAGE, 7.3.6
for peptide mapping, 7.3.4
of oligosaccharides, endoglycosidase and glycoamidaserelease, UNIT 12.4
See also Chemical cleavage *and* Enzymatic digestion
Digestion buffers for enzymes, 11.1.2 (table), 11.2.2 (table)
Digital electrophoresis analysis
databases, 10.12.12–10.12.13
documentation and analysis
accuracy, 10.12.1
cost, 10.12.2
ease of handling, 10.12.1
reproducibility, 10.12.1–10.12.2
image capture
altering settings, 10.12.3 (fig.)
devices, 10.12.5, 10.12.6 (table)
process of, 10.12.5–10.12.8
imaging, key terms for
brightness, 10.12.2
contrast, 10.12.2
dynamic range, 10.12.2
gamma, 10.12.2
resolution, 10.12.4–10.12.5
saturation, 10.12.4
matching, 10.12.11–10.12.12
one-dimensional analysis, software for
background subtraction, 10.12.9
band detection, 10.12.8–10.12.9
characterization, 10.12.9–10.12.10
lane positioning, 10.12.8
two-dimensional analysis, software for
characterization, 10.12.12
spot detection, 10.12.10–10.12.11
Digital image processing and electron microscopy, 17.2.1–17.2.2
Digitonin, in
density shift centrifugation
applications, 4.2.48
merits and limitations, 4.2.6
method, 4.2.35–4.2.37, 4.2.38 (fig.)
requirements, 4.2.51
for lysis of radiolabeled cells, 13.2.7
Dihydrofolate reductase (DHFR)
amplification with methotrexate (MTX), recombinant protein production in mammalian cells, 5.10.10–5.10.11, 5.10.38
mammalian cell production and cell cycle, 5.9.12
as marker in mammalian expression systems, 5.9.5, 5.9.6
as selectable marker in mammalian expression systems, 5.9.6
2,5-Dihydroxybenzoic acid (DHB)
in mass spectrometry, 16.1.6, 16.2.3 (fig.)
matrix, for MALDI-MS, 16.3.1
Diisopropylcarbodiimide, activator for peptide synthesis, 18.2.13–18.2.15
Diisopropyl fluorophosphate (DFP), A.2A.12–A.2A.13
Dimyristoyl phosphatidylinositol, 12.5.10
Dinitrosalicylate, calibration plots for spectrophotometric assays, 3.4.17 (table)
Diode-array spectrophotometers
advantages of, 7.2.14, 7.2.16
using HPLC with in recombinant protein analysis, 7.2.10–7.2.12, 7.2.15–7.2.17
impure vs. pure proteins, 7.2.17, 7.2.18 (fig.), 7.2.19 (fig.)
temperature, 7.2.14–7.2.15
Dioxetane phosphate, in immunoblot visualization, 10.10.5 (table), 10.10.6, 10.10.8
Direct intracellular expression, in *E. coli* expression systems, 5.1.2–5.1.3
Discontinuous gel electrophoresis
denaturing, 10.1.3–10.1.9, 10.1.29
nondenaturing, native, and molecular weight standard curves, 10.3.5–10.3.7, 10.3.8 (fig.), 10.3.9
Discontinuous gradient, in differential centrifugation by equilibrium, 4.2.9–4.2.10
Disinfectants, for biohazards, A.2A.2
Disposal of hazardous chemicals, A.2A.2 (table)
Dissociation, in ligand-binding theory, A.5A.3
Dissociation constants
for protein-protein interactions, 19.1.2 (table)
rate constant k_{dissoc}, 19.1.3
Distance measures in sequence analysis, 2.1.2
DISTANCES (software), 2.1.10, 2.1.11 (fig.)
Distribution coefficient K_D, GF chromatography, 8.3.20
Disulfide array, peptide mapping in detection, 11.1.11
Disulfide-bond formation, analysis of
in vivo
in monolayer cells, 14.1.1–14.1.3, 14.1.13
post-translational, 14.1.4–14.1.5
in suspension cells, 14.1.3–14.1.4
in microsomes
method for, 14.1.5–14.1.7, 14.1.12–14.1.13
post-translational, 14.1.7
Disulfide bonds
contribution to circular dichroism, 7.6.1, 7.6.18
in expression systems, 7.1.8
in folding
formation of, 5.9.8–5.9.9
of growth hormones, 6.5.18–6.5.20
of interleukin 2, 6.5.8–6.5.9, 6.5.20
pathways, 6.4.1–6.4.2
in stability, 6.4.2–6.4.5
in recombinant proteins
in folding, 6.1.15
preventing formation, 6.1.14, 6.3.12
purification of, 1.3.1–1.3.2
in solubility and stability, 6.1.16
reduction of, 3.6.7–3.6.8
Disulfide isomerase, 1.3.2, 5.6.6, 6.1.15
Disulfide linkage pattern, confirming, in recombinant proteins, 7.3.8–7.3.12, 7.3.18, 7.3.20–7.3.23
5,5′-Dithiobis-(2-nitrobenzoic acid) (Ellman reagent), 15.1.13
Disulfides, reduction method for synthetic peptides, 18.3.10 (fig.), 18.3.11–18.3.12
Dithiothreitol (DTT)
for cleaving disulfide bonds, 15.1.2
for cysteine reduction, 18.3.11–18.3.12
in gel electrophoresis, 10.1.4, 10.1.29–10.1.30
in IAEDANS modification of proteins, 10.6.7, 10.8.7
in mammalian cell culture for protein expression, 5.9.13
for X-ray crystallography sample preparation, 17.3.7, 17.3.11, 17.3.12–17.3.13
Divinyl sulfone, in activating matrix hydroxyl function, 9.3.2 (table)
DMSO/PPO solution, in isoelectric-focusing slab gels, 10.2.5, 10.2.8
DNA
affinity chromatography, 9.6.8–9.6.10
competitor, nonspecific
selection and preparation of, 9.6.10

SCUASU / CENTRAL UNIVERSITY LIBRARY

in baculovirus expression system, 5.4.1, 5.4.2 (fig.), 5.4.3
binding
motifs and domains, 17.1.13–17.1.20
by phage-based expression cloning, UNIT 19.3
repression assay for, 19.2.9 (fig.)
butanol precipitation of, A.4E.2
detection of
and elimination of, 7.1.2
with restriction endonuclease buffers, A.4I.3
single sample, with single restriction endonuclease, A.4I.1–A.4I.3
enzymatic amplification of, by PCR, A.4J.2–A.4J.5
enzymes in replication and transcription, 17.1.29–17.1.32
ethanol precipitation of, A.4E.1
hydroxylapatite chromatography of, 8.6.2 (table), 8.6.7–8.6.9
phenol extraction of, A.4E.1
plasmid, conversion from recombinant phages, 19.3.2
polylinkers, in thioredoxin gene fusion expression vectors, 6.7.1, 6.7.2 (fig.)
purification and concentration
agarose gel electrophoresis, A.4F.1–A.4F.2
from aqueous solutions, A.4E.1–A.4E.2
recombinant
expression in chemical polypeptide synthesis, 18.4.2
vaccinia virus, 5.13.8–5.13.9
replication, kinetics of, 19.1.4
shearing, by sonication, 19.2.28–19.2.29
UV absorption spectroscopy of, 7.2.13–7.2.14
See also Plasmid DNA
DNA sequence
cDNA sequence databases, 2.5.4
search with BLAST, UNIT 2.5
cDNA library
expression, UNIT 19.3
expression cassette, pJG4-5, 19.2.35–19.2.36
screening, 19.2.34
DNA-binding proteins, purification using biotin/streptavidin affinity systems, UNIT 9.7
DNase, in recombinant protein extraction, 6.1.7, 6.5.3
DNAase I footprinting, affinity chromatography, 9.6.10, 9.6.13, 9.6.15
DNS, *see* Dinitrosalicylate
DNASTAR (software), 2.3.13 (table)
Dog pancreas microsomes, 14.1.5–14.1.6, 14.1.13
Dol-P-mannose, 12.5.10
Domain names, internet, 2.4.1, 2.4.2 (table)
Dot-blot hybridization, recombinant vaccinia virus
DNA detection, 5.14.5–5.14.6
expressed protein detection, 5.14.6–5.14.7
Dot plots, 2.1.3, 2.1.4 (fig.)
Double matching probability function, 2.1.10
Double-reciprocal plot
characterized,3.5.6 (fig.), 3.5.8–3.5.9
of rectangular hyperbolic binding equation, A.5A.7 (fig.)
Double-stranded RNA-binding domain (dsRBD), 17.1.22
DPPD, in gradient fractionation using Percoll, 4.2.16
Dried drop method, of sample preparation for MALDI-MS, 16.3.1–16.3.2
Dropout medium for yeast growth
for interactor hunts, 19.2.34
plates, complete minimal (CM) medium, selecting a library plasmid with, 19.2.11
powder, CM medium (recipe), A.4L.2
plates, CM medium (recipe), A.4L.3
Drug resistance genes
generally, 5.6.3, 5.7.5, 5.7.6 (table), 5.7.8, 5.7.10 (fig.)
for mammalian expression systems, 5.9.6
Drying gels, 10.5.2
Dry weight determination, in total protein quantitation
interfering compounds, 3.4.18 (table)
method, 3.4.11–3.4.12
sample size and detection range, 3.4.22 (table)
DSA, in glycoprotein purification, 9.1.2 (table)
DSCE (software), 2.1.8
DTT, *see* Dithiothreitol
Duct cell plasma membane marker, 4.2.34
Duffy blood group system, 11.3.9
Dunhill's helical net method of secondary structure prediction, 2.3.2
DUST filtering program, for BLASTN, 2.5.28
Dye affinity chromatography
advantages of, 9.2.13
component selection, using
centrifugation, 9.2.4–9.2.6
chromatography, 9.2.1–9.2.4
detergents, nonionic, in, 9.2.13–9.2.14
eluting protein, 9.2.15
immobilized dyes
commercially available, 9.2.2 (fig.)
electrostatic charges, 9.2.14
ionic strength of application solvent, 9.2.13–9.2.14
negative, 9.2.6–9.2.7
positive, using
batch elution, 9.2.7–9.2.8
gradient elution, 9.2.8–9.2.9
reactive dyes
commercially available, 9.2.12 (table)
immobilization, 9.2.10–9.2.13
structures, 9.2.11 (fig.)
retaining protein, 9.2.14–9.2.15
tandem, 9.2.9–9.2.10
types of, 9.2.1
Dye-binding assays, *see* Coomassie blue, dye–binding assay
Dye-matrix screening kits, 6.1.10
Dynamic capacity, for column purification
defined, 8.2.8
measurement of, 8.2.20–8.2.21
media compared, 8.2.5–8.2.7 (table)
Dynamic light scattering, *see* Light scattering

in glycoprotein cleavage
comparison of, 12.4.5 (fig.)
endoglycosidase D, 12.4.14
endoglycosidase F_2, 12.4.3–12.4.4, 12.4.13–12.4.14, 12.4.15
endoglycosidase H, 12.4.2–12.4.3, 12.4.12–12.4.13, 12.4.15
estimating N-linked oligosaccharide chains, 12.4.6–12.4.7
gel filtration of released N-linked oligosaccharide chains, 12.4.8–12.4.12, 12.4.15
purchasing or purifying enzyme, 12.4.14
specificities, 12.4.1
strategy, 12.4.1
sugar chains in, 12.4.4 (fig.)
in oligosaccharide cleavage, 12.3.5–12.3.6, 12.3.8
Endoplasmic reticulum
density gradient electrophoresis, 4.2.30
density shift using digitonin, 4.2.36, 4.2.38 (fig.), 4.2.48
endoglycosidase H sensitivity, 12.4.12–12.4.13
fractionation, 4.1.8 (table)
gel filtration, 4.2.47
glycosylation in, 5.6.5
in protein synthesis, 5.9.7–5.9.10
in rat pancreas, 4.2.15 (fig.)
Endoprotease Lys-C, for in-gel digestion of proteins, 16.4.4
Endoproteases, *see* Proteases
Endoproteinase Asp-N
conditions for activity, 11.1.2 (table)
proteolysis of undenatured substrates, 11.1.6 (table)
specificity of digestion, 11.1.12 (table)
Endoproteinase Glu-C
conditions for activity, 11.1.2 (table)
in digestion on PVDF membranes, 11.2.2 (table), 11.2.4–11.2.5
proteolysis of undenatured substrates, 11.1.6 (table)
sequence analysis of, 11.1.17 (table)
specificity of digestion, 11.1.12 (table)
Endoproteinase Lys-C
buffer compatibilities, 11.1.13–11.1.16
compatibility with other proteases, 11.1.13–11.1.16
conditions for activity, 11.1.2 (table)
in digestion on PVDF membranes, 11.2.2 (table), 11.2.4–11.2.5
proteolysis of undenatured substrates, 11.1.6 (table)
sequence analysis of, 11.1.17 (table)
specificity of digestion, 11.1.12 (table)
Endosomal carrier vesicles (ECV), 4.3.2 (table), 4.3.4, 4.3.14, 4.3.15–4.3.16, 4.3.18
Endosomes
composition and morphology, 4.3.18–4.3.19
density shift using colloidal gold conjugates, 4.2.40
electrophoresis, 4.2.27–4.2.29, 4.2.30 (fig.), 4.2.47
fractionation, 4.1.8 (table), UNIT 4.3
fusion events in in vitro fusion assay, 4.3.8, 4.3.15–4.3.16
labeling conditions for characterization, 4.3.2 (table)
latency, 4.3.7
Endotoxins
detection and elimination, 7.1.2
in recombinant protein contamination, 6.1.17
End-point assay, in baculovirus expression system, 5.5.8–5.5.9
Engineering, *see* Protein engineering
Enhanced chemiluminescence, in anti-phosphotyrosine antibody detection, 13.4.3–13.4.5
Enterokinase
in fusion protein cleavage, 5.1.6
in thioredoxin fusion protein cleavage, 6.7.1, 6.7.2 (fig.), 6.7.4
Enthalpy
and equilibrium, protein-protein interactions, 19.1.3
protein thermostability, 7.9.10–7.9.13
Entrez database links, 2.5.11
Enzymatic cleavage, in N-terminal methionine removal, 6.1.3
Enzymatic digestion
capillary electrophoresis in monitoring, 10.9.1, 10.9.11–10.9.13
in gels
amino acid analysis of SDS-PAGE proteins, 11.3.6–11.3.7
CNBr in, 11.3.9–11.3.10
concentration of protein in, 11.3.1 (table), 11.3.8–11.3.9
database searching in sequencing, 11.3.12
density of protein in, 11.3.9
glycosylation in resistance to, 11.3.9

COAST CENTRAL UNIVERSITY LIBRARY

laser desorption mass spectra in sequencing, 11.3.11
reduction and alkylation of SDS-PAGE proteins, 11.3.7
with SDS, 11.3.4–11.3.5, 11.3.8
of transferrin, 11.3.9, 11.3.11 (fig.)
trypsin and lysyl endopeptidase in, 11.3.7–11.3.8
with Tween 20, 11.3.1–11.3.4, 11.3.8
without detergent, 11.3.5–11.3.6
of GPI-containing proteins, 12.5.5–12.5.7, 12.5.11–12.5.12
of histidine tags, 6.5.13, 6.5.21, 6.5.22–6.5.23
in MCAC, 9.4.14
of oligosaccharides, endoglycosidase and glycoamidase release, 12.3.5–12.3.6, UNIT 12.4
in phosphorylation detection
with acid phosphatase, 13.5.2–13.5.3
with alkaline phosphatase, 13.5.3
applications, 13.5.1
^{32}P measurement and identification, 13.5.5, 13.5.6
with protein serine/threonine phosphatases, 13.5.3–13.5.4
with protein tyrosine phosphatases, 13.5.4
strategy, 13.5.1–13.5.2, 13.5.5–13.5.7
on PVDF membranes, UNIT 11.2
in solution
endoprotease activity, conditions for, 11.1.2 (table)
limited and partial digestion, 11.1.16
under nondenaturing conditions, 11.1.1, 11.1.3
peptide mapping, 11.1.11
protease compatibilities, 11.1.13–11.1.16
protease-resistant proteins, 11.1.6 (table), 11.1.11, 11.1.13, 11.1.15 (fig.), 11.1.16
protease specificities, 11.1.11
protease stock preparation, 11.1.7–11.1.9, 11.1.13
reduction and alkylation of peptides in digest mixtures, 11.1.10
SDS in, 11.1.5–11.1.7, 11.1.15–11.1.16
urea or guanidine·HCL in, 11.1.4–11.1.5, 11.1.13–11.1.16
Enzymatic sequencing, UNIT 16.7
Enzymes
aminopeptidase M, for ladder sequencing, UNIT 16.7
in baculovirus expression systems, nutrient level monitoring assay, 5.5.12–5.5.13
calibration plots for biuret assay, 3.4.2 (table)
carboxypeptidase A, P, and Y, for ladder sequencing, UNIT 16.7
characterization, properties in, 1.1.5
endoprotease-Lys-C, 16.4.4
in folding of proteins, 6.4.1–6.4.2, 6.4.4
functional assessment, 8.1.2
in fusion protein cleavage, 5.1.5–5.1.6
iodination using, 3.3.6–3.3.7
kinetics, assays of, UNIT 3.5
as markers
in density gradient electrophoresis, 4.2.30 (fig.)
in density shift using digitonin, 4.2.36, 4.2.38 (fig.)
in density shift using gold conjugates, 4.2.48
in gradient fractionation using non-ionic iodinated solutes, 4.2.22
for lectin adsorption, 4.2.34, 4.2.35
in subcellular fractionation, 4.3.1–4.3.3, 4.3.14, 4.3.18
in zonal centrifugation, 4.2.15 (fig.)
oligosaccharide and glycosylation inhibition, 12.3.2 (table) 12.3.3 (fig.), 12.3.8
in phosphorylation
digestion of phosphoproteins, UNIT 13.5
kinases, 13.1.3
labeling studies of, 13.1.1–13.1.2
phosphatases, 13.1.3–13.1.4
post-translational modifications in insect cells, 5.4.3
proteases, in SDS-PAGE, 10.1.7, 10.1.32–10.1.33
purification, for industry vs. research, 1.1.1
purification strategies, of intracellular, 1.2.2
purification table, 8.1.3 (table)
recombinant
folding and purification, 6.5.10–6.5.14, 6.5.21–6.5.25
gel filtration in guanidine hydrochloride, 6.3.12–6.3.15
in recombinant expression systems
inclusion body formation, 6.1.3
in viscosity and proteolysis, 6.1.7, 6.1.10
in recombinant protein extraction, 6.5.3
recombinant proteins and, in folding, 6.1.15
structure of, 17.1.29–17.1.32, 17.1.33–17.1.38
T7 RNA polymerase promoter system, 5.1.2, 5.2.5, 5.2.6, 5.2.15
Enzyme-substrate interactions
enzyme-substrate complexes, in ligand-binding theory, A.5A.3
enzyme-to-substrate ratio, in enzymatic digestion on PVDF membranes, 11.2.2
rate of dissociation, 19.1.4
Epichlorohydrin, in activating matrix hydroxyl function, 9.3.2 (table)
Epimers, defined, 12.1.6
EPO-R, *see* Erythropoietin EPO receptor
Epoxides, in activating matrix hydroxyl function, 9.3.2 (table)
Equilibria
in differential centrifugation, merits and limitations, 4.2.2
in ligand-binding theory
binding responses, interplays of, A.5A.27–A.5A.30
equilibrium binding event, for rectangular hyperbolic response, A.5A.3
equilibrium constants, in terms of dissociation, A.5A.3
partition equilibrium variants of quantitative affinity chromatography, A.5A.17
sedimentation equilibrium, A.5A.31–A.5A.32
spectral signal from ligand, A.5A.13–A.5A.15
timing and, A.5A.36
parameters, in protein interactions, 19.1.1–19.1.3
Equilibrium association constant K_a, protein-protein interactions, 19.1.2
Equimolar iodination, 3.3.7, 3.3.9
Equipment, *see* Laboratory equipment
Equivalent hydrodynamic radius (rH), 7.8.10
Erythropoietin, expression in CHO cells, 5.9.12
Erythropoietin EPO receptor, expression by mammalian cells, 5.9.10
Escherichia coli
electroporation transfer to, 19.2.19–19.2.20, 19.2.23
extracts, protein purification from, 19.3.1, 19.3.7
interaction trap components, 19.2.4–19.2.5 (table)
Escherichia coli expression systems
advantages and disadvantages, 6.1.5 (table)
for bacterial expression of α-thioester polypeptides, 18.4.12–18.4.15
fermentation and growth
batch methods, 5.3.1–5.3.8
centrifuge, 5.3.4 (fig.)
equipment, 5.3.2 (table), 5.3.3 (fig.), 5.3.15–5.3.16
fed-batch methods, 5.3.8–5.3.9, 5.3.14–5.3.16, 5.3.17 (fig.)
harvesting, 5.3.7, 5.3.16
in vivo labeling with heavy isotope derivatives, 5.3.9–5.3.10
monitoring, 5.3.11–5.3.12
stable isotopic labeling, 5.3.10–5.3.11, 5.3.16
sterility checking, 5.3.12, 5.3.15–5.3.16
strategy choice, 5.3.14–5.3.15
temperature, 5.3.13
folding of proteins, UNIT 6.4
for GST fusion proteins, 6.6.1–6.6.7
host-vector system characteristics, 6.1.2–6.1.4
inclusion body preparation and extraction, 6.1.11–6.1.15, 6.7.10, UNIT 6.3
optimizing, 6.2.10–6.2.11
plasmid purification, 5.10.3–5.10.5, 5.10.34
production
direct intracellular expression, 5.1.2–5.1.3
fusion protein cleavage methods, 5.1.5–5.1.6
fusion proteins, 5.1.3–5.1.4
fusion tags, 5.1.5
origin of replication, 5.1.1
promoters, 5.1.2
secretion, 5.1.3
selectable markers, 5.1.1
strategies, UNIT 5.1
translation initiation, 5.1.2
properties of proteins in, 1.2.4, 6.2.10–6.2.11
purification of proteins
of bovine growth hormone, interleukin 2, and HIV-1 integrase, UNIT 6.5
equipment, 6.1.18–6.1.19
protein handling, 6.1.16–6.1.17
scale of operations and aims of purification, 6.1.17–6.1.18
sequence and compositional analysis, 6.1.1–6.1.2
solubility and location of protein, 6.1.4–6.1.7
selection
criteria in, 5.2.14
extracellular medium sample preparation, 5.2.12, 5.2.15
for fermentation processes, 5.2.1
lac/tac promoter control, 5.2.4, 5.2.14–5.2.15, 5.2.16
periplasmic extract preparation, 5.2.11, 5.2.15
plasmid stability analysis, 5.2.7–5.2.8, 5.2.15
pL promoter control: temperature induction, 5.2.2–5.2.3, 5.2.14, 5.2.16
SDS-PAGE analysis, 5.2.9
solubility analysis, 5.2.10, 5.2.15
strain storage, 5.2.8–5.2.9

BOSTON UNIVERSITY MEDICAL CENTER LIBRARY

    protocol, 3.1.3
  in polyacrylamide gels
    fluorescamine, 10.6.5, 10.6.6–10.6.7
    IAEDANS modification of proteins, 10.6.3–10.6.4, 10.6.6–10.6.7, 10.6.8
    tryptophan, 10.6.7
  quenching of, 7.7.8–7.7.10, 7.7.12 (fig.), 7.7.13–7.7.16
  Raman band, 7.7.3 (fig.), 7.7.6 (fig.), 7.7.11
  Rayleigh band, 7.7.3 (fig.), 7.7.11
  in recombinant protein characterization, 7.1.6 (table), 7.1.7–7.1.8
  spectrometer, 7.7.1–7.7.2
  spectrum of a protein, determining, UNIT 7.7
  temperature dependence of, 7.7.4 (fig.)
Fluorescence polarization, for ligand-binding theory, A.5A.13–A.5A.14 (fig.)
Fluorescence spectrometer
  calibration, 7.7.1
  cuvettes for, 7.7.2
  use in recording fluorescence spectrum, 7.7.4–7.7.7
Fluorescence spectrum for characterizing protein conformation, UNIT 7.7
2-Fluoro-2-deoxy-D-glucose, 12.5.10
Fluorography
  exposure in autoradiography, 10.11.3–10.11.4
  of isoelectric-focusing slab gels, 10.2.5, 10.2.8
2-Fluoro-1-methyl-pyridinium tosylate, in activating matrix hydroxyl function, 9.3.2 (table)
FMC Isogel agarose, 4.2.25
Fmoc, *see* 9-Fluorenylmethylcarbonyl
Folding of proteins
  aggregation
    as competitor, 6.4.2
    limiting, 6.4.6
  cotranslational and post-translational, 5.9.8–5.9.9, 14.1.1, 14.1.4, 14.1.7, 14.1.13
  hydrophobic interactions in, 2.2.1
  in inclusion bodies, 5.1.3
  pathways, 6.4.1–6.4.2
  reagents for, APPENDIX 3A
  recombinant
    bovine growth hormone, 6.5.2–6.5.5, 6.5.18–6.5.25
    glycosylated vs. nonglycosylated, 6.1.15–6.1.16
    HIV-1 integrase, 6.5.10–6.5.14, 6.5.21, 6.5.22–6.5.25
    human interleukin 2, 6.5.6–6.5.8, 6.5.20, 6.5.22–6.5.25
    insoluble, 1.3.1–1.3.3
    monitoring, 6.1.15
    pellet preparation for, 6.3.3
    performing, 6.1.14–6.1.15
    strategy, 6.1.12 (fig.), 6.1.14–6.1.15, 6.5.1
  recovery after denaturation
    achieving acceptable rate, 6.4.6
    stabilizing native functional state, 6.4.2–6.4.6
  thermodynamic drive in, 6.4.1
Folin-Ciocalteau reagent, 3.4.3, 3.4.16
Formaldehyde
  in modification of amino groups, 15.2.11–15.2.13
  in silver staining, 10.5.6
Formic acid
  in cleavage of Asp-Pro bonds
    on membranes, 11.5.5
    in solution, 11.4.4, 11.4.7 (table)
  in RP-HPLC, 6.5.9
FPLC, *see* Fast protein liquid chromatography
Fractionation
  characterization, 7.10.1–7.10.3
  size-exclusion, for recombinant protein
  See also Cell fractionation
Fractionation range
  in HPLC chromatograph of α-actin recombinant protein, 7.10.8 (fig.)
  of prepacked columns for size-exclusion chromatography, 7.10.2 (table)
Free-flow electrophoresis, in subcellular fractionation, 4.3.13
Free ligand concentration, for ligand-binding theory
  in hyperbolic response of, A.5A.4–A.5A.8
  methods for illustrative analysis of experimental binding, A.5A.9–A.5A.11
Freeze-thawing
  in lysis of recombinant protein expression systems, 6.2.11
  two-dimensional gel electrophoresis, 10.4.35
Freezing of cells
  from monolayers, A.3C.6–A.3C.7, A.3C.13
  from suspension culture, A.3C.7
  thawing and recovering frozen cells, A.3C.7–A.3C.8
French press, 6.1.6 (fig.), 6.1.8, 6.1.13 (fig.), 6.1.18, 6.2.3–6.2.4, 6.2.13–6.2.14, 6.7.6–6.7.7
Frictional coefficient (*f*), 7.8.10–7.8.11
FTP, *see* File transfer protocol
L-Fucose (Fuc), defined, 12.1.6
Function, of proteins
  in classification, 1.2.1, 1.2.2 (table)
  sources of material for study of, 1.1.2–1.1.3
Functional analysis, of subcellular organelles, 4.3.15–4.3.16
Functional assays, of protein purity, 8.1.2–8.1.3
Functional sites, identification, 2.1.12–2.1.14
Furanoses, defined, 12.1.3, 12.1.4 (fig.)
Fusion proteins
  affinity purification, 18.4.8, 18.4.15
  analysis after protease cleavage using HPLC, 7.10.5 (fig.)
  in *E. coli* expression systems, 5.2.16
    attributes, 5.1.3–5.1.4
    cleavage methods, 5.1.5–5.1.6
    from *E. coli* BL21, 18.4.14
    purification methods, 5.1.5 (table)
  expression in recombinant systems, 6.1.4
  generation of, 18.4.2–18.4.3
  immunoblot analysis to confirm construction, 19.2.28
  lacZ, yeast strain containing, A.4L.4
  LexA binding domain, with GAL4 activation domain, 19.2.33–19.2.34
  MCAC of, UNIT 9.4
  thioredoxin, expression and purification of, UNIT 6.7
  See also GST fusion proteins
Fusion protein junction, in phage-based expression cloning, 19.3.1
Fusion tags, *see* Tags, fusion

G

G_1 phase, mammalian cell protein production and, 5.9.12
G418 (drug), 5.6.3, 5.7.5, 5.7.8, 5.8.14–5.8.15
GAL1 promoter, 5.6.2, 5.6.4
Galactose
  cyclic structures, 12.1.3, 12.1.4 (fig.)
  defined, 12.1.6
  in *S. cerevisiae* expression system, 5.6.4
Galactose/raffinose (GAL/Raff), yeast growth using, for interacting protein selection, 19.2.11
Galactose-regulated vectors for expression of proteins in *S. cerevisiae*
  large-scale, 5.8.6–5.8.8
  small-scale, 5.8.1–5.8.3
β-Galactosidase
  for *lacZ* gene activation, 19.2.8–19.2.9
  in liquid yeast culture, A.4L.4
  mammalian cell production and cell cycle, 5.9.12
  proteins, in phage-based interaction cloning, 19.1–19.2, 19.3.7

BOSTON UNIVERSITY MEDICAL LIBRARY

Galactosyltransferase
density gradient electrophoresis, 4.2.30 (fig.)
density shift using digitonin, 4.2.36, 4.2.38 (fig.)
metrizamide inhibition of, 4.2.21
in rat pancreas, 4.2.15 (fig.)
GalNAc, *see* *N*-Acetyl-D-galactosamine
Ganglioside, defined, 12.1.6
Garnier, Osguthorpe, and Robson (GOR) method of secondary structure prediction
applying, 2.3.8
basis of, 2.3.5–2.3.7
comparison with other methods, 2.3.11–2.3.18
human profilin I structure, 2.3.10 (fig.)
Gaussian curve, digital electrophoresis analysis, 10.12.10–10.12.11
GCG (Genetics Computer Group) software, 2.1.3, 2.1.8, 2.1.10–2.1.12, 2.3.13 (table)

GlcNAc, *see* *N*-Acetyl-D-glucosamine
GlcNAc transferase, *see* *N*-Acetylglucosaminyltransferase
Gliadin, capillary zone electrophoresis of from bread wheat flour, 10.13.11 (fig.) from durum wheat flour, 10.13.10 (fig.)
Globins, 17.1.39–17.1.40
Globular proteins, *see* Soluble proteins
Glossary of glycosylation terms, 12.1.6–12.1.8
Glu, *see* Glutamic acid
Glu-C endoproteinase, *see* Endoproteinase Glu–C
Glucosamine, 12.5.7
Glucose
defined, 12.1.6
glycoconjugate labeling, effects on, 12.2.9, 12.2.12–12.2.13
in mammalian cell culture for protein expression, 5.9.12–5.9.13
Glucose lactate, in insect cell–recombinant baculovirus co-culture, 5.5.12–5.5.13
Glucose-limited chemostat culture, 5.9.12
Glucose 6-phosphatase, 4.2.38 (fig.)
Glucose-repressible *ADH2* vectors for expression in *S. cerevisae*, 5.8.3
Glucose yeast growth, used for library plasmid selection, 19.2.11
Glucosidases, 12.3.2 (table), 12.3.3 (fig.), 12.3.8
Glucoside, in glycoprotein denaturation, 12.4.14
D-Glucuronic acid, defined, 12.1.6
Glutamate, cleavage in recombinant proteins, 7.1.10
Glutamic acid (Glu), for capillary electrophoresis
characterized, 10.13.1–10.13.2
conductivity and pH profiles
urea, 10.13.4 (fig.)
water, 10.13.3 (fig.)
Glutamine, in insect cell–recombinant baculovirusco-culture, 5.5.13
γ-Glutamyltransferase
in lectin adsorption, 4.2.34, 4.2.35
in rat pancreas, 4.2.15 (fig.)
Glutaraldehyde
in activating matrix hydroxyl function, 9.3.2 (table)
for coupling synthetic peptides to carrier proteins, 18.3.6, 18.3.10 (fig.), 18.3.12, 18.3.16
in silver staining, 10.5.4, 10.5.5
Glutathione
in disulfide bond formation, 6.1.12 (fig.), 6.1.15, 6.4.5, 6.5.22
in recombinant protein purification, 1.3.1–1.3.2, 6.5.3
Glutathione-*S*-transferase (GST)
batch purification, 6.6.11–6.6.12
cleavage to remove affinity tag
batch cleavage, 6.6.15
bound to affinity column, 6.6.14
cleavage products, purification, 6.6.15–6.6.17
in solution, 6.6.12–6.6.14
expression
induction of using IPTG, 6.6.5–6.6.7
pGEX vectors for, 6.6.1–6.6.5, 6.6.19
yield, 6.6.20–6.6.21
flow chart for, 6.6.2 (fig.)
generally, 5.1.4
insoluble (inclusion bodies), affinity purification of, 6.6.10–6.6.11, 6.6.20
moiety, elution position in HPLC protein analysis, 7.10.5 (fig.)
soluble, affinity purification of, 6.6.8–6.6.10, 6.6.20
for soluble protein expression, 6.7.10
Glutathionylation, 6.5.22
Glycan, 5.7.11, 12.5.1, 12.5.10
Glyceraldehyde
defined, 12.1.6
enantiomers of, 12.1.3
Glyceraldehyde-3-phosphate dehydrogenase, 5.6.3, 5.6.4 (fig.)
Glycerol
as centrifugation media, 4.1.5
in recombinant protein storage, 6.1.16
Glyceryl CPG glass beads, 4.2.22–4.2.23, 4.2.47
Glycine
in recombinant protein purification, 6.1.14
urea and, 11.10.8

NOT FOR RESALE / CENTRAL UNIVERSITY LIBRARY

Glycine–asparagine bonds (Gly-Asn), cleavage with hydroxylamine
on membranes, 11.5.5–11.5.6
in solution, 11.4.4–11.4.5, 11.4.7 (table)
Glycoamidases, in cleavage of glycoproteins
vs. endoglycosidases, 12.4.5 (fig.)
estimating N-linked oligosaccharide chains, 12.4.6–12.4.7
gel filtration of released N-linked oligosaccharide chains, 12.4.8–12.4.12, 12.4.15
procedure, 12.4.5–12.4.6
specificity, 12.4.1, 12.4.12–12.4.14
storage and pH, 12.4.15
strategy, 12.4.1
sugar chains in, 12.4.4 (fig.)
Glycobiology, defined, 12.1.1
Glycoconjugate analysis
advances in study of, 12.1.1
endoglycosidase and glycoamidase release of N-linked oligosaccharides, UNIT 12.4
glycosylation
inhibition, UNIT 12.3

mammalian cells for protein expression, 5.9.6, 5.9.10–5.9.14
monitoring in fermentation process, 5.3.11–5.3.12
specific growth rate, 5.9.12

BOSTON UNIVERSITY / CENTRAL LIBRARY

Growth factors
for mammalian cell culture, 5.9.11
in phosphorylation stimulation, 13.1.1
Growth hormone, *see* Bovine growth hormone
GROWTREE (software), 2.1.10, 2.1.11 (fig.)
GRP78, *see* BiP
GS115 *P. pastoris* strain, 5.7.3 (table), 5.7.4
GSL-1, in glycoprotein purification, 9.1.2 (table)
GSS (Genome survey sequence), 2.5.5
GST, *see* Glutathione S-transferase
GST affinity tag, 19.3.1, 19.3.8
GST-bait protein, ^{32}P-labeled, 19.3.1, 19.3.8
λgt11 expression vector, 19.3.1–19.3.2 (fig.)
GTPase rab5 protein, flotation-gradient fractionation of, 4.3.8–4.3.9, 4.3.14, 4.3.18
Guanidine·HCl, *see* Guanidine hydrochloride
Guanidine hydrochloride (Guanidine·HCl)
in aggregation, 6.4.6
concentration and reversible unfolding transition, 6.4.3–6.4.4
in cysteine modification, 15.1.2–15.1.3
in enzymatic digestion of proteins in solution, 11.1.2 (table), 11.1.4–11.1.5, 11.1.13–11.1.16
recombinant proteins and
bovine growth hormone extraction, 6.5.21
extraction of proteins, 6.1.4–6.1.5, 6.1.12 (fig.), 6.1.13–6.1.14
gel-filtration chromatography, 6.3.3–6.3.6, 6.3.8–6.3.15
removal of guanidine hydrochloride for SDS-PAGE, 6.3.6–6.3.7
RP-HPLC, 6.5.8–6.5.9
Guanidinium ion, 6.3.9
Guide strip staining, in protein detection in polyacrylamide gels, 10.6.7
Guzzo secondary structure prediction method, 2.3.1

H

^{2}H and ^{3}H-exchange, of recombinant proteins, 7.1.4 (table)
H (T) function, determination of, 7.9.1
Haloacyl reagents, alkylation of cysteine residues using
method, 15.1.3–15.1.5
reagents, 15.1.2 (table), 15.1.15
in samples of unknown composition, 15.1.5
in small samples, 15.1.5
Hames plot, of rectangular hyperbolic binding equation, A.5A.7 (fig.)
Hartree-Lowry assay
calibration plots, 3.4.4–3.4.5, 3.4.17 (table)
calibration standards and reagents, 3.4.18–3.4.19
interfering compounds, 3.4.18 (table)
method, 3.4.3–3.4.4
sample size and detection range, 3.4.22 (table)
Harvesting
in baculovirus expression system, 5.5.11, 5.5.17
in *E. coli* expression systems, 5.3.7, 5.3.16
Hash functions, 2.1.8
Haworth representation of monosaccharides, 12.1.4, 12.1.5
4HCCA (α-cyano-4-hydroxycinnamic acid)
in mass spectrometry, 16.1.6, 16.2.3 (fig.)
matrices
for MALDI mass analysis, 16.3.1
for PSD analysis, 16.6.6
purification/recrystallization of, 16.3.3–16.3.4
Heat-sealing glass tubes, 3.4.8–3.4.9
Heat-shock proteins
crystallizable domains, 17.3.12
in *E. coli* expression systems, 5.2.1, 5.2.16
in folding of proteins, 5.9.8 (fig.), 5.9.9
isolation of heat shock protein 70, in interactor hunts, 19.2.34
Heat treatment, for fusion protein purification, 6.7.8–6.7.9
Heavy metal clusters, for labeling in electron microscopy, 17.2.21, 17.2.22 (fig.), 17.2.24
Heavy metals, 4.4.10, 6.4.5
HEC, *see* Hydroxyethyl cellulose
HeLa cells, for recombinant protein expression, 5.9.3 (table), 5.9.4
Helical net method of secondary structure prediction, 2.3.2
Helical wheel method of secondary structure prediction
applications, 2.3.1–2.3.2
basis of, 2.3.7–2.3.8
Helices
amino acid positional preferences in, 2.3.5
characteristics, 2.3.11 (table)
Chou and Fasman prediction rules, 2.3.11 (table)
conformational preference parameters, 2.3.3–2.3.5
in hemoglobin, IL-1β, and profilin, 2.3.4 (fig.) 2.3.12–2.3.14, 2.3.18 (fig.)
Helix-loop-helix motifs, 17.1.18
Helix-turn-helix motifs, 17.1.13, 17.1.16
Hemacytometer, A.3C.8–A.3C.10, A.3C.13
Hemiacetal, defined, 12.1.3
Hemiketals, defined, 12.1.3, 12.1.4 (fig.)
Hemoglobin
hydropathy profile, 2.2.7, 2.2.8 (fig.)
secondary structure prediction
Chou and Fasman method, 2.3.4 (fig.)
comparison of methods, 2.3.11–2.3.18
Hemoglobin Knossos, capillary zone electrophoresis of, 10.13.12 (fig.)
Hen egg white lysozyme, hydropathy profiles, 2.2.2 (fig.)
Henderson-Hasselbach relationship, 6.1.2
Heparin-agarose chromatography, 9.6.15
Hepatic microsomes, metoprolol uptake in membrane-receptor interactions, A.5A.33–A.5A.37
Hepatitis B surface antigen, formation in murine cells, 5.9.9
HEPES, in permeabilization, 13.8.3
Heterobifunctional reagent, for coupling synthetic peptides to carrier proteins, 18.3.5–18.3.6, 18.3.8–18.3.9, 18.3.15–18.3.16
Heterogeneity, of acceptor site in ligand-binding responses, A.5A.21–A.5A.23, A.5A.37
Heterologous protein expression, UNIT 5.7
Heteropolyanions, in protein precipitation, 4.5.20
Hewlett-Packard G1009 A C-terminal sequencing system
chemistry used by, 11.8.2, 11.8.5 (fig.), 11.8.5–11.8.6
HPLC in, 11.8.2, 11.8.6
results produced by, 11.8.9–11.8.12 (figs.)
sample preparation for, 11.8.1
use in automated C-terminal sequencing, 11.8.1–11.8.2, 11.8.4–11.8.13
Hewlett-Packard G1005A N-terminal sequencing system
using liquid samples, 11.10.17–11.10.19, 11.10.37
optimizing PTH amino acid separation, 11.10.21
sample cartridge, 11.10.3–11.10.4
using sequencing PVDF-bound samples, 11.10.19–11.10.21
Hexafluoropropanol (HFP), effects on buffers in capillary electrophoresis, 10.13.2–10.13.3
Hexosamines, 12.2.24
Hexoses, 12.2.24
HFP, *see* Hexafluoropropanol
HIC, *see* Hydrophobic-interaction chromatography
High-cell density methods of *E. coli* production, 5.3.8–5.3.9, 5.3.14–5.3.16, 5.3.17 (fig.)
High-mobility group (HMG) box domains, 17.1.18
High-performance anion-exchange chromatography with pulsedamperometric detection (HPAE-PAD), of radiolabeled glycoconjugates, 12.2.14
High-performance liquid chromatography (HPLC)
in amino acid analysis, 11.9.1–11.9.2, 11.9.5, 11.9.7, 11.9.30–11.9.31
for ATP quantitation, 13.8.13
in automated C-terminal sequencing, 11.8.2, 11.8.6
capillary electrophoresis and, 10.9.1, 10.9.11, 10.9.12
using hydroxylapatite
matrices for, 8.6.2 (table)
of proteins and nucleic acids, 8.6.7–8.6.8, 8.6.10
in iodination product separation, 3.3.3–3.3.4, 3.3.17
laboratory equipment required, 1.1.5
in N-terminal sequencing, 11.10.4–11.10.5 (fig.), 11.10.21–11.10.25, 11.10.36 (table)
for peptide mapping, 7.3.2–7.3.5, 7.3.17–7.3.20, 7.3.22
properties of proteins as basis for, 1.1.4
of radiolabeled glycoconjugates, 12.2.14
of recombinant proteins
analysis using SDS-PAGE and mass spectrometry, 7.10.8 (fig.)
buffers, selecting, 7.10.4
column performance evaluation, standard protein mix for, 7.10.7 (fig.)
columns, selection of, 7.10.1–7.10.3
in contamination detection, 7.1.1, 7.1.2
with diode-array detector, 7.2.10–7.2.12, 7.2.15–7.2.16
instrumentation, 7.10.3
interleukin 1β isolation, 6.2.12
membrane proteins in detergents, analysis of, 7.10.4
primary structure determination, 7.1.3
procedures for, 7.10.4–7.10.7
in solubility determination, 6.2.11
stokes radius determination, 7.10.7–7.10.10
See also Reversed-phase high-performance liquid chromatography
High-performance size-exclusion chromatography (HPSEC), 8.3.25
High-resolution SDS-PAGE, for peptide mapping, 7.3.5–7.3.6, 7.3.17–7.3.22

USC IAST / CENTRAL UNIVERSITY LIBRARY

High-throughput genomic (HTG) sequence databases, for BLASTN, TBLASTN, and TBLASTX, 2.5.4
High voltage gradients, in CZE, 10.13.15–10.13.16
HIP, *see* Hydrophobic ion pairing
his4 genotype, 5.7.3 (table), 5.7.4–5.7.9
HIS4 selectable marker, 5.7.3 (table), 5.7.5–5.7.9
"His-patch Trx," 6.7.1, 6.7.11
His tags, *see* Histidine tags
Histidine
absorption maxima and molar absorptivity, 3.1.4 (table)
as amphoteric for CZE, 10.13.3
iodination
product separation by HPLC, 3.3.8–3.3.9
reaction, 3.3.2 (fig.)
using chloramine T or iodogen, 3.3.5–3.3.6
using Iodo-Beads, 3.3.3–3.3.5
using lactoperoxidase, 3.3.6–3.3.7
labeling, strategies, 3.3.1 (table)
Histidine tags
for phage-based interaction cloning, 19.3.1
in recombinant proteins
HIV-1 integrase, 6.5.10–6.5.14, 6.5.21, 6.5.22–6.5.23, 17.3.8
ligands, 5.1.5
in purification, 6.1.4, 6.1.5 (table), 6.1.14
thioredoxin fusion proteins, 6.7.1, 6.7.11
Histidine-tail fusion proteins, MCAC of
advantages of histidine tails, 9.4.13
analysis and processing, 9.4.9
chelating groups, 9.4.13
creation of proteins, 9.4.1, 9.4.3 (fig.)
denaturing, for insoluble proteins, 9.4.6–9.4.8
native, for soluble proteins, 9.4.2–9.4.6, 9.4.13–9.4.15
NTA resin regeneration, 9.4.10
solid-phase renaturation of purified proteins, 9.4.8
Histone 2A, phosphorylation, 13.8.14–13.8.15
Histones, 17.1.20
HIV-1 integrase, *see* Human immunodeficiency virus type 1 integrase
HIV-1 and HIV-2 protease, *see* Human immunodeficiency virus type 1 and 2 proteases
^{3}H labeling
applications, 3.3.16–3.3.17
at cysteine residues using iodoacetic acid or iodoacetamide 3.3.13
at lysine or N-terminus by acetylation using anhydride, 3.3.11–3.3.12
at lysine or N-terminus by reductive alkylation, 3.3.12
in N-linked glycosylation, 12.3.5
during peptide synthesis, 3.3.14–3.3.15
strategies, 3.3.1 (table)
at tyrosine by reduction of ^{127}I-labeled peptide, 3.3.13–3.3.14
HMG (high-mobility group) box domains, 17.1.18
HOBt (1-hydroxybenzotriazole), catalyst for peptide synthesis, 18.2.13–18.2.14
Hofmeister series of anions and cations, 8.4.4–8.4.5
Homobifunctional reagents, for coupling synthetic peptides to carrier proteins, 18.3.6, 18.3.12, 18.3.16
Homogenization
devices, 4.3.18
evaluation of homogenate, 4.3.18
growth and experimental conditions of cells, 4.3.17
of mammalian cells in recombinant expression, 5.9.10
medium, 4.3.17
of tissue culture cells, 4.3.6–4.3.7, 4.3.16–4.3.17
Homology
searching, for protein identification, 16.6.6
in sequence analysis, 2.1.1
Hopp and Woods hydropathy scale, 2.2.2–2.2.3, 2.2.4 (table), 2.2.5–2.2.7, 2.2.8 (fig.)
Hormone receptor proteins, expressing domains of, 6.7.13
Hormones, density gradient centrifugation in nonionic solutes, 4.2.47
Horse
albumin protein, sequence analysis, dot plot, 2.1.4 (fig.)
myoglobin, 8.5.10 (fig.)
Horseradish peroxidase (HRPO)
in density gradient electrophoresis 4.2.30 (fig.), 4.2.48
in subcellular fractionation
cointernalization with VSV G protein, 4.3.3
determination of activity, 4.3.7
internalization as marker for endosomal compartments, 4.3.1–4.3.3, 4.3.18
Horseradish peroxidase–conjugated antibodies, 13.4.5
hpTRXFUS, 6.7.1–6.7.2, 6.7.4
HPA, in glycoprotein purification, 9.1.3 (table)
HPLC, *see* High-performance liquid chromatography
HRPO, *see* Horseradish peroxidase
hsp70, in folding of proteins, 5.9.8 (fig.), 5.9.9
Hsp82, crystallizable domains, 17.3.12
HTLE 7000, 13.3.1, 13.3.4
HTG or HTGS (High-throughput genomic sequence) database, 2.5.4
HTML, 2.4.14
Huffman coding, 10.12.7
Human antithrombin III (At-III), 5.6.3–5.6.6
Human cell lines
carboxylation of factor VIII in, 5.9.10
glycosylation in, 5.9.10
for recombinant protein production, 5.9.3 (table)
Human cytomegalovirus proteinase, 8.6.10
Human EST sequences, search using BLASTN, 2.5.17–2.5.19
Human genome, BLAST program databases, UNIT 2.5
Human Genome Project, 1.1.3
Human hemoglobin, *see* Hemoglobin
Human immunodeficiency virus type 1 integrase
generally, 6.5.10–6.5.14, 6.5.21, 6.5.22–6.5.25
protein engineering, 17.3.12–17.3.13
X-ray crystallography of, 17.3.8–17.3.13
Human immunodeficiency virus type 1 and 2 proteases, 6.3.12–6.3.15, 8.6.5 (fig. and table)
Human interleukin 2, *see* Interleukin 2
Human profilin, *see* Profilin
Human serum albumin, C-terminal sequencing of, 11.8.10 (fig.)
Human studies, sources of materials, 1.1.2
Human transferrin, *see* Transferrin
Hybridization, yeast colony, 19.2.30–19.2.31
Hybridization analysis, of DNA blots
blocking agents, alternative, A.4H.2 (table)
cloning vectors incorporating promoters for bacteriophage RNA polymerases, A.4H.6 (table)
high-salt solutions used in, A.4H.1 (table)
hybrid stability and hybridization rate, A.4H.2 (table)
probes
radiolabeled DNA, A.4H.1–A.4H.4
radiolabeled RNA, A.4H.5–A.4H.7
removal from hybridized membranes, A.4H.7
spin-column procedure for separating radioactively labeled DNA from unincorporated dNTP precursors, A.4H.8
troubleshooting guide, A.4H.3–A.4H.5 (table)
Hydrazine, 11.7.11, A.2A.16–A.2A.17
Hydrocarbon capsules, in DSC, 7.9.4
Hydrodynamic volume V_h
GF column, 8.3.21
and molecular size, 8.3.25
Hydrogen bonding, in polar residues, 2.3.1
Hydrogen peroxide, A.2A.17–A.2A.18
Hydrolase
α/β-hydrolase fold, 17.1.33, 17.1.35
hydrolase β-hexosaminidase, 4.2.30 (fig.)
Hydrolysis
of phosphoamino acids
acid, 13.3.1–13.3.5, 13.3.7
alkaline, 13.3.6, 13.3.7
in quantitative amino acid analysis, 3.2.2
of radiolabeled proteins, 12.5.8–12.5.9, 12.5.12
See also Acid digestion–ninhydrin assay
Hydrophilicity, in selecting peptide sequences for antibody production, 18.3.2–18.3.4, 18.3.14–18.3.15
Hydrophobic contaminants, removal from ion-exchange media, 8.2.24
Hydrophobic-interaction chromatography (HIC)
application, 8.4.1
buffers, 8.4.4–8.4.6
column equilibration, 8.4.17
column regeneration, cleaning, and storage, 8.4.12–8.4.15
coupled with other techniques, 8.4.17
elution of proteins
alternatives, 8.4.5
continuous-gradient, 8.4.11, 8.4.12 (fig.), 8.4.13 (fig.)
detergent, 8.4.16
polarity-reducing compounds, 8.4.16–8.4.17
salt gradient, 8.4.16
step-gradient, 8.4.12, 8.4.14 (fig.)
equipment, 8.4.4
explanations of, 8.4.15–8.4.16
flow rate, 8.4.7
hydrophobic amino acids, 8.4.1
matrix selection
composition of base matrix, 8.4.3–8.4.4
ligand type and degree of substitution, 8.4.3
parameters in, 8.4.2–8.4.3
types, 8.4.2 (fig.)
medium and packing column preparation and degassing, 8.4.6–8.4.8
packed bed testing, 8.4.8–8.4.10
pilot experiment to choose matrix and determine binding and elution conditions, 8.4.10–8.4.11
plate number and asymmetry factor, 8.4.8–8.4.9
in polybuffer removal, 8.5.8

BOSTON UNIVERSITY LIBRARY

in purification strategy, 8.1.3–8.1.4
resolution optimization, 8.4.17–8.4.20
temperature in, 8.4.5
yield, 8.1.3 (table)
Hydrophobic interactions, in aggregation, 6.4.6
Hydrophobic ion pairing (HIP), 4.5.20–4.5.21, 4.5.33
Hydrophobicity profiles
applications and procedures, 2.2.1
of hemoglobin, interleukin, and profilin, 2.3.4 (fig.)
hen egg white lysozyme, 2.2.2 (fig.)
interaction site prediction, 2.2.5–2.2.7, 2.2.10
scales in, 2.2.2–2.2.3, 2.2.4 (table)
scanning window averaging technique, 2.2.3–2.2.5, 2.2.11
secondary structure correlation, 2.2.7–2.2.8, 2.2.9 (fig.), 2.2.10
transmembrane region prediction, 2.2.9–2.2.11
Hydrophobic residues, in
secondary structure prediction, 2.3.1
sequence analysis, 2.1.13
site-specific mutagenesis, 17.3.13
Hydroxyapatite, *see* Hydroxylapatite chromatography
1-Hydroxybenzotriazole, *see* HOBt
Hydroxyethyl cellulose (HEC), used with buffers in capillary electrophoresis, 10.13.3, 10.13.5 (fig.), 10.13.8–10.13.12
Hydroxylamine
in cleavage of Asn–Gly bonds
on membranes, 11.5.5–11.5.6
in solution, 11.4.4–11.4.5, 11.4.6, 11.4.7 (table)
in hydrolysis of radiolabeled proteins, 12.5.9, 12.5.12
Hydroxylapatite chromatography
applications, 8.6.9–8.6.10
batch processing using, 8.6.6–8.6.7
binding in, 8.6.9, 8.6.11–8.6.12
column bed, 8.6.11
flow rate, 8.6.11
of HIV-2 proteinase, 8.6.5 (fig. and table)
HPLC using, 8.6.7–8.6.8
low-pressure, 8.6.1–8.6.6
matrices for, 8.6.2 (table)
using step gradient, 8.6.6
Hydroxylic matrices in ligand affinity purification, 9.3.2 (table), 9.3.10–9.3.11
Hydroxyproline
acid digestion–ninhydrin assay, 3.4.8
quantitation of, 11.9.28
N-Hydroxysuccinimidyl chloroformate, in activating matrix hydroxyl function, 9.3.2 (table)
Hyperbolic binding response, in ligand-binding theory
binding curve, A.5A.4 (fig.)
data analysis and experimental design, A.5A.8
ligand concentrations, A.5A.4–A.5A.5
ligand multivalence, A.5A.23–A.5A.26
linear transforms, A.5A.6–A.5A.8
nonlinear least-squares methods, A.5A.5
parameters defined, A.5A.4
scale, linear *versus* logarithmic, A.5A.4
sigmoidal effects
illustrative dependence, A.5A.4 (fig.)
measuring free ligand concentrations, A.5A.9–A.5A.10
reflecting ligand self-association, A.5A.15
strategy, schematic for, A.5A.9 (fig.)

elution
low-pH, 9.5.4–9.5.5
with octyl β-D-glucoside, 9.5.5
histidine tail fusion proteins in, 9.4.13
preparation of antibody-Sepharose for, 9.5.6–9.5.7, 9.5.9–9.5.10
surface features of proteins as basis for, 1.1.4
of thioredoxin fusion proteins, 6.7.12
Immunoblotting
with anti-phosphotyrosine antibodies, 13.4.1–13.4.2, 13.4.4–13.4.5
blocking agents for, 10.10.1, 10.10.7, 10.10.10
electroblotting for, membrane selection, 10.7.1, 10.7.13
IEF in, 10.2.7
immunoprobing for antigens in
with avidin-biotin coupling to secondary antibody, 10.10.2 (fig.), 10.10.3–10.10.4, 10.10.9–10.10.11
with directly conjugated secondary antibody, 10.10.1–10.10.3, 10.10.9–10.10.11
in interactor hunts, 19.2.37
membranes for, 10.10.1, 10.10.10–10.10.11
in organelle purification, 4.2.33
protein extract preparation for, 19.2.28
in protein purity, monitoring, 7.1.2
of recombinant proteins
interleukin 1β, 6.2.13
in sequence analysis, 6.1.1
recombinant vaccinia virus, expressed protein detection, 5.14.7–5.14.8
to test anti-phosphopeptide antibodies, 13.6.2
staining techniques, 10.8.6
testing for HIV-1 by, 10.10.9
visualization with
chromogenic substrates, 10.10.5 (table), 10.10.5–10.10.6
luminescent substrates, 10.10.5 (table), 10.10.6–10.10.7
Immuno-electron microscopy, 17.2.20–17.2.21
Immunogeneity, of recombinant proteins, 7.1.8–7.1.9
Immunoglobulin, 6.1.15, 8.6.9, 11.4.7 (table), 17.1.4–17.1.5
Immunogold labeling, of endosomal carrier vesicle fusion, 4.3.16
Immunoisolation
analysis of fractions, 4.3.14–4.3.16, 4.3.18–4.3.19
applications, 4.3.13
of endosomes using VSV G protein, 4.3.9–4.3.10
flotation-gradient fractionation of homogenates, 4.3.8–4.3.9, 4.3.14
homogenization of tissue culture cells, 4.3.6–4.3.7, 4.3.16–4.3.18
HRPO activity determination, 4.3.7
internalization of fluid-phase marker, 4.3.1–4.3.3
solid supports, 4.3.13–4.3.14
strategy, 4.3.1, 4.3.4 (fig.)
tissue culture cell preparation, 4.3.10
VSV G protein implantation and internalization, 4.3.3–4.3.5
Immunological assays, of recombinant proteins, 7.1.5 (table)
Immunoprecipitation
lysis of cultured cells to isolate proteins for analysis of disulfide bond formation, 14.1.7–14.1.8
measuring, kinetic considerations and equilibrium constants, 19.1.4
for phosphorylation studies
permeabilization for, 13.8.5, 13.8.7–13.8.8, 13.8.19
$^{32}P_i$ labeling and lysis for, UNIT 13.2
recombinant vaccinia virus, expressed protein detection, 5.12.8–5.12.9, 5.14.11

MALDI
for enzyme sequencing, UNIT 16.7
matrix fast-evaporation method for peptide mapping, 11.6.8–11.6.9
N-terminal sequencing and, 11.10.2, 11.10.11, 11.10.31–11.10.32, 11.10.34–11.10.36
peptide mapping, 11.6.7–11.6.8
theory and techniques, 16.1.6–16.1.10, UNIT 16.2
mass analyzers
quadrupole, 16.1.10–16.1.12, 16.1.15
time-of-flight (TOF), 16.1.7–16.1.8, UNIT 16.2
sensitivities of, compared, 16.1.3
molecular weight determination by, 16.1.8 (fig.)
MS/MS, 16.1.4–16.1.6
plasma desorption, 16.1.3
protein quantitation by, 16.1.15
of recombinant proteins
for characterization, UNIT 7.10
in contamination detection, 7.1.1
post-translational modification determination, 7.1.3, 7.1.10
primary structure determination, 7.1.3
resolution of, 16.1.19–16.1.20 (figs.)
sample preparation for, 16.1.16–16.1.17
World Wide Web sites for, 16.2.8 (table)
See also specific techniques
Mass values
changes in, from post-translational modifications, A.1A.7 (table)
of commonly occurring amino acids, A.1A.2 (table)
increments in, for carbohydrate structures, A.1A.8 (table)
of unusual and modified amino acids, A.1A.3 (table)
*MAT*α yeast strain, 5.6.2, 5.6.3–5.6.5
Matrices
for BLAST programs
BLOSUM-62, 2.5.9–2.5.10, 2.5.23–2.5.24, 2.5.28
effect on PSD analysis, 16.6.6
gel filtration, for desalting, 8.32 (table)
PAM, 2.5.23
for short sequences, 2.5.23 (table)
in chromatography, 6.1.18–6.1.19, 8.6.1, 8.6.2 (table), 8.6.10
gel-filtration, for oligosaccharides, 12.4.15
for MALDI-MS, 16.1.6, 16.2.2, 16.2.3 (fig.)
Matrix-assisted laser desorption/ionization collision-induced dissociation (MALDI-CID), sequence analysis using, 16.6.1, 16.6.4–16.6.5
Matrix-assisted laser desorption/ionization mass spectrometry (MALDI-MS)
for amino acid sequencing, UNIT 16.7
autolytic fragments in, 16.2.6 (table)
buffer compounds, tolerance for, 16.2.3 (table), 16.2.4
calibration for, 16.1.8–16.1.9, 16.2.4–16.2.5, 16.2.5 (table)
compared with other mass spectrometry techniques, 16.2.8
fingerprint mapping, in-gel digestion of proteins for, UNIT 16.4
instrument configurations for, 16.1.7 (fig.), 16.2.1–16.2.2
lasers for, 16.1.6
in mass analysis of peptides, 16.1.6–16.1.10, UNIT 16.2
matrices for, 16.1.6, 16.2.2, 16.2.3 (fig.)
matrix fast-evaporation method for peptide mapping, 11.6.8–11.6.9
mechanism of, 16.1.6
N-terminal sequencing and, 11.10.2, 11.10.11, 11.10.31–11.10.32, 11.10.34–11.10.36
peptide mapping, 11.6.7–11.6.8
peptide and protein analysis, sample preparation, UNIT 16.3
post-source decay MS for peptide sequencing, 16.1.9–16.1.10
for recombinant protein characterization
mass spectra, interpreting, 7.10.11 (table)
molecular weight standards for, 7.10.11 (table)
post-translational modifications, identifying, 7.10.12 (fig.)
procedures for, 7.10.10–7.10.12
sample preparation for, 16.1.16–16.1.17, 16.2.2–16.2.4, UNIT 16.3
spectra obtained from, 16.1.9 (fig.), 16.1.11 (fig.), 16.1.16 (fig.)
standards
molecular size, for gel filtration columns, 8.3.24 (table)
nonprotein polymer, for molecular size determination, 8.3.21
World Wide Web sites, 16.2.8 (table)
Matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF)
analysis of peptides
chemical modifications by, 16.2.7
mass analysis, 16.5.4, 16.6.5
peptide mixtures by, 16.2.5–16.2.6
synthetic peptides by, 16.2.6–16.2.7
Matrix-associated reactant, in ligand-binding theory, A.5A.15
Matrix-stacking ligand coprecipitation, 4.5.21–4.5.25, 4.5.33–4.5.34
MaxHom, 2.3.7
Maximal velocity, in ligand-binding theory, A.5A.3
Maximum limiting value, in quantitative characterization of hyperbolic response, A.5A.4–A.5A.8
MBHA resin, for α-thioester polypeptide synthesis
coupling to 3-bromopropionic acid, 18.4.9
and other resins, 18.4.2 (table)
preparation of, 18.4.9
MBP, *see* Maltose-binding protein
MBS, *see m*-Maleimidobenzoyl-*N*-hydroxysuccinimide ester
MCAC, *see* Metal-chelate affinity chromatography
2-ME, *see* 2-Mercaptoethanol
Mechanical shearing in lysis, 6.2.11
Media
bacterial growth in, APPENDIX 4B
for centrifugation, 4.1.5–4.1.7
for culturing cells for radiolabeling, 13.2.6
expression vectors, 5.11.3–5.11.5, 5.13.1–5.13.5
in gel-filtration chromatography, 6.3.10–6.3.11
gene expression using T7 RNA polymerase hybrid system, UNIT 5.15
in gradient fractionation using nonionic iodinated solutes, 4.2.20
homogenization, 4.3.17
ion-exchange, 8.2.2-8.2.8, 8.2.24-8.2.25
for mammalian cells
expression systems, 5.9.6, 5.9.10–5.9.14
general conditions, APPENDIX 3C
M9, 9.4.11
multiply deficient medium (MDM), 12.2.3–12.2.5, 12.2.8–12.2.9
in glycoconjugate labeling, 12.2.3–12.2.4
preparation and bacteriological tools, APPENDIX 4A
recombinant
characterization of, UNIT 5.14
concanavalin A-coated plates, 5.13.15
isolation of DNA, 5.13.8–5.13.9
MVA, live immunostaining, 5.13.14–5.13.15
plaques, 5.13.9–5.13.14, 5.13.17
purification process, 5.13.5–5.13.8
transfection of infected cells, 5.13.1–5.13.5, 5.13.17–5.13.18
serum-containing vs. serum-free, 5.5.16
stocks, *see* Vaccinia virus stocks
for thioredoxin expression system, 6.7.3, 6.7.4–6.7.5
transfer vectors, 5.13.4 (table)
yeast culture, 5.7.4 (table), 5.7.13, 5.7.14, 5.8.11–5.8.13
for yeast growth
liquid, A.4L.1–A.4L.2
solid, A.4L.3
See also Culture of mammalian cells
MEK protein kinase, 13.1.3
Melanoma cells, electrophoresis, 4.2.30 (fig.)
Melittin, helical wheel for amphipathic helix of, 2.3.2 (fig.)
Membrane adsorption, to desalt samples after cysteine modification, 15.1.14
Membrane proteins
analysis by electron microscopy, 17.2.9, 17.2.19–17.2.20
classification of, 1.2.1 (table)
IEF of, 10.2.7
intracellular, 1.2.2–1.2.3
purification, flow chart, 1.3.5, 1.3.6 (fig.)
in recombinant expression systems, 6.1.12
SDS-PAGE of, 6.3.13 (fig.), 10.1.31 (fig.)
secondary structure prediction, 2.3.1–2.3.2
three-dimensional structure, 17.1.44–17.1.45
Membrane-receptor interactions, in ligand binding analysis, A.5A.33–A.5A.34
Membranes
chemical cleavage on
analysis and separation of fragments, 11.5.6–11.5.7
at Asn-Gly bonds with hydroxylamine, 11.5.5–11.5.6

UCSD BIAS / CELL BIO UNIVERSITY LIBRARY

at Asp-Pro bonds with formic acid, 11.5.5
with CNBr of Edman degraded proteins, 11.5.3
at C-terminus of Met residues with CNBr, 11.5.1–11.5.2
at C-terminus of Trp residues with BNPS-skatole, 11.5.3–11.5.5, 11.5.7
cysteine reduction and alkylation, 11.5.8
sample size, 11.5.8
in contact blotting, 10.6.2
in dialysis
characteristics, 4.4.9–4.4.10
diffusion rate, 4.4.10
impurities, 4.4.10–4.4.11
in electroblotting
of chemically cleaved peptide fragments, 11.4.8
derivatized, 10.7.12
detection of proteins, UNIT 10.8
nitrocellulose, 10.7.6, 10.7.11–10.7.13
PVDF, UNIT 10.7
selection, 10.7.1, 10.7.13
enzymatic digestion on
nitrocellulose, 11.2.1, 11.2.2, 11.2.5
PVDF, UNIT 11.2
in phosphorylation studies
enhanced chemiluminescence in detection, 13.4.3
hydrolysis, 13.3.1, 13.3.6, 13.3.7
sodium carbonate fractionation
merits and limitations, 4.2.7
method, 4.2.42–4.2.43
Triton X-114 in protein extraction from, 12.5.3–12.5.4, 12.5.11, 12.5.12
in ultrafiltration
adsorption of protein to, 4.4.11–4.4.12
using asymmetric membrane disks, 4.4.4–4.4.6
centrifugal microconcentrators, 4.4.8–4.4.9
characteristics, 4.4.9–4.4.10
concentration polarization, 4.4.11
flow rates, 4.4.12 (table)
molecular-weight cutoff value, 4.4.10, 4.4.11
of recombinant proteins, 6.2.8
rejection of solute, 4.4.11
reuse of, 4.4.4–4.4.5
tangential-flow, 4.4.6–4.4.8
See also Plasma membrane purification
Membrane transport, in vitro assay of endosome fusion, 4.3.15–4.3.16
2-Mercaptoethanol (2-ME)
for cysteine reduction, 18.3.11–18.3.12
in enzymatic digestion of proteins in solution, 11.1.2 (table)
in gel electrophoresis, 10.1.3, 10.1.29–10.1.30, 13.4.5
in IEF, 10.4.25
of X-ray crystallography samples, 17.3.7, 17.3.9
3-Mercaptopropionamide-MBHA resin, for polypeptide synthesis
coupling to Boc amino acid, 18.4.11
and other resins, 18.4.2 (table)
preparation of, 18.4.11
Mercury compounds, A.2A.18–A.2A.19
MES buffer, 4.2.25
Met, *see* Methionine
Meta-search engines, WWW, 2.4.16
Metabolism, phosphorylation regulation of, 13.1.1
Metal–chelate affinity chromatography (MCAC)
of histidine-tail fusion proteins
analysis and processing, 9.4.9
chelating groups, 9.4.13
creation of proteins, 9.4.1, 9.4.3 (fig.)
denaturing, for insoluble proteins, 9.4.6–9.4.8
histidine tails, advantages of, 9.4.13–9.4.14
native, for soluble proteins, 9.4.2–9.4.6, 9.4.13–9.4.15
NTA resin regeneration, 9.4.10
solid-phase renaturation of purified proteins, 9.4.8
of HIV-1 integrase, 6.5.11–6.5.12, 6.5.22, 6.5.23
of insoluble proteins, 6.1.14
of thioredoxin fusion proteins, 6.7.12
Metal ions
in digital electrophoresis analysis, 10.12.5
in selective protein precipitation, 4.5.25–4.5.27, 4.5.34
Metallic cations, in dye affinity chromatography, 9.2.1
Metallic contaminants, removal from ion-exchange media, 8.2.24
Methanol metabolism, 5.7.1, 5.7.3
Methionine (Met)
cleavage with CNBr
on membranes, 11.5.1–11.5.2
in solution, 11.4.1–11.4.2, 11.4.5, 11.4.7
in *E. coli* expression systems, 5.1.2–5.1.3
reduction, in glycoconjugate labeling, 12.2.14, 12.3.4
[^{35}S]Methionine, in glycoprotein labeling, 12.4.6–12.4.7
Methionine aminopeptidase, 6.1.3
Methionine sulfoxide oxidation, 11.4.7
Methotrexate
amplification of DHFR in recombinant protein production in mammalian cells, 5.10.10–5.10.11
as selective pressure in mammalian expression systems, 5.9.6
α-Methyl-D-mannoside (αMM), 9.1.4–9.1.6
Methylene blue, 7.4.5–7.4.6, 7.4.8
N-Methylmercaptoacetamide, 11.4.7
N-Methylmorpholine, 13.6.7
Methyl orange, interaction with bovine serum in ligand binding, A.5A.9–A.5A.10
Methyl sulfonate, 6.1.9 (fig.)
Metrizamide
in centrifugation media, 4.1.6
in gradient fractionation using nonionic iodinated solutes, 4.2.20–4.2.22, 4.2.47
Metoprolol uptake, physical partition into hepatic microsomes, in membrane-receptor interactions, A.5A.33–A.5A.34
Mevalonic acid, 14.3.1, 14.3.3, 14.3.7 (recipe), 14.3.8
MF-α1 promoter, 5.6.2, 5.6.3–5.6.5, 5.6.6, 5.7.5
MHC peptide-binding fold, 17.1.5
Micellar SDS, in buffers for capillary electrophoresis, 10.13.14
Michaelis constant (K_m)
estimation of, 3.5.5–3.5.7
in ligand-binding theory, A.5A.3
Microbial genomes, unfinished, sequencing databases for, 2.5.1–2.5.2
Microcolumn, in purification process, 9.7.4–9.7.5
Microconcentrators, 4.4.8–4.4.9
Microfiltration
in baculovirus expression system, 5.5.11, 5.5.17
in *E. coli* fermentation, 5.3.16
Micropreparative capillary electrophoresis, 10.9.9–10.9.13
Microsomes
analysis of disulfide bond formation in, 14.1.5–14.1.7, 14.1.13, 14.1.14
centrifugation, 4.2.9
density shift using digitonin, 4.2.35–4.2.37, 4.2.38 (fig.)
dog pancreas, 14.1.5–14.1.6, 14.1.13
translocation and folding system, 14.1.5 (fig.), 14.1.13
Microtubules, depolymerization of, 4.3.10, 4.3.17
Millipore membranes, 4.4.4, 4.4.12 (table)
Milli-Q-purified water, for buffers in recombinant protein characterization, 7.10.1
Minigels
multiple gradient, 10.1.26–10.1.27, 10.1.34
silver staining, 10.5.11
single-concentration, 10.1.23–10.1.26
Minimal protein staining, in protein detection in, polyacrylamide gels, 10.6.7
Misfolded proteins, 7.1.9
Mito database for BLASTN, TBLASTN, and TBLASTX, 2.5.5
Mitochondria
centrifugation, 4.2.9
density gradient centrifugation in nonionic solutes, 4.2.47
density shift using digitonin, 4.2.38 (fig.), 4.2.48
deuterium oxide fractionation, 4.2.47
fractionation, 4.1.8 (table)
gradient fractionation using nonionic iodinated solutes, 4.2.21–4.2.22
in rat pancreas, 4.2.15 (fig.)
Mitogen-activated protein kinases (MAP), 13.5.6
Mixed-disulfide intermediates in folding, 6.4.5
αMM, *see* α-Methyl-D-mannoside
Mobility markers, in continuous nondenaturing electrophoresis 10.3.4
Mobility-shift assay, purification methods, 9.7.6–9.7.9
Modified vaccinia virus (MVA), stock preparation of, 5.12.8–5.12.9, 5.12.11
titration by immunostaining, 5.12.9–5.12.10
MOI, *see* Multiplicity of infection
Molar absorption coefficients, 3.4.9–3.4.10, 3.4.16
Molar ratio, in ligand-binding theory, A.5A.2, A.5A.29
Molecular biology techniques
absorption spectroscopy, quantitation of nucleic acids using, APPENDIX 4K
agarose gel electrophoresis, resolution of large DNA fragments on agarose gels
minigels and midigels, A.4F.2
overview, A.4F.1–A.4F.2
bacterial growth in liquid or solid media, APPENDIX 4B
DNA
digestion with restriction endonucleases, APPENDIX 4I
enzymatic amplification by PCR, APPENDIX 4J
purification and concentration from aqueous solutions, A.4E.2
media preparation and bacteriological tools, APPENDIX 4B
PCR, APPENDIX 4J
southern blotting, APPENDIX 4G
storage of, A.4C.3
Molecular mass, *see* Molecular weight

BOSTON UNIVERSITY / CENTRAL LIBRARY

Molecular replacement, in X-ray crystallography, 17.3.3
Molecular size, determination of
by GF chromatography, 8.3.4–8.3.6, 8.3.22
proteins, 8.3.17–8.3.18
Molecular weight
of amino acids
commonly occurring, A.1A.2 (table)
unusual and modified, A.1A.3 (table)
calculation, in gel electrophoresis
nondenaturing continuous, 10.3.1, 10.3.3 (fig.)
nondenaturing discontinuous, 10.3.5–10.3.7, 10.3.8 (fig.), 10.3.9
capillary electrophoresis, 10.9.12
cutoff values, of
dialysis tubing, 4.4.3
membranes in ultrafiltration, 4.4.7, 4.4.10, 4.4.11
dialysis and ultrafiltration, 4.4.10
in gel electrophoresis, as factor in
SDS-PAGE, 10.1.29–10.1.31
Tris-tricine buffer system, 10.1.9–10.1.11
measurement by electron microscopy, 17.2.3–17.2.5
of recombinant proteins, characterizing, 7.1.5
SDS-PAGE, 10.1.29–10.1.30, 10.1.33
Molecular weight standards for MALDI-MS, 7.10.11 (table)
Molscript, 2.3.18 (fig.)
Monkey cell lines, for recombinant protein production, 5.9.3 (table)
Mono P HR 5/20 column, 8.5.3, 8.5.4 (table), 8.5.5 (table)
Monoamine oxidase
density shift using digitonin, 4.2.38 (fig.)
in rat pancreas, 4.2.15 (fig.)
Monoclonal antibodies
hydroxylapatite chromatography of, 8.6.8 (fig.)
in immunoadsorption, 4.2.48
production using mammalian expression system, 5.9.4
Monolayer cultures, permeabilization, 13.8.3, 13.8.5, 13.8.6, 13.8.7
Monomeric ligands, in ligand-binding theory, A.5A.30–A.5A.32
Monomeric proteins
comparison analysis after protease cleavage, 7.10.5 (fig.)
purification, 1.2.1 (table)
Mono P HR 5/20 column, 8.5.3, 8.5.4 (table), 8.5.5 (table)
Monosaccharides
defined, 12.1.7
labeling
determining activity, 12.2.13–12.2.14
interconversion, 12.2.11, 12.2.12 (fig.)
limitations, 12.2.9
multiply deficient medium preparation and supplementation, 12.2.8–12.2.9
pulse or pulse-chase with radioactive precursors, 12.2.3–12.2.6
radioactive precursors, 12.2.13 (table)
selection of precursor, 12.2.10–12.2.11
sequential pulse or pulse-chase with reuse of medium, 12.2.6–12.2.7
specificity and final distribution, 12.2.11
steady-state with radioactive precursors, 12.2.1–12.2.3
strategy, 12.2.10 (fig.)
uptake and incorporation, 12.2.11–12.2.13
structure
conformation in solution, 12.1.4–12.1.5
diagrammatic representations of, 12.1.3–12.1.4
Fisher projections and Haworth representations, 12.1.5 (fig.)
galactose forms, 12.1.4 (fig.)
glyceraldehyde enantiomers, 12.1.3 (fig.)
stereochemistry of, 12.1.3
types of, 12.1.8
Month database
nucleotide sequence for BLASTN, TBLASTN, and TBLASTX, 2.5.4
peptide sequence for BLASTP and BLASTX, 2.5.4
Morphological analysis, of subcellular organelles, 4.3.14–4.3.15
MOSAIC (software), 2.1.14
Motifs, 2.1.12, 2.1.13 (fig.)
Mouse
antigen formation in, 5.9.9
endocrine secretion granules, gradient fractionation, using deuterium oxide, 4.2.18–4.2.19
monoclonal antibodies, 4.2.48, 8.6.8 (fig.)
MPD (2-methyl-2,4-pentanediol), 4.5.15, 4.5.31
MPEG (Moving Picture Experts Group), 10.12.7
MRC-5, for recombinant protein expression, 5.9.3 (table), 5.9.4
MS, *see* Mass spectrometry *and specific techniques*
MS-Fit, UNIT 16.5
MS-Tag, UNIT 16.6
Msc protecting group, used in polypeptide synthesis, 18.4.6–18.4.7, 18.4.15–18.4.16
Mucin, defined, 12.1.7
Multiangle low-angle light scattering (MALLS)
calibration, 7.8.6
defined, 7.8.1, in
measurement of, 7.8.3–7.8.4
molecular weight, evaluation of, 7.8.6–7.8.7
normalization, 7.8.6
radius of gyration, 7.8.7
size exclusion chromatography (SEC-MALLS)
defined, 7.8.4
experimental setup for, 7.8.5 (fig.)
molecular weight distribution, evaluation of, 7.8.7–7.8.8 (fig.)
Multipin techniques for peptide synthesis
apparatus, 18.2.2 (fig.), 18.2.3 (table), 18.2.3–18.2.5
development of, 18.2.16
ELISA, 18.2.17, 18.2.18 (fig.)
flow chart, 18.2.2 (fig.)
Fmoc-protected amino acids for, preparation, 18.2.13–18.2.14
kits, 18.2.3–18.2.5
N-terminal
acetylation of peptides, 18.2.14–18.2.15
biotinylation of peptides, 18.2.15
planning for, 18.2.3–18.2.5
procedure, 18.2.5–18.2.13, 18.2.16–18.2.17
software (Pepmaker), 18.2.5, 18.2.8–18.2.11 (figs.)
Multiple alignments in sequence analysis, 2.1.8–2.1.10
Multiple antigenic peptide (MAP), designing, 18.3.1, 18.3.7–18.3.8, 18.3.16
Multiple-angle laser light scattering (MALLS), 8.3.25
Multiple gel caster, 10.1.23–10.1.26
Multiple isomorphous replacement, in X-ray crystallography, 17.3.2
Multiplicity of infection (MOI), in baculovirus expression system, 5.5.3, 5.5.15, 5.5.16
Multiply deficient medium (MDM)
composition, 12.2.5 (table)
in glycoconjugate labeling, 12.2.3–12.2.4
preparation and supplementation, 12.2.9
stock solutions for reconstitution, 12.2.8 (table)
Multiprotein-nucleic acid complexes, crystallization of, 17.4.4
Multivalence, in ligand-binding theory, A.5A.23–A.5A.26
Multiwavelength anomalous diffraction (MAD), of recombinant proteins, 5.3.15, 17.3.3
Murine cells, *see* Mouse
Muscle movement proteins, 17.1.32–17.1.33
Mut^+ Mut^S, 5.7.2 (table), 5.7.3, 5.7.6, 5.7.14, 5.8.9, 5.8.14, 5.8.15
Mutagenesis
in recombinant protein purification, 1.2.3–1.2.4
of X-ray crystallography samples, 17.3.12–17.3.13
Mutant proteins
aggregation during protease digestion, 7.10.5
conformational analysis, 7.1.8
Mutations
circular dichroism analysis, 7.6.20 (fig.), 7.6.21
point mutations in polypeptide chains during capillary electrophoresis, 10.13.9–10.13.11
Myeloma cells, for recombinant protein expression, 5.9.3 (table), 5.9.4
Myoglobin
adsorptive losses of, 11.10.9 (table)
in chromatofocusing, 8.5.10 (fig.)
hydropathy profile, 2.2.5–2.2.7, 2.2.10 (fig.)
Myohemerythrin, electron density, 17.3.4 (fig.)
Myosin subfragment 1, 17.1.42
Myristic acid
acylation of proteins with, biochemistry of, 14.2.6–14.2.9
identification in labeled cells by TLC, 14.2.5 (fig.)
radiolabeled, in analysis of acylation, 14.2.1–14.1.3
structure of, 14.2.7 (fig.)
Myristylation, in insect cells, 5.4.3

N^{α}-blocking groups, *see* Blocking groups, N-terminal *and specific blocking groups*
N^{α}(methylsulfony)ethyloxycarbonyl-Cys, α-thioester peptide, in chemical ligation, 18.4.6–18.4.7, 18.4.15–18.4.16
N-cap, 2.3.5, 2.3.11 (table)
N-residue receptor lattice, in protein-polymer interactions, A.5A.34–A.5A.37
N-terminal cys polypeptides, synthesis of
biosynthesis methods for, 18.4.8
chemical methods for, 18.4.8
resins and amino acid derivatives for, 18.4.2 (table)
N-terminal methionine, removing, in recombinant expression systems, 6.1.3

UNLV SEVERAL UNIVERSITY LIBRARY

N-terminal residue, UNIT 16.7
N-terminal sequencing
from electroblots, 10.7.1, 10.7.5, 10.8.6
of interleukin 1β, 6.2.12
of proteins and peptides
applications, 11.10.2
using biphasic cartridge sequencer, 11.10.17–11.10.21
using Blott cartridge, 11.10.15–11.10.16
data interpretation, 11.10.25–11.10.32, 11.10.36–11.10.37
glass fiber filter supports, 11.10.12–11.10.15
instrumentation, 11.10.3–11.10.4, 11.10.5 (fig.)
vs. internal sequencing, 11.10.4, 11.10.6
liquid samples, 11.10.12–11.10.15, 11.10.17–11.10.19
log sheet for data, 11.10.2, 11.10.33 (fig.)
MALDI-MS, 11.10.11, 11.10.34–11.10.36, UNIT 16.7
order of magnitude estimate, 11.10.6–11.10.7
overview of process, 11.10.1–11.10.3
protein identification, 11.10.34–11.10.36
PTH amino acid separation optimization, 11.10.21–11.10.25, 11.10.36 (table)
PVDF-bound samples, 11.10.15–11.10.16, 11.10.19–11.10.21
sample preparation and purification, 11.10.4–11.10.11, 11.10.34, 11.10.36–11.10.37
SDS-PAGE in purification, 11.10.9–11.10.10
sequencer performance optimization, 11.10.32–11.10.34, 11.10.35 (table)
in recombinant expression systems, 6.1.4, 6.1.5 (table)
of recombinant proteins, 7.1.2, 7.1.10–7.1.11
N-terminus
in cleavage
chemical, 11.5.1–11.5.2, 11.5.4, 11.5.5
at cysteine residues with 2-nitro-5-thiocyanobenzoic acid, 11.4.6
on membranes, 11.5.6–11.5.7
labeling
carbon by acetylation using anhydride, 3.3.2 (fig.), 3.3.11–3.3.12
carbon by reductive alkylation, 3.3.2 (fig.), 3.3.12
iodination using Bolton-Hunter reagent, 3.3.2 (fig.), 3.3.9–3.3.11
strategy, 3.3.1 (table)
proteolysis in defining domain, 17.3.12
Na, K-ATPase, 4.2.34
NADH-cytochrome c reductase
density shift using digitonin, 4.2.38 (fig.)
in rat pancreas, 4.2.15 (fig.)
Namalwa cells
glycosylation in, 5.9.9–5.9.10
for recombinant protein expression, 5.9.3 (table), 5.9.4
Nanogold, for labeling in electron microscopy, 17.2.21, 17.2.22 (fig.)
National Center for Biotechnology Information (NCBI), BLAST programs, UNIT 2.5
Native chemical ligation
background and parameters, 18.4.18–18.4.20
protein synthesis, strategies for, 18.4.1–18.4.3
sequential, principle of, 18.4.7 (fig.)
of three polypeptides, sequential, 18.4.6–18.4.7
of two polypeptides, 18.4.3–18.4.6
Native proteins
folding
monitoring, 6.1.15
pathways, 6.4.1
gel electrophoresis of
continuous nondenaturing, 10.3.1
discontinuous nondenaturing, 10.3.5–10.3.7, 10.3.8 (fig.)
relative mobility, 10.3.7 (fig.)
in gel-filtration chromatography column calibration, 1.1.4
purification strategies, 1.2.3
recombinant expression systems for, 6.1.5 (table)
RP-HPLC, 6.5.8–6.5.9
stability
denaturant effects, 6.4.4
disulfide-bonded proteins, 6.4.4–6.4.5
proteolytically processed proteins, 6.4.4
sequence in, 6.4.2–6.4.4
NBRF PIR, identifier syntax for, 2.5.29 (table)
N-cap, 2.3.5, 2.3.11 (table)
NCBI
BLAST programs, UNIT 2.5
characterized, 2.1.4, 2.1.5 (fig.)
Negative dye affinity chromatography, 9.2.1, 9.2.6–9.2.7
Negative staining, preparative technique for electron microscopy, 17.2.14 (fig.), 17.2.16, 17.2.17 (fig.)
Nelson-Somogyi reducing sugar, calibration plots for spectrophotometric assays, 3.4.17 (table)
NEM, *see* *N*-ethylmaleimide (NEM)–sensitive enzyme

Permeabilization for phosphorylation studies
applications, 13.8.1–13.8.2
autoradiography in analysis, 13.8.19
using cells
for electrophoretic analysis, 13.8.6–13.8.7, 13.8.19
for immunoprecipitation analysis, 13.8.2–13.8.6, 13.8.19
direct analysis of cytosolic or membrane-bound kinases, 13.8.10
using isolated subcellular fractions
for electrophoretic analysis, 13.8.9, 13.8.19
for immunoprecipitation analysis, 13.8.7–13.8.9, 13.8.19
optimizing, 13.8.18–13.8.19
specific radioactivity of ^{32}P-containing compounds determination, 13.8.11–13.8.15
Peroxide, 4.3.7
Peroxisomes
density gradient centrifugation in nonionic solutes, 4.2.47
deuterium oxide fractionation, 4.2.47
fractionation, 4.1.8 (table)
gradient fractionation using nonionic iodinated solutes, 4.2.22
pGEX vectors
expression of GST fusion proteins using, 6.6.1–6.6.7, 6.6.19
map, 6.6.3 (fig.)
polylinker site, 6.6.4 (fig.)
pH
in capillary electrophoresis, 10.9.4–10.9.5, UNIT 10.13
in chromatofocusing, 8.5.1–8.5.3, 8.5.4 (table), 8.5.5 (table)
in Coomassie dye–binding assay, 3.4.10, 3.4.21
electroosmotic flow, effect on, 10.9.4
in electrophoresis, of phosphoamino acids, 13.3.2, 13.3.3 (fig.), 13.3.4 (fig.), 13.3.5 (fig.), 13.3.7
in folding, 6.4.5
in gel electrophoresis
IEF, 10.2.1
nondenaturing, 10.3.1, 10.3.9–10.3.10
in hydrophobic-interaction chromatography, 8.4.4–8.4.5, 8.4.16, 8.4.19
in hydroxylapatite chromatography, 8.6.4, 8.6.9, 8.6.10, 8.6.11
immunoaffinity chromatography, 9.5.4–9.5.5
in ion-exchange chromatography
and charge of protein, 8.2.1
and ion-exchange media, capacity of, 8.2.4
and ion-exchange media, selection of, 8.2.2
and microbial growth on media and columns, 8.2.24–8.2.25
range for buffers, comparison of, 8.2.3 (fig.)
range for protein binding to anion or cation exchangers, 8.2.1 (fig.), 8.2.16–8.2.18
in mammalian cell culture, 5.9.13–5.9.14
in native chemical ligation of polypeptides, 18.4.1, 18.4.3, 18.4.6, 18.4.18–18.4.19
in organelle purification
differential centrifugation by equilibrium, 4.2.11
gradient fractionation using nonionic iodinated solutes, 4.2.20
of phosphatases, 13.5.3
profiles of specific buffers for CZE, 10.13.3–10.13.5 (figs.)
in recombinant protein expression systems
inclusion body extraction, 6.3.8
ion-exchange chromatography, 6.1.10, 6.2.5
metal-chelate affinity chromatography, 6.5.12
purification, 6.2.14
in stability of proteins, 6.1.17
in ultrafiltration, 6.2.8
urea modification of proteins and, 11.10.8
UV absorption spectra, effect on, 3.4.7 (fig.), 3.4.20
pH-based step-gradient elution, 8.2.13
PHA, in glycoprotein purification, 9.1.2

BOSTON UNIVERSITY / CENTRAL LIBRARY

Phage
phage repressor, equilibrium constant example, 19.1.3
phage tail spike protein mutants, 6.4.2
recombinant, in vivo conversion into plasmid DNA, 19.3.2
Phage-based expression cloning
use of β-galactosidase protein, 19.3.1–19.3.2, 19.3.7
background and parameters, 19.3.7–19.3.8
bacteriophage cDNA library, 19.3.1, 19.3.4
cDNA expression libraries, 19.3.1
filters for bacteriophage cDNA library, preparation, 19.3.4
host strain cells, preparation, 19.3.4
^{32}P-labeled protein probe, preparation, 19.3.3–19.3.4
schematic representation, 19.3.2 (fig.)
troubleshooting guide, 19.3.8 (table)
Pharmacological agents, phosphorylation studies, 13.8.5

Phenol extraction, in DNA purification, A.4E.1
Phenolic compounds, Folin assay for, 3.4.16
Phenol–sulfuric acid neutral sugar, calibration plots for spectrophotometric assays, 3.4.17 (table)
Phenylalanine, in spectrophotometric determination of protein concentration
absorbance, 3.1.1–3.1.2, 3.1.4–3.1.6, UNIT 7.2
contribution to circular dichroism spectra, 7.6.1, 7.6.16
fluorescence emission, 3.1.3, 3.1.4–3.1.5
transitions of, electronic, 7.6.1, 7.6.16 (table)
Phenylisothiocyanate (PITC)
as blocking reagent, 11.7.8–11.7.9
in N-terminal sequence analysis, 11.10.1–11.10.2, 11.10.4–11.10.5 (fig.), 11.10.34
Phenylmethylsulfonyl fluoride (PMSF), 6.5.22, 12.5.10, A.2A.20–A.2A.21
4-Phenylspiro[furan-2 (3*H*), 1′-phthalan]-3,3′-dione *see* Fluorescamine
Phenylthiocarbamyl derivitization, 11.9.3, 11.9.4–11.9.16
Phenylthiohydantoin (PTH) amino acid analysis
using biphasic cartridge sequencer, 11.10.19, 11.10.20–11.10.21
expected recoveries of, 11.10.26, 11.10.29, 11.10.30 (table)
instrumentation, 11.10.4–11.10.5 (fig.)
using liquid samples on glass fiber filters, 11.10.14–11.10.15
optimizing separation for, 11.10.21–11.10.25
process, 11.10.1–11.10.1
using PVDF-bound samples and Blott cartridge, 11.10.16
PHO5 promoter, 5.6.2, 5.6.4 (fig.)
Phosphatase inhibitors, 13.5.2
applications, 13.1.3–13.1.4
Phosphatases
labeling studies, 13.1.1–13.1.2
in phosphorylation detection
acid phosphatase digestion, 13.5.2–13.5.3
alkaline phosphatase digestion, 13.5.3
applications, 13.5.1
^{32}P measurement and identification, 13.5.5, 13.5.6
properties of enzymes, 13.5.5–13.5.8
protein serine/threonine phosphatase digestion, 13.5.3–13.5.4
protein tyrosine phosphatase digestion, 13.5.5
strategy, 13.5.1–13.5.2
regulation of, 13.1.3–13.1.4
role of, 13.1.1
structure, 17.1.12
types of, 13.1.3
Phosphate, in hydroxylapatite chromatography, 8.6.4, 8.6.9, 8.6.10, 8.6.11
Phosphate nondenaturing polyacrylamide gels, 10.3.3 (table)
Phosphatidylinositol-specific phospholipase C, *see* Phospholipase C
Phosphoamino acids
acid hydrolysis and two-dimensional electrophoresis, 13.3.1–13.3.5, 13.3.7–13.3.8
alkali hydrolysis for Tyr- and Thr-phosphorylated proteins blotted onto filters, 13.3.6, 13.3.7–13.3.8
quantitation of, 11.9.26–11.9.27
Phosphocellulose, 6.1.10
Phosphocellulose paper, P81, 13.7.15–13.7.17, 13.7.21
Phosphoimaging, two-dimensional gel electrophoresis, 10.4.26
Phospholipase C
in cleavage of GPI-containing proteins, 12.5.5–12.5.7, 12.5.11–12.5.12
hydrophobic-interaction chromatography of, 8.4.16
Phospholipase D, 12.5.5–12.5.7, 12.5.11–12.5.12
Phosphopeptides, production of antibodies against, UNIT 13.6
Phosphoric acid, in Coomassie dye–binding assay, 3.4.21
Phosphorylase *a*, 13.1.1
Phosphorylase B, 11.10.9 (table)
Phosphorylation
dephosphorylation, inhibiting following lysis, 13.2.7
enzymatic techniques, UNIT 13.5
immunological techniques in detection of, UNIT 13.4
inhibiting following lysis, 13.2.7
kinase assays, UNIT 13.7
kinases, 13.1.3
labeling studies, 13.1.1–13.1.2
permeabiliation strategies for study of, UNIT 13.8
phosphatases, 13.1.3–13.1.4
phosphoamino acid analysis
with labeling, UNIT 13.3
without labeling, 13.1.2
^{32}Pi labeling and lysis for immunoprecipitation, UNIT 13.2
role of, 13.1.1
sites, 13.1.2
two-dimensional gel electrophoresis, 10.4.30
Phosphoryl chloride, in activating matrix hydroxyl function 9.3.2 (table)
Phosphotransferases, gel filtration of, 6.3.13
Phosphotyrosine, 13.6.8–13.6.9
Photochemical methods, for coupling synthetic peptides to carrier proteins, 18.3.6, 18.3.13
Photography, of proteins in polyacrylamide gels, 10.5.8–10.5.9
Photopolymerization catalysts, 7.4.1–7.4.2, 7.4.5, 7.4.8
o-Phthalaldehyde, in chemical cleavage on membranes, 11.5.3
Phycocyanins, 17.1.40
Phylogenetic trees, 2.1.10, 2.1.11 (fig.)

Polysialic acid, defined, 12.1.7
Polystyrene, cleaving and activating backbone for affinity matrix, 9.3.3 (table)
Polyvinylidene difluoride (PVDF) membranes
cationic-derived PVDF (CD-PVDF), 11.5.7–11.5.8
chemical cleavage on
advantages of, 11.5.7
analysis and separation of fragments, 11.5.6–11.5.7, 11.5.7–11.5.9
at Asn-Gly bonds with hydroxylamine, 11.5.5–11.5.6
at Asp-Pro bonds with formic acid, 11.5.5
with CNBr of Edman degraded proteins, 11.5.3
at C-terminus of Met residues with CNBr, 11.5.1–11.5.2
at C-terminus of Trp residues with BNPS-skatole, 11.5.4–11.5.5, 11.5.7
cysteine reduction and alkylation, 11.5.8
sample size, 11.5.8
in contact blot procedures, 10.6.2
in electroblotting
acidic extraction with organic solvents, 10.7.10, 10.7.11
detection of proteins, 10.8.1 (table), 10.8.6–10.8.7
detergents in elution from, 10.7.9–10.7.10, 10.7.11
membrane selection, 10.6.2
in semidry systems, 10.7.7–10.7.8
for sequence analysis, 10.7.5–10.7.6
with tank transfer unit, 10.7.1–10.7.5, 10.7.11
of chemically cleaved peptide fragments 11.4.8
enzymatic digestion on, UNIT 11.2
in N-terminal sequencing
using biphasic cartridge sequencer, 11.10.19–11.10.21, 11.10.37
using Blott cartridge, 11.10.15–11.10.16, 11.10.37
electroblotting and protease cleavage, 11.10.2, 11.10.9, 11.10.34
estimating amount of protein, 11.10.10–11.10.11
phosphoamino acid analysis on
acid hydrolysis, 13.3.1, 13.3.7
alkaline hydrolysis, 13.3.6, 13.3.7
in quantitative amino acid analysis, 3.2.2
sample cleanup filters, in cysteine reduction and alkylation, 11.4.7
Polyvinylpyrrolidone, in centrifugation media, 4.1.6–4.1.7
Polyvinylpyrrolidone-coated colloidal silica, *see* Percoll
Ponceau S
blot transfer membrane staining, 10.8.3
sensitivity and membrane compatibilities, 10.8.1 (table)
Porcine growth hormone, 6.5.18–6.5.19
Pore size matrix, 8.3.6
Pore volume, GF chromatography
and bed volume, 8.3.25–8.3.26
for protein fractionation, 8.3.27
Positive dye affinity chromatography
batch elution, using, 9.2.7–9.2.8
gradient elution, using, 9.2.8–9.2.9
process, 9.2.1
Positive plaques, for protein identification, 19.3.8 (table)
Post-mitochondrial supernatant, of rat liver lysosomes, 4.3.15
Postnuclear supernatant (PNS)
flotation-gradient fractionation of, 4.3.8–4.3.9, 4.3.14
homogenization and centrifugation in preparation, 4.3.6–4.3.7
purification in organelle fractionation, 4.2.9, 4.2.12, 4.2.15 (fig.) 4.2.32, 4.2.41
Post-source decay (PSD) mass spectra
of metastable ions by laser pulses, 16.3.1
for partial peptide sequencing, 16.4.2
protein identification using, 16.6.1
tryptic peptide spectrum, 16.6.2 (fig.)
Post-transitional modifications in proteins, identified using MALDI-MS, 7.10.12 (fig.)
Post-translational folding
analysis of, 14.1.1, 14.1.4, 14.1.7
detection through charge heterogeneity, 7.3.2, 7.3.13–7.3.15
Post-translational modifications
expression systems for, 7.1.1
mass changes due to, A.1A.7 (table)
prenylation and carboxyl-methylation, UNIT 14.3
of recombinant proteins
characterizing, 7.1.3
in mammalian expression systems, 5.9.1, 5.9.9–5.9.10, 5.9.12–5.9.13
See also Glycosylation *and* Phosphorylation
Potassium dichromate, as marker in gel-filtration chromatography, of recombinant proteins, 6.2.8
Potassium hydroxide
in detection of phosphorylated proteins 13.3.6, 13.3.7
in hydrolysis of radiolabeled proteins, 12.5.8–12.5.9
Potassium phosphate, 4.4.10
Potato acid phosphatase, in phosphorylation detection, 13.5.2–13.5.3, 13.5.6
Poxviridae, 5.11.1
prB1 genotype, 5.7.3 (table), 5.7.4
Precast gels, in SDS-PAGE, 10.1.9 (table), 10.1.29
Precipitated material contaminants, removal from ion-exchange media, 8.2.24
Precipitation
using ammonium sulfate, APPENDIX 3F
in desalting, 4.4.12
in polybuffer removal, 8.5.8
of recombinant interleukin 1β, 6.2.12
of recombinant proteins, 6.1.10
interleukin 1β, 6.2.8
selective
choice of procedure, 4.5.1 (table), 4.5.4
clarification of protein solutions in preparation for, 4.5.2
concentration of samples in preparation for, 4.5.2
heteropolyanions, 4.5.20, 4.5.32–4.5.33
hydrophobic ion pairing, 4.5.20–4.5.21
isoionic precipitation, 4.5.9–4.5.12, 4.5.29
matrix-stacking ligand coprecipitation, 4.5.21–4.5.25, 4.5.33–4.5.34
metal ions, 4.5.25–4.5.27, 4.5.34
neutral polymers and osmolytes, 4.5.15–4.5.16, 4.5.30–4.5.32
nucleic acids, removal in preparation for, 4.5.4–4.5.5
organic cosolvents, 4.5.13–4.5.15, 4.5.29–4.5.30
pilot experiments for, 4.5.3–4.5.4
polyelectrolytes, 4.5.16–4.5.19
salting out, 4.5.5–4.5.8, 4.5.28–4.5.29
in X-ray crystallography sample preparation, 17.3.8
Prenylation
biochemistry of, 14.3.8–14.3.9
groups used in post-translational modification by, 14.3.8 (fig.)
labeling of cultured cells for analysis of, 14.3.1–14.3.2, 14.3.9–14.3.10
mevalonic acid as precursor for, 14.3.1, 14.3.3, 14.3.7 (recipe), 14.3.8
of proteins during in vitro translation, 14.3.3–14.3.4, 14.3.9–14.3.10
relationship to carboxy-methylation, 14.3.1, 14.3.4, 14.3.8–14.3.9
Preferential binding to acceptors, in ligand-binding theory, A.5A.27–A.5A.29
Prepacked columns, characterized for size-exclusion protein fractionation, 7.10.2 (table)

BOSTON UNIVERSITY / CENTRAL LIBRARY

Pressure drop, GF column, 8.31
PRF (Protein Research Foundation), 2.5.3, 2.5.29 (table)
Primary structure, *see* Sequence analysis
Primers, for cDNA synthesis, 19.3.1
Probes, hybridization
  preparation of, A.4H.1-A.4H.7
  removal from membrane, A.4H.7
ProBlott, enzymatic digestion on, 11.2.8, 11.2.8 (fig.), 11.2.9 (fig.)
"Process" enzymes, 1.1.1
Profile analysis method, 2.1.12
PROFILESEARCH (software), 2.1.12, 2.1.13
Profilin, secondary structure prediction
  Chou and Fasman method, 2.3.4 (fig.), 2.3.9 (fig.), 2.3.10 (fig.)
  comparison of methods, 2.3.11–2.3.18, 2.3.13–2.3 18
  Protein Sequence Analysis method, 2.3.16 (fig.)
Prolactin, hydrophobic-interaction chromatography of, 8.4.17
Proline
  in acid digestion–ninhydrin assay, 3.4.8
  as α helix initiator, 2.3.5, 2.3.11 (table)
  for mammalian cell culture, 5.9.11
  prolyl isomerase in conformation, 1.3.2–1.3.3
Proline–aspartic acid bonds (Pro-Asp), cleavage with formic acid
  on membranes, 11.5.5–11.5.6
  in solution, 11.4.4, 11.4.7 (table)
Prolyl isomerase, proline in conformation, 1.3.2–1.3.3
Promoters
  in *E. coli* expression systems
    characteristics of systems, 5.1.2, 5.2.1, 5.2.2 (table)
    in fermentation, 5.3.6
    lac/tac, 5.2.2 (table), 5.2.4, 5.2.14–5.2.16
    pL, 5.2.2–5.2.3
    T7 RNA polymerase, 5.2.2 (table), 5.2.5, 5.2.6, 5.2.15
    trp, 5.2.2 (table), 5.2.3–5.2.4, 5.2.15
  GAL1, 19.2.35
  for mammalian cell expression systems, 5.9.4, 5.9.12
  in *S. cerevisiae* expression system, 5.6.1 (table), 5.6.2
  in thioredoxin gene fusion expression vectors, 6.7.2
Propidium iodide
  detection, A.2A.15
  disposal, A.2A.13
PROPSEARCH, WWW site for amino acid analysis, 11.9.28, 11.9.35–11.9.36
PROSITE database, 2.1.12–2.1.14
Protease inhibitors
  generally, 6.1.7, 6.1.10, 11.1.3
  for lysates in permeabilization, 13.8.5
  in serum, 5.9.11–5.9.12
Proteases
  to cleave proteins
    in gels, UNIT 11.3
    in solution, UNIT 11.1
    on PVDF membranes, UNIT 11.2
  in enzymatic digestion of histidine tags, 6.5.13, 6.5.22–6.5.23
  in fusion protein cleavage, 5.1.6
  hydroxylapatite chromatography of, 8.6.5 (fig. and table)
  mutant protein aggregation during digestion, 7.10.5 (fig.)
  in peptide mapping, 7.1.10
  in phosphorylation studies, 13.5.7
  $^{32}P_i$ labeling, 13.1.2
  recombinant, gel filtration in guanidine hydrochloride, 6.3.12–6.3.15, 6.3.21
  in *S. cerevisiae* expression system, 5.6.6
  in SDS-PAGE, 10.1.7, 10.1.33
  structure, 17.1.35–17.1.38
  for tag removal, 17.3.8
Protease sensitivity, of recombinant proteins, 7.1.4 (table)
Proteasome, 17.1.43
Protective equipment for handling hazardous chemicals, A.2A.3
Protein A, as molecular weight standard for MALDI-MS, 7.10.11 (table)
Protein A–Sepharose beads, in immunoprecipitation of proteins, 14.1.7–14.1.8
Protein capacity, of ion-exchange media, 8.2.4–8.2.5 (table)
Protein class, Chou and Fasman method of predicting, 2.3.3–2.3.4
Protein composition, of subcellular compartments, 4.3.14
Protein Data Bank (PDB), 2.3.3, 2.5.3, 17.1.3–17.1.4
Protein disulfide isomerase
  in folding, 5.9.8 (fig.), 5.9.9
  generally, 6.4.2
Protein engineering, for X-ray crystallography samples, 17.3.11–17.3.13
Protein-exclusion agents, in protein precipitation, 4.5.15–4.5.16, 4.5.30–4.5.32
Protein extract, small-scale preparation, 5.8.10–5.8.11
Protein fractionation
  in GF chromatography
    buffer preparation, 8.3.22
    discussed, 8.3.14–8.3.17
    matrix selection criteria, 8.3.2–8.3.4
    optimization and scaleup, 8.3.26
  for recombinant protein characterization, 7.10.1–7.10.3
Protein fragments, for native chemical ligation, UNIT 18.4
Protein identification
  comparisons, with BLASTN, 2.5.18–2.5.19
  by interaction cloning, UNIT 19.3
  PIR database, 2.5.3
  positive plaques and troubleshooting, 19.3.8 (table)
Protein kinase A (PKA) recognition, 19.3.1
Protein kinase C (PKC) isoforms, assay for, 13.7.6–13.7.7
Protein kinases, *see* Kinases *and individual enzymes*
Protein-nucleic acid complexes, crystallization of, 17.4.3–17.4.4, 17.4.8–17.4.9 (table)
Protein-polymer interactions, in ligand binding analysis, A.5A.34–A.5A.37
Protein probes, autophosphorylation with ^{32}P, 19.3.7
Protein-protein
  complexes, crystallization of, 17.4.3–17.4.4
  interactions, screening with interaction trap procedure, 19.2.17
Protein purification
  for biosynthesis of polypeptides, 18.4.8, 18.4.15
  for native chemical ligation HPLC analysis, 18.4.5
  for phage-based expression cloning, 19.3.1, 19.3.7
Protein Research Foundation (PRF), 2.5.3, 2.5.29 (table)
Protein separation
  in acidic isoelectric buffers, 10.13.7–10.13.9
  ion-exchange chromatography, UNIT 8.2
Protein Sequence Analysis (PSA) method of secondary structure prediction
  applying, 2.3.8–2.3.9
  basis of, 2.3.7
  comparison with other methods, 2.3.11–2.3.18
  in glycoprotein purification, 9.1.2 (table)
  Internet location, 2.3.13 (table)
Protein sequence databases, use of
  BLAST, UNIT 2.5
  NCBI databases, 2.5.3–2.5.4
  programs compared, 2.5.2, 2.5.3 (table)

Raney nickel, 11.4.6
Rapid evaporation method, sample preparation for MALDI-MS, 16.3.1, 16.3.2–16.3.
Rat
albumin protein, sequence analysis, dot plot, 2.1.4 (fig.)
exocrine tissue, gradient fractionation using Percoll, 4.2.14–4.2.17
liver
density shift using digitonin, 4.2.35–4.2.37, 4.2.38 (fig.), 4.2.48
differential centrifugation by equilibrium, 4.2.9–4.2.11
differential centrifugation by velocity, 4.2.7–4.2.9
electrophoresis, 4.2.24–4.2.29, 4.2.30 (fig.), 4.2.47
gradient fractionation using nonionic iodinated solutes, 4.2.20–4.2.22
solid-phase immunoadsorption of, 4.2.30–4.2.33
subcellular fractionation, 4.3.15
pancreas, rate zonal centrifugation using sucrose, 4.2.12–4.2.14, 4.2.15 (fig.)
Rayleigh band, in fluorescence spectra, 7.7.3 (fig.), 7.7.11
RCA, in glycoprotein purification, 9.1.2 (table), 9.1.9
Reactive dyes
commercially available, 9.2.12 (table)
immobilization of, 9.2.10–9.2.13
structures of, 9.2.11 (fig.)
See also Dye affinity chromatography
Reagents and solutions (recipes)
Ac_2O/DIEA/DMF solution, 18.4.16
acetate buffer (pH 3.5), 0.1 M, 12.5.9
acetic acid-native gel buffer, 4×, 10.3.8
acetylation solution, 18.2.15
acid/ethanol cleaning solution, 7.2.13
acid protein sample buffer, 7.4.5
acrylamide/bisacrylamide stock solution
for titration-curve analysis, 7.3.15
for urea-gradient electrophoresis, 7.4.5
acrylamide 30%/bisacrylamide 0.8%, 10.4.27
AcSH/DIEA/DMF solution, 18.4.16
agarose, 10.4.27
agarose in reducing buffer, 10.4.27
alkaline phosphatase substrate buffer, 10.10.7
alkylating agent, 15.1.15
alkylation buffer, 7.3.15
αMEM medium, 5.10.27
ammoniacal silver nitrate solution, 10.5.9–10.5.10
ammonium acetate, 10 M, A.2E.1
ammonium persulfate, 10.4.27
ammonium persulfate, 10%, 7.3.16
ampicillin, 5 mg/ml, 6.6.17
anhydrous solvents, 9.3.8
anion-exchange buffer, 6.2.9
anode buffer, 10.1.27

Reagents and Solutions (continued)

antibiotic stock solutions (1000×), 5.2.12
[γ-^{32}P]ATP solution, 13.7.18
avidin buffer, 3.6.10
basal salts solution, 5.8.11
basic protein sample buffer, 7.4.5
BCA reagents, 3.4.13–3.4.14
binding buffer (BB), 19.3.6
biotin-cellulose binding buffer, 9.7.9
biotin-cellulose elution buffer, 9.7.9–9.7.10
biuret reagent, 3.4.14
blocking buffers, for colorimetric and luminescent immunoblot detection, 10.10.7
BME/DIEA/DMF solution, 18.4.17
bovine growth hormone
break buffers, 6.5.14
column buffers, 6.5.15
extraction buffer, 6.5.15
folding buffers, 6.5.15–6.5.16
wash buffer, 6.5.16
3-bromopropylamine, 15.1.15
BSSM fermenter medium, 5.8.11
buffer TM, 9.6.11
buffer Z, 9.6.11
buffer Ze, 9.6.12
CAA/glycerol/ampicillin 100 medium, 6.7.9
CaM kinase reaction buffer, 13.7.18
calibration standards, 8.3.22
cA-PrK assay buffer, 13.8.16
carbonate developing solution, 10.5.10
Casamino acids, 5.8.11, 6.7.9
β-casein digestion, 10.13.11
casein kinase reaction buffer, 13.7.18
cathode buffer, 10.1.27
cation-exchange buffer, 10×, 6.2.9
chase medium, 14.1.9
cell lysis buffer, 5.14.9
chromogenic visualization solutions, 10.10.8
cleavage buffer, 18.4.17
CNBr, 9.3.7–9.3.8
CNBr in formic acid, 11.4.4–11.4.5
CNBr/acetonitrile, 9.5.8
cold ATP stock solution, 13.8.16
column buffers, 9.1.8, 18.4.17
column regeneration buffer, 9.6.12
column storage buffer, 9.6.12
column storage solutions, 9.5.8
commonly used buffers and stock solutions, A.2E.1–A.2E.5
complete DMEM-10 or -20, 5.12.10
complete MEM-2.5, -10, or -20, 5.12.11
complete MEM-10/BrdU or -20/BrdU, 5.12.11
complete spinner medium-5, 5.12.11
complete 2× plaque medium-5, 5.13.16
Coomassie blue staining solution
G-250, 10.1.27
acid-based, 10.5.9
R-250 for fixing and staining in PAGE gels, 10.5.10
R-250 for staining in urea gels, 7.4.5
Coomassie dye reagent, 3.4.14
coupling buffer, 3.6.11
cyanide detection reagent, A.2A.24
cyanogen bromide, 2 mg/ml in 70% formic acid, 7.3.16
cyclic nucleotide–dependent protein kinase reaction buffer, 13.7.18
cycloheximide, 14.1.10
cysteine, 1 M, 14.1.10
cysteine standard stock solution, 15.1.15, 18.3.14
Denhardt solution, A.4H.9
DEPC treatment of solutions and labware, 14.1.10
depletion medium, 14.1.10

Reagents and Solutions (continued)

detector flow cell, 11.6.10
detergent lysis buffer, 5.5.14
detergent stock solutions, 9.5.8
dialysis tubing, pretreated, 7.3.16
digestion buffer, for peptide mapping, 7.3.16
digestion buffer, for PVDF-bound proteins, 11.2.4
digitonin density shift gradient stock solutions, 4.2.43
digitonin stock solution (20 mg/ml), 4.2.43
diisopropylfluorophosphate (DFP) solution, 1%, 11.2.4
dioxetane phosphate substrate buffer, 10.10.8
dithiothreitol (DTT), 1 M, A.2E.1
DLM medium, 5.3.12
DMEM, complete, A.3C.11
DMEM/F12 custom-modified medium, 5.10.27
DMSO/PPO solution, 10.2.6
DNA extraction buffer, 5.14.9
DNase and RNase solution, 10.4.27
DNase I solution, 9.4.11
DryStrip equilibration solutions, 10.4.27
ECPM1 medium, 5.3.13
EDTA (ethylenediamine tetraacetic acid), 0.5 M (pH 8.0), A.2E.1
EDTA, 200 mM, 14.1.10
EDTA, 2%, 10.4.28
electrode solutions, 7.3.17
electrophoresis buffer
pH 1.9, 13.3.6
pH 3.5, 13.3.6–13.3.7
for urea-gradient gels, 7.4.5
Ellman's reagent solution, 18.3.14
endo H digestion buffer, 12.3.7
enzyme solutions
clostripain, 11.2.5
endoproteinases, 11.2.4–11.2.5
trypsin, 11.2.4
equilibration buffer, 10.4.28
ethanolamine hydrochloride, 9.6.12
ethidium bromide, 10 mg/ml, A.2E.1
N-ethylmaleimide (NEM), 14.1.11
extracellular buffer, 13.8.16
extraction buffer, 6.3.7
extraction solution (40% acetonitrile/1% trifluoroacetic acid), 10.7.11
Farmers reducer, 10.5.10
fast-evaporation MALDI solution, 11.6.10
FBS (fetal bovine serum), A.3C.11–A.3C.12
formaldehyde fixing solution, 10.5.10
formamide loading buffer, 9.6.12
gel-filtration buffers, 6.2.10, 6.3.7, 8.3.22–8.3.23, 7.10.12
gel-filtration chromatography, columns, for separating released oligosaccharides, 12.4.12
glass beads, acid washed, 5.8.11
gliadin extraction, 10.13.12
globin chain preparation, 10.13.12–10.13.13
L-glutamine, 0.2 M, A.3C.12
glutaraldehyde solution, 18.3.14
glutathione
buffer, 6.6.17
stock solutions, 0.1 M, 6.5.16
glycerol solution, 19.2.33
glycine buffer, for immunoaffinity chromatography, 9.5.8
glycine gel buffer, 4×, 10.3.8
GPI-PLD buffer, 12.5.9
guanidine·HCl, 18.3.14
guanidine·HCL buffer, 6 M, 18.4.17
GuMCAC buffers, 9.4.11
GuMCAC-EDTA buffer, 9.4.11
Hanks' balanced salt solution (HBSS), A.3C.12

RUTGERS / CENTRAL UNIVERSITY LIBRARY

Hartree-Lowry reagents, 3.4.14
HCDF1 medium, 5.3.13
HCDM1 medium, 5.3.14
HCl, 1 M, A.2E.2
HEPES, 14.1.10
HEPES blocking buffer (HBB), 19.3.6
HF/p-cresol solution, 18.4.17
holmium oxide reference solution, 7.2.13
homogenization buffer, 4.3.10, 5.10.28
homogenization medium (lectin adsorption), 4.2.44
homogenization medium (velocity differential centrifugation) 4.2.44
horseradish peroxidase, A.2A.24
HPLC solvents, 7.3.17
HRPO substrate solution, 4.3.11
hydrazine detection reagent, A.2A.24
hydroxylamine·HCl (pH 7.5), 1 M, 12.5.10
hydroxylamine solution, 11.4.5, 11.5.7
hyperosmotic buffer, 4.2.44
hyperosmotic homogenization medium (colloidal gold density shift), 4.2.43
IEF solubilization buffer, 10.2.6
IMC medium, 6.7.9
IMC plates, 6.7.9
immunoprecipitate wash buffer for boiled sample, 13.2.5
immunoprecipitation wash buffer for analysis of disulfidebond formation, 14.1.11
indole-3-acrylic acid, 5.2.13
inducer stock solutions, 5.2.13
inhibitor stock solutions, 12.3.7
for interactor hunts, 19.2.33
interleukin
  break buffers, 6.5.16
  extraction buffer, 6.5.18
  folding buffer, 6.5.18
internalization medium, 4.3.11
intracellular buffer, 13.8.16
isopropyl-1-thio-β-D-galactopyranoside (IPTG), 5.2.13, 6.6.17
KCl, 1 M, A.2E.2
Laemmli buffers, 19.2.33
LB medium, 5.2.13
leupeptin, 10.4.28
linker-kinase buffer, 9.6.12
loading buffer, 10×, 9.7.10
low-salt buffer, 5.14.10
luminescent visualization solutions, 10.10.8
lyophilization buffer (25 mM sodium phosphate, pH 7.5/0.5 mM sodium azide), 6.2.10
lysis buffer
  for analysis of disulfide bond formation, 14.1.11
  for extraction of insoluble *E. coli* proteins, 6.3.7
  for immunoaffinity purification, 9.5.8
  for immunoprecipitation, 13.8.16
  for inhibition of N-linked glycosylation, 12.3.7
  for kinase assays, 13.7.18
  for polypeptide synthesis, 18.4.17
  for preparation of soluble *E. coli* proteins, 6.2.10
  for preparing soluble GST fusion protein, 6.6.18
  two-dimensional gel electrophoresis, 10.4.28
lysis solution, 19.2.33
M9 medium, 9.4.11
M9 salts, 6.7.10
Mg/ATP solution, 13.7.19
MALDI matrix solution, 11.6.10
for MALDI-MS of peptides and proteins, 16.3.5
mass standard solution, 11.6.11
matrix solution, saturated, 7.10.12

MCAC buffers, 9.4.12
MCAC-EDTA buffer, 9.4.12
media for yeast growth and manipulation, A.4L.1–A.4L.3
methionine, 14.1.11
mevalonic acid, 100 mM, 14.3.7
mevinolin, 10 mM, 14.3.7–14.3.8
7.4 M medium, 4.3.10
M9 medium, 9.4.11
$MgCl_2$, 1 M, A.2E.2
$MgSO_4$, 1 M, A.2E.2
mild lysis buffer, 13.2.5
M9 minimal medium, 5.2.13
modification mixture, 11.9.28
multiply deficient medium, 12.2.8–12.2.9
M9ZB medium, 9.4.11
NaCl, 5 M, A.2E.2, A.2E.3 (table)
NaOH, 10 M, A.2E.2
NED solution, 11.7.11
ninhydrin, 3.4.15
nutrient supplements for YNB medium, 5.8.13 (table)
orthophosphoric acid (H_3PO_4), 10.4.28
oxidizer, 10× and 1×, 10.5.10
PBS, 10.4.28, 13.2.5, A.2E.3
PBS/BSA, 13.8.16, 13.2.5, A.2E.3
PBS/EDTA, 6.6.18
PBS/EDTA/PMSF buffer, 6.6.18
PBS/glycerol buffer, 6.6.18
PBS with proteolysis inhibitors, 10.4.29
PBS/Tween, 5.14.10
pepstatin, 10.4.29
peptide matrix/nitrocellulose solution, 16.3.5
Percoll gradient stock solutions, 4.2.44
permeabilization buffer, 13.8.17
PGA digestion buffer, 11.7.11
PGA-N substrate, 11.7.2
phenol, buffered, A.2E.2
phosphate buffer, A.2A.24
phosphate gel buffer, 4×, 10.3.8
phosphate/SDS, pH 7.2, 10.1.13
phosphate/SDS sample buffer, 2×, 10.1.29
phosphoamino acid standards mixture, 13.3.7
physiological buffer, pH 7.4, 3.6.11
piperidine/DMF, 18.2.15
PI-PLC buffer (for *B. thuringiensis* enzyme), 12.5.10
PKA buffer, 10×, 19.3.6
PKC reaction buffer, 13.7.19
plates, 5.2.14
plug solution, 10.1.28
PMSF, 14.1.12
polyacrylamide gels
  acetic acid nondenaturing, 10.3.2 (table)
  acrylamide/bisacrylamide
  30%/0.8%, 10.1.5
  30%/1.6%, 10.2.6
  glycine nondenaturing, 10.3.5 (table)
  heavy acrylamide solutions, for gradient gels, 10.1.19, 10.1.23
  light acrylamide solutions, for gradient gels, 10.1.19, 10.1.22
  modified Laemmli peptide separating and stacking gels, 10.1.12
  multiple single-concentration, 10.1.16
  phosphate nondenaturing, 10.3.3
  separating and stacking, 10.1.5
  tricine peptide separation and stacking gels, 10.1.10
  Tris nondenaturing, 10.3.4 (table)
polyacrylmide-urea gel, 16%, 9.6.13
potassium acetate buffer, 0.1 M, A.2E.3
potassium phosphate buffer, 0.1 M, A.2E.4

protease inhibitor cocktail
  for MCAC, 9.4.12
  for subcellular fractionation, 4.3.11
  for yeast, 5.8.12
protease inhibitor mix, 5.5.13
protease inhibitor stock solutions, for kinase assays, 13.7.19
proteinase inhibitor cocktail, 4.2.44
protein extraction buffer, 5.8.12
PTM_1 salt solution, 5.8.12
radioactive ink, 14.3.8
rate zonal centrifugation gradient stock solutions, 4.2.45
reducing buffer, 10.4.29
reduction/acylation cocktail, 15.1.15
resuspension buffer, 5.10.28
RIPA correction buffer, 13.2.5
RIPA lysis buffer, 13.2.5–13.2.6
RP-HPLC solvents, 6.5.18
RPMI, complete, A.3C.11
running buffer, 4.2.45
salmon sperm DNA, 19..2.28–19.2.29, A.4H.7
sample buffer, nonreducing, 14.1.12
saturated matrix solution, 7.10.12
SDS
  10%, 10.1.12
  electrophoresis buffer, 5×, 10.1.27–10.1.28
  lysis buffer, 13.2.6
  recrystallized, 10.1.28
  sample buffer, 10.1.28, 10.1.29
SDS, 20%, A.2E.4
SDS-PAGE sample buffer, 6.7.10, 13.8.17
side chain deprotecting solution, 18.2.16
small peptide mixture, 14.1.12
SOC medium, 5.2.14
sodium acetate, 3 M, A.2E.4
sodium acetate buffer, 0.1 M, A.2E.4
sodium phosphate buffer, 9.5.8
sodium phosphate buffer, 0.1 M, A.2E.4
sodium sulfite reagent buffer, 15.1.15
sonication buffer, 18.2.16
SSC (sodium chloride/sodium citrate) 20×, A.2E.4
standard protein solution, 3 mg/ml, 3.1.3
stop buffer, 14.1.12
for storage and retrieval of yeast stocks, A.4L.3–A.4L.4
streptolysin O solutions, 13.8.17
sucrose solutions, 4.3.11–4.3.12
sulfanilic acid solution, A.2A.24
suspension medium (SM), 19.3.6
synthetic peptide substrate solution, 13.7.19
TAE (Tris/acetate/EDTA) electrophoresis buffer, A.2E.4
TBE electrophoresis buffer, pH 8.1, A.2A.25
TBE (tris/borate/EDTA) electrophoresis buffer, 9.6.13, A.2E.4
TBS, 12.5.10
TE buffer, A.2E.4
T4 polynucleotide kinase buffer, 9.6.13
thiosulfate developing solution, 10.5.10
thrombin, 2000 NIH units/ml, 6.5.18
trace element solutions 1 & 2, 5.3.14
transfection buffer, 5.13.16
transfer buffer, 10.6.6
  20×, 10.7.11
tricine sample buffer, 2×, 10.1.29
triethanolamine solution, 9.5.8
Tris-buffered saline (TBS)
  for immunoblot detection, 10.10.9
  for immunoprecipitation of adherent cells, 13.2.6
  for phosphoamino acid analysis, 13.3.7
  with Triton X-100 (TBS-T), 19.3.6

UCI MEDICAL CENTER LIBRARY

Reagents and Solutions (continued)
Tris·Cl
pH 6.8, 4×, 10.1.12
pH 8.8, 8×, 10.1.12
Tris·Cl/SDS
pH 6.8, 4×, 10.1.5
pH 8.45, 10.1.10
pH 8.8, 4×, 10.1.5
Tris gel buffer, 4×, 10.3.9
Tris/glycerol solubilization buffer, 2×, 10.3.9
Tris/glycine electrophoresis buffer, 10.3.9
Tris/guanidine buffer, 15.1.16
Tris/saline/azide (TSA) solution, 9.5.9, 12.3.7
Tris/SDS buffer, 10.4.29
Tris/Triton/NaCl buffer, 9.5.9
Triton/SDS buffer, 10.7.11
Triton X–100 solution, 20%, 10.4.29

Reducing conditions for endoproteinase digestion, 11.1.2 (table)
Reducing SDS-PAGE, 14.1.8–14.1.9, 14.1.14
Reducing sugar, defined, 12.1.7
Reductants, in storage of recombinant proteins, 6.1.16
Reduction
of cysteine residues, 11.4.6–11.4.7, 11.5.8
in digest mixtures, 11.1.10
of SDS-PAGE–separated proteins, 11.3.7
Reductive alkylation
in lysine labeling, 3.3.2 (fig.), 3.3.12
See also Reductive methylation
Reductive methylation, modification of amino groups by
chemistry of, 15.2.12 (fig.)
method, 15.2.11–15.2.13
vs. reductive alkylation, 15.2.12
Refolding of proteins, *see* Folding of proteins
Refractive index
of aqueous sucrose solutions, 4.1.5 (table), 4.2.17
in gradient fractionation using nonionic iodinated solutes, 4.2.21
Refractometers, purpose of, 4.1.3
Rel transcription factors, 17.1.19
Relative centrifugal force (RCF), 4.1.2, A.2C.1, A.2C.2–A.2C.3 (fig.)
Relative mobility, in molecular weight calculations, 10.3.5, 10.3.7 (fig.), 10.3.8 (fig.), 10.3.9
Relative specific activity, defined, 4.3.15
Relaxed control in plasmid replication, 5.1.1
Renin, in fusion protein cleavage, 5.1.6
Repetitive yield, 11.10.26–11.10.27
Replica plating, isolating single colonies, A.4B.3
Replication
in baculovirus expression system, 5.4.1, 5.4.2 (fig.)
in *E. coli* expression systems, 5.1.1
enzymes in, 17.1.29–17.1.32
vaccinia virus, 5.11.1–5.11.2
Reporter genes
lacZ, 19.2.3, 19.2.35
LEU2
for bait protein analysis, 19.2.3
for interactor hunts, 19.2.23
Repression assay, fusion-protein synthesis confirmation by, 19.2.10
Reproducibility of methods, protein purification/RP-HPLC 1.1.2
Resins
used in polypeptide synthesis, 18.4.2 (table), 18.4.10–18.4.11
in prepacked columns for size-exclusion chromatography, 7.10.2 (table)
Resistance genes, *see* Drug resistance genes
Resolution
in chromatography
capacity, 8.1.6–8.1.7
determining, 8.1.5–8.1.7
efficiency, 8.1.7–8.1.8, 8.1.9 (fig.)
equation for, 8.3.26–8.3.27
GF, 8.3.2
hydrophobic interaction, 8.4.12 (fig.), 8.4.13 (fig.), 8.4.14 (fig.), 8.4.17–8.4.20
parameters affecting, 8.1.5–8.1.8, 8.1.9 (fig.)
selectivity, 8.1.7, 8.1.8, 8.1.9 (fig.)
in mass spectrometry
definitions of, compared, 16.1.20 (fig.)
effects on peaks, 16.1.19 (fig.)
in X-ray crystallography, 17.3.3–17.3.5
Resolving gels, *see* Separating and stacking gels
Restricted items, importing, *see* Importing-biological materials

BOSTON UNIVERSITY CENTRAL LIBRARY

Restriction endonuclease digestion
buffers, A.4I.3
cross index of recognition sequences and, A.4I.2 (table)
for library cDNA definition, 19.2.21–19.2.23
single DNA sample with single restriction endonuclease, A.4I.1, A.4I.3
Retention factor, *see* Capacity, chromatography
Retroviral CCHC zinc fingers, 17.1.22
Reversed-phase high-performance liquid chromatography (RP-HPLC)
in amino acid analysis, 11.9.1, 11.9.3, 11.9.17–11.9.18, 11.9.29
buffer profiles, 11.2.7 (fig.)
capillary assembly for, 11.6.4–11.6.7
cleavage and, in gels, 11.3.1, 11.3.8, 11.3.10–11.3.11, 11.3.10–11.3.12
columns for, 11.6.11–11.6.12
to desalt samples after protein modification, 15.1.14–15.1.15
digestion and, enzymatic, 11.1.1, 11.1.4, 11.1.5, 11.1.10, 11.2.1, 11.2.4, 11.2.6–11.2.8
iodinated products separation by, 3.3.8–3.3.9, 3.3.17
laboratory equipment required, 1.1.5
peptide separation
at 5 to 500 pmol, 11.6.1–11.6.3
at 5 pmol, 11.6.13–11.6.4
in polishing stage of purification, 8.1.4
in polypeptide ligation, 18.3.5, 18.4.3
problems in, 11.6.13–11.6.14
properties of proteins as basis for, 1.1.4, 1.1.5
of recombinant proteins
insoluble, 6.1.14
interleukin 2, 6.5.8–6.5.9
SDS inhibition of, 11.3.1
stationary and mobile phase selection, 11.6.12–11.6.13
tubing for, 11.6.3
Riboflavin, as photopolymerization catalyst, 7.4.5, 7.4.8
Ribonucleoprotein particles, 4.2.47
Ribosome binding site, in *E. coli* expression systems, 5.1.2
Ribosome-inactivating protein fold, 17.1.41
Ribosomes, density shift using digitonin, 4.2.48
Ricin, 4.2.40, 4.2.48
Ricinus communis (RCA), in glycoprotein purification, 9.1.2 (table), 9.1.9
Rink amide resin for polypeptide synthesis, 18.4.2 (table)
RIPA buffer, *see* RadioImmunoPrecipitation Assay buffer
RLE (Run Length Encoding), 10.12.7–10.12.8
RNA
alkali treatment in hydrolysis of, 13.1.2
-binding motifs and domains, 17.1.20–17.1.24
in density shift using colloidal gold conjugates, 4.2.41
double-stranded RNA-binding domain, 17.1.22
enzymes in replication, 17.1.29–17.1.32
hydroxylapatite chromatography of, 8.6.2 (table), 8.6.7–8.6.9
mRNA sequences, analysis using BLAST, 2.5.21–2.5.23
UV absorption spectroscopy of, 7.2.13–7.2.14
RNA polymerase, T7 RNA polymerase promoter, 5.1.2, 5.2.5, 5.2.6, 5.2.15
RNA translation, in *E. coli* expression systems, 5.1.2–5.1.3
RNase
endoproteinase digestion of, 11.1.6 (table)
in recombinant expression systems, 6.1.7, 6.5.3
Rodent cell lines, for recombinant protein production, 5.9.3 (table)
Rop, 17.1.22
Rotors, *see* Centrifuges
RP-HPLC, *see* Reversed-phase high-performance liquid chromatography
*Rsr*II site, in thioredoxin gene fusion expression vectors, 6.7.1–6.7.2, 6.7.4
RTX-100 buffer, UNIT 11.2, 11.2.5

S

S phase, mammalian cell protein production and, 5.9.12
Saccharide modifications, defined, 12.1.8
Saccharomyces cerevisiae expression systems
advantages, 5.8.14
antithrombin III, 5.6.3–5.6.4
applications, 5.6.1
for heterologous proteins
feed rate, 5.8.7, 5.8.14
large-scale, 5.8.6–5.8.8
production yield, 5.8.14 (table)
small-scale, 5.8.1–5.8.4
vs. *P. pastoris*, 5.7.1, 5.8.14 (table)
post-translational modifications, conformation, and function, 5.6.5–5.6.6, 5.7.9–5.7.11
production yield, attaining, 5.6.4–5.6.5
secretion to extracellular medium, 5.6.6
time frame and future prospects, 5.6.6
transformation efficiency in, 19.2.38
vectors and host strains, 5.6.1 (table), 5.6.2–5.6.3
S-adenosylmethionine (SAM), in carboxylmethylation, 14.3.1, 14.3.4, 14.3.10
Safelight conditions of darkroom, 10.11.2
Safety considerations
biohazards, A.2A.1–A.2A.2
chemicals, A.2A.2–A.2A.24
for electrophoresis, 10.1.1–10.1.2
general lab rules, APPENDIX 2A
in ^{32}P labeling, 13.2.1
for working with radioactivity, APPENDIX 2B
Salivary gland, centrifugation, 4.2.8
Salmon sperm DNA
preparation of, A.4H.7
sheared, preparation of, 19.2.28–19.2.29
Salt
concentrations, in ion-exchange chromatography
for batch adsorption and step-gradient elution, 8.2.10–8.2.13
determination of, 8.2.18–8.2.19
optimization, 8.2.25–8.2.27
contamination in gel electrophoresis, 10.1.33
in hydrophobic-interaction chromatography, 8.4.4–8.4.6, 8.4.10–8.4.11, 8.4.17–8.4.20
in inclusion body extraction, 6.3.9
Salt fractionation, of recombinant interleukin 1β, 6.2.12
Salt precipitation
protein membrane fractionation, A.3F.2
of recombinant proteins, 6.2.8
Salting out
ammonium sulfate
advantages as agent for salting out, 4.5.29
concentration, for protein precipitation, 4.5.5, 4.5.7, 4.5.28
combination with organic cosolvents for protein precipitation, 4.5.14–4.5.15
protein-protecting properties of, 4.5.28
saturated solutions, preparation of, 4.5.28
pH and, 4.5.5, 4.5.7
pilot experiment for, 4.5.7 (fig.)
precipitates, collection of, 4.5.8
selective precipitation by, 4.5.5–4.5.8, 4.5.28–4.5.29
steps for, 4.5.6 (fig.)
Salvage pathway in mammalian cells, 5.9.9, 5.9.10
Sample resolution, loss of, during capillary electrophoresis, 10.13.15
Sample size, and matrix selection, GF chromatography, 8.3.2–8.3.3
Sample tailing, in capillary electrophoresis, 10.13.15
Sample volume, GF chromatography
maximizing, 8.3.25–8.3.26
for protein fractionation, 8.3.16
and resolution, 8.3.11
Saturation of acceptor, in ligand-binding theory, A.5A.8, A.5A.10
SavvySearch, 2.4.16–2.4.17
SBA, in glycoprotein purification, 9.1.3 (table)
Scanning transmission electron microscopy
generally, 17.2.3, 17.2.22 (fig.), 17.2.23
in recombinant protein characterization, 7.1.7 (table)
Scanning window averaging technique, 2.2.3–2.2.5, 2.2.10
Scatchard plots
for kinetic assays, 3.5.8
in ligand-binding analysis, A.5A.7 (fig.), A.5A.17–A.5A.26, A.5A.35
Scatchard transformation, in ligand-binding theory, A.5A.16, A.5A.25–A.5A.26
Scattering cells
choice of, 7.8.12
clarification of, 7.8.12
Scoring matrices in sequence analysis, 2.1.7–2.1.8
SDS, *see* Sodium dodecyl sulfate
SDS micelles, in buffers for capillary electrophoresis, 10.13.14
SDS-PAGE, *see* Sodium dodecyl sulfate-polyacrylamide gel electrophoresis
SDS precipitation, *see* Sodium dodecyl sulfate (SDS) precipitation
Search engines, World Wide Web, 2.4.16
sec6 mutant, 4.2.22
Secondary processing, in protein purification, 1.3.1
Secondary structure
prediction from sequence
Chou and Fasman method, 2.3.3–2.3.5, 2.3.6 (fig.), 2.3.8–2.3.9 (fig.), 2.3.10 (fig.)
compact domains, 2.3.1
comparison of methods, 2.3.11–2.3.18
EMBL Profile Neural Network method, 2.3.2–2.3.2, 2.3.7
Garnier, Osguthorpe, and Robson method, 2.3.5–2.3.7
groups of proteins involved, 2.3.1
Guzzo and Prothero method, 2.3.1
helical net, 2.3.2
helical wheel method, 2.3.1–2.3.2, 2.3.7–2.3.8
hydrophobic residues, 2.3.1
Lim's method, 2.3.2
polar residues, 2.3.1

SNA, in glycoprotein purification, 9.1.3 (table)
SNAP, *see* Soluble NEM-sensitive attachment protein (SNAP)
SNARE receptor, in transport, 5.9.10
Sodium azide, 8.6.8
Sodium bromide (NaBr), 4.2.34
Sodium butyrate, in mammalian cell culture for protein expression, 5.9.13
Sodium carbonate, in extrinsic protein extraction from membranes
  applications, 4.2.48–4.2.49
  merits and limitations, 4.2.7
  method, 4.2.42–4.2.43
  requirements, 4.2.51
Sodium cholate, A.1B.2
Sodium cyanoborohydride
  in modification of amino groups, 15.2.11–15.2.13
  in radiolabeling, 3.3.12
Sodium deoxycholate, A.1B.2
Sodium dodecyl sulfate (SDS)
  for adsorbed proteins, 11.10.8–11.10.9
  capillary electrophoresis, 10.9.6–10.9.7
  denaturation of glycoproteins, 12.4.2–12.4.3, 12.4.5–12.4.6, 12.4.14
  in digestion
    enzymatic in solution, 11.1.2 (table), 11.1.5–11.1.7, 11.1.13–11.1.16
    in gels, 11.3.4–11.3.5, 11.3.8
  in electroblotting proteins from gels, 10.7.12, 10.7.13
  in inclusion body extraction, 6.3.8
  for lysis of radiolabeled cells, 13.2.4
  precipition, protein detection in polyacrylamide gels, 10.6.1, 10.6.6, 10.6.8
  in recombinant protein stability, 6.1.16
Sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE)
  ammonium persulfate in, 10.1.31–10.1.32
  for analysis of disulfide bond formation, 14.1.8–14.1.9, 14.1.13, 14.1.14
  continuous, 10.1.13–10.1.14
  digestion
    and amino acid analysis, 11.3.6–11.3.8, 11.4.6
    chemical, 11.5.7
    enzymatic, in presence of SDS, 11.1.5
    in gels, 11.3.8
  for N-terminal sequencing, 11.10.9–11.10.10, 11.10.36
  electricity and, 10.1.1–10.1.3
  electroblotting from gels, UNIT 10.7
  of glycosylation inhibitors, 12.3.6
  in gradient gels, 10.1.17–10.1.20
  high-resolution, for peptide mapping, 7.3.5–7.3.6, 7.3.17–7.3.22
  vs. IEF, 10.2.6–10.2.7
  Laemmli gel method (discontinuous), 10.1.3–10.1.9, 10.1.29
  in macromolecular crystallization, 17.4.10
  molecular weights
    calculating, 10.1.29–10.1.31, 10.1.33
    as factor in, 10.1.30–10.1.31
    of peptide standards, 10.1.11 (table)
    of protein standards, 10.1.7 (table)
  in multiple gels
    gradient, 10.1.21–10.1.23, 10.1.32
    gradient minigels, 10.1.26–10.1.27, 10.1.34
    single-concentration, 10.1.15–10.1.17
  in N-linked oligosaccharide chain estimates, 12.4.7
  one-dimensional, of recombinant proteins, 5.2.9, 5.2.16
  phosphorylation and, 13.1.2
  for phosphorylation studies
    direct analysis of kinases, 13.8.10
    permeabilization for, 13.8.6, 13.8.9
  of protein in gel slices from, 7.3.6–7.3.8
    reduction and alkylation, 11.3.6–11.3.7
    of separated proteins, 11.3.1
  precast gels, 10.1.30
  protein band quality, factors in, 10.1.32–10.1.33
  protein detection in gels
    with fixation, UNIT 10.5
    without fixation, UNIT 10.6
  purification methods, mobility-shift assay, 9.7.6–9.7.9
  of recombinant proteins
    bovine growth hormone, 6.5.4
    in characterization, 7.1.2
    guanidine hydrochloride removal, 6.3.6–6.3.7
    HIV-1 integrase, 6.5.24 (fig.)
    insoluble, 6.1.12–6.1.13
    interleukin 1β, 6.2.5, 6.2.6 (fig.), 6.2.11, 6.2.13
  reducing and nonreducing, 10.1.33, 14.1.1, 14.1.8–14.1.9, 14.1.13, 14.1.14
  in single-concentration minigels, 10.1.23–10.1.26
  temperature in, 10.1.32, 10.1.33, 10.1.34
  Tris-tricine system
    of nonurea peptides, 10.1.11–10.1.13, 10.1.31
    of peptides, 10.1.9–10.1.11, 10.1.31
  two-dimensional gel electrophoresis, 4.30
  in ultrathin gels, 10.1.14–10.1.15
  vs. UV absorption spectroscopy, 7.2.14
  vertical format precast gel compatibility, 10.1.9 (table)
  for X-ray crystallography sample preparation, 17.3.6–17.3.7
  See also Sodium dodecyl sulfate (SDS)

labeling strategies, 3.3.1 (table)
in model protein construction, 7.1.7–7.1.8
in spectrophotometric determination of protein concentration
absorbance, 3.1.1–3.1.2, 3.1.4–3.1.6
fluorescence emission, 3.1.3, 3.1.4–3.1.5
transitions of, electronic, 7.6.1, 7.6.3 (fig.), 7.6.16, 7.6.17 (fig.)
UV absorption spectroscopy of, UNIT 7.2, 3.4.7 (fig.), 3.4.9–3.4.10, 3.4.20
Tyrosine kinases
assay for, 13.7.11–13.7.8
protein kinase, post-translational modifications in insect cells, 5.4.3
in recombinant expression systems, infolding, 6.1.15
in tribrid proteins, 19.2.37
Tyrosine phosphatases, in phosphoprotein digestion, 13.5.4, 13.5.6
Tyrosine-phosphorylated peptides, *see* Peptides, tyrosine-phosphorylated

U

Ubiquitin
as molecular weight standard for MALDI-MS, 7.10.11 (table)
for protein characterization, 6.1.3
Udy dye–binding assay, 3.4.21
UEA-I, in glycoprotein purification, 9.1.3 (table)
Ultracentrifugation
analytical, UNIT 7.5
for X-ray crystallography samples, 17.3.9–17.3.11
Ultrafiltration
applications, 4.4.1
centrifugal, for concentration or desalting, 4.4.8–4.4.9
concentration polarization, 4.4.11
membrane selection and characteristics, 4.4.4–4.4.5, 4.4.6, 4.4.9–4.4.13
precipitation of protein, 4.4.12
of recombinant protein expression systems, interleukin1β, 6.2.8
in recombinant soluble protein purification, 1.3.1
rejection of solute, 4.4.11
tangential-flow, for diafiltration or concentration, 4.4.6–4.4.8
through asymmetric membrane disks, for concentration or dialysis, 4.4.4–4.4.6, 4.4.12 (table)
volume of filtrate for, 4.4.11
Ultrathin gels, casting and running, 10.1.14–10.1.15
Ultraviolet absorption spectroscopy
in capillary electrophoresis, 10.9.2–10.9.3, 10.9.11
in protein concentration determination 3.1.1–3.1.2, 3.1.4–3.1.6
of recombinant proteins
absorption flattening, 7.2.16
applications, 7.2.1–7.2.2
conventional scanning instruments, 7.2.14–7.2.15
using far-UV absorption spectra, 7.2.14
HPLC with diode-array detector, 7.2.10–7.2.12, 7.2.14–7.2.17, 7.2.18 (fig.), 7.2.19 (fig.)
intepreting near-UV spectra, 7.2.5–7.2.10
using near-UV absorption spectra, 7.2.2–7.2.5, 7.2.13–7.2.14, 7.2.16
pH in, 7.2.15
photooxidation of tryptophan, 7.2.15
temperature in, 7.2.14–7.2.15

BOSTON UNIVERSITY MEDICAL CENTER LIBRARY

in recombinant protein characterization, 7.1.6 (table)
in total protein quantitation
absorption spectra, 3.4.19 (fig.), 3.4.20
interfering compounds, 3.4.18 (table)
method, 3.4.10
molar absorption coefficients, 3.4.9–3.4.10
Ultraviolet light
lamps, 7.2.2, 7.2.15 (fig.), 7.2.16
wavelengths, 10.12.5
Ultrogel AcA54, 6.2.6, 6.2.6 (fig.), 6.2.8
Undecagold, for labeling in electron microscopy, 17.2.21
Unfolding of proteins
curve, 7.4.9 (fig.)
free energy change for, 7.4.6, 7.4.10
kinetics of, 7.4.6, 7.4.9–7.4.12
study via titration curve analysis, 7.3.13–7.3.15
See also Folding of proteins
Uniform resource locator (URL), 2.4.13–2.4.14
Unweighted Pair-Group Method using Arithmetic Averages (UPGMA), 10.12.12 (fig.)
URA3 gene, 5.6.3
Urea
in aggregation, 6.4.6
avoiding protein modification by, 11.10.8
concentration and reversible unfolding transition, 6.4.4
in cysteine modification, 15.1.2–15.1.3
in CZE, effect on isoelectric buffers, 10.13.1, 10.13.4–10.13.5
in enzymatic digestion of proteins in gels, 11.3.5
in glycoprotein denaturation, 12.4.14
in solution, 11.1.2 (table), 11.1.4–11.1.5, 11.1.13–11.1.16
in folding, 6.5.3
in IEF, 10.4.4, 10.4.17, 10.4.33
recombinant proteins and
bovine growth hormone extraction and purification, 6.5.19, 6.5.20
inclusion body extraction, 6.1.12 (fig.), 6.1.13–6.1.14, 6.3.2
soluble proteins, 6.1.5–6.1.6
Urea-gradient gel electrophoresis
advantages of, 7.4.7
calculations from, 7.4.9–7.4.11, 7.4.10 (fig.)
method, 7.4.1–7.4.5
patterns produced by proteins, 7.4.11 (fig.), 7.4.12 (fig.)
preparation of gel for, 7.4.1 (fig.), 7.4.3 (fig.)
of recombinant proteins, 7.1.4 (table), 7.1.7
unfolding curve produced by, 7.4.9 (fig.)
Uridine monophosphate, two-dimensional electrophoresis, 13.3.7

V

Vaccinia infection, effects of, 5.11.2–5.11.3
Vaccinia virus
safety precautions, 5.11.5
expression system
replication cycle, 5.11.1–5.11.2
vector, 5.11.3–5.11.5
MVA stock
preparation of, 5.12.8–5.12.9
titration by immunostaining, 5.12.9–5.12.10
stocks, cell culture preparation
general, 5.12.4–5.12.5
monolayer cells, 5.12.2–5.12.3
suspended cells, 5.12.3–5.12.4
chicken embryo fibroblasts preparation, 5.12.6–5.12.8
titration by plaque assay, 5.12.5–5.12.6
Van't Hoff enthalpy, 7.9.11–7.9.12
Variant surface glycoprotein (VSG), 12.5.10
Vectastain ABC kit (Vector), use in immunoprobing, 10.10.3–10.10.4
Vectors
for biosynthesis of polypeptides, 18.4.8
database for BLASTN, TBLASTN, and TBLASTX, 2.5.5
for heterologous expression in yeast
galactose-regulated, 5.8.1–5.8.3, 5.8.6–5.8.8
glucose-repressible *ADH2*, 5.8.3
glycolytic gene promotors, 5.8.4
λ vectors, for bacteriophage cDNA library, 19.3.1–19.3.2
pET, 9.4.2, 9.4.3 (fig.)
pGEX, 6.6.1–6.6.5, 6.6.19
pTE432 vector, 5.6.1 (table)
pTK46 vector, 5.6.1 (table)
pTYB1 and sequence of cloning/expression region, 18.4.13 (fig.)
pYBDT-10 vector, 5.6.1 (table)
pYEULS1 vector, 5.6.1 (table)
requirements for, 6.1.2
secretion
in inclusion body formation, 6.1.3
localizing proteins, 6.1.5–6.1.7, 6.1.8 (fig.)
YpGX235 vector, 5.6.3–5.6.4
YpGX262 vector, 5.6.5
See also Expression vectors
Vector systems, in recombinant protein purification, 1.2.3
Velocity
in differential centrifugation
applications, 4.2.45–4.4.46
merits and limitations, 4.2.1
method, 4.2.7–4.2.9
requirements, 4.2.49
sedimentation, 4.1.2
in ligand-binding theory
initial and maximal, A.5A.3
sedimentation, A.5A.9
Vertical gels
precast in SDS-PAGE, 10.1.9 (table)
slab in Laemmli method, 10.1.4–10.1.9
Vesicles
density gradient centrifugation in nonionic solutes, 4.2.47
density shift using gold conjugates, 4.2.48
electrophoresis, 4.2.24–4.2.29, 4.2.30 (fig.), 4.2.47
endosomal carrier vesicles, 4.3.2 (table), 4.3.4, 4.3.14, 4.3.15–4.3.16, 4.3.18
gel filtration, 4.2.22–4.2.24, 4.2.47
lectin adsorption, 4.2.5–4.2.6, 4.2.51
solid-phase immunoadsorption, 4.2.5
See also Endosomes
Vesicles, in transport, 5.9.8 (fig.), 5.9.10
Vesicular stomatitis virus
G protein, implantation and internalization, 4.3.3–4.3.5, 4.3.14
stock preparation, 4.3.5
Viability
in baculovirus expression system, determining, 5.5.13
of cells, determining, A.3C.8–A.3C.10
4-Vinylpyridine
alkylation of cysteine residues using, 15.1.2 (table), 15.1.8
for alkylation of peptides in digest mixtures, 11.1.10
Viral-coat proteins, 17.1.43–17.1.44
Virtual libraries, defined, 2.4.16
Viruses, vectors, for mammalian expression systems, 5.9.5–5.9.6
Viscosity
of centrifugation media, 4.1.5–4.1.7, 4.2.14
of recombinant expression systems, 6.1.7, 6.2.4
in sedimentation, 4.1.2
Viscosity radius, of dextran, molecular size calibration, 8.3.21
Viscous fingering, in GF chromatography, 8.3.11–8.3.12
Void fraction, and bed compression, GF chromatography, 8.3.28
Void marker, GF chromatography (recipe), 8.3.23
Void volume V_0
column for GF chromatography, 8.3.10
measuring, 8.3.12
for protein fractionation, 8.3.27
von Heijne hydropathy scale, 2.2.3
VVA or VVL in glycoprotein purification, 9.1.3 (table)

W

Wang resin for polypeptide synthesis, 18.4.2 (table)
WI-38 cell line, for recombinant protein expression, 5.9.3 (table), 5.9.4
Waste, disposal of,
biohazardous, A.2A.2
chemical, A.2A.7–A.2A.24
Weight absorption coefficients, 3.4.9–3.4.10, 3.4.16
Western blotting, *see* Immunoblotting
WGA, *see* Wheat germ agglutinin
Whatman 3MM paper, 13.3.3–13.3.4, 13.3.7
Wheat germ acid phosphatase, 13.5.6
Wheat germ agglutinin (WGA)
affinity chromatography in organelle purification
applications, 4.2.48
merits and limitations, 4.2.5–4.2.6
method, 4.2.33–4.2.35
requirements, 4.2.51
-agarose affinity chromatography, 9.1.7–9.1.8
in glycoprotein purification, 9.1.2 (table)
structure, 17.1.25
in VSV G protein implantation and internalization, 4.3.3–4.3.5
Window scanning averaging technique, 2.2.3–2.2.5, 2.2.10
World Wide Web (WWW)
background of, 2.4.13
browsers, 2.4.14–2.4.15
ExPASy site for amino acid analysis, 11.9.28, 11.9.35–11.9.36
finding information on, 2.4.16–2.4.18
internet *vs.* intranet, 2.4.15
mass spectrometry sites, 16.2.8 (table)
navigation on, 2.4.13–2.4.14
PROPSEARCH site for amino acid analysis, 11.9.28, 11.9.35–11.9.36
resources, 2.1.14
sequence similarity via, UNIT 2.5
sites of interest (table), 2.4.15

X

X-Cys motifs, for protein synthesis, 18.4.1
Xgal assay
for *lacZ* gene activation, 19.2.9–19.2.10
plate preparation (recipe), A.4L.3
XK columns, 6.3.4–6.3.6
X-Omat AR film, 10.11.1–10.11.4
X-ray crystallography
crystallization protocol, UNIT 17.4

PRIVATE COPY UNIVERSITY LIBRARY

engineering of proteins for, 17.3.11–17.3.13
physical characterization of sample, 17.3.9–17.3.11
principles of
data collection, 17.3.2
light beams, 17.3.1
phase determination, 17.3.2–17.3.3
Ramachandran plot, 17.3.6
refinement, 17.3.5–17.3.6
resolution, 17.3.3–17.3.5
vector components and calculations, 17.3.1–17.3.2
of recombinant proteins, 6.1.16, 6.1.18
relationship to electron microscopy, 17.2.1, 17.2.23
sample preparation, 17.3.6–17.3.8
X-ray diffraction, of recombinant proteins, 7.1.7 (table), 7.1.8
X-ray film, 10.5.9

Current Protocols in Protein Science

Supplement 17 **New Topics** **September 1999**

In this Supplement ...

☑ Metabolic Labeling with Amino Acids UNIT 3.7

☑ Synthesis and Application of Peptide Dendrimers As Protein Mimetics UNIT 18.5

☑ Detection of Protein-Protein Interactions by Coprecipitation UNIT 19.4

☑ Overview of the Quantitation of Protein Interactions UNIT 20.1

☑ Measuring Protein Interactions by Optical Biosensors UNIT 20.2

Coming soon ...

☑ Immunoprecipitation

☑ Phosphopeptide Mapping

☑ Large-Zone Analytical Gel Filtration

This supplement includes important new topics to bring your CPPS subscription up to date with the latest methodology. Also included is a reader response card for forwarding us your comments and suggestions. Please see next page for a full listing of contents and instructions for inserting pages.

For more detailed information about new and upcoming topics, visit the Current Protocols Home Page at *www.wiley.com/cp*.

If you have questions about your subscription, call Customer Service at 800-825-7550.

Routing List

After filing, you may wish to route this cover sheet to other Current Protocols users to keep them informed of the new topics.

FULL CONTENTS OF SUPPLEMENT 17

Instructions for Adding Pages to Core Manual

Full contents for Supplement 17 are listed below, with instructions for removing old pages and inserting new pages. Every page included with Supplement 17 is labeled as such beneath the page number.

Remove pages	Insert pages	Subject	Primary change/notes
VOLUME 1			
Main TOC: 1-6	Main TOC: 1-6	Main table of contents	Reflects new material in Chaps. 3, 18, 19, and Appendices, and new Chapter 20
Ch 3:1-2	Ch 3:1-2	Chapter 3 contents	Reflects new *UNIT 3.7*
3.0.1-3.0.2	3.0.1-3.0.2	Chapter 3 introduction	Revision
—	3.7.1-3.7.10	Metabolic labeling with amino acids	New *UNIT 3.7*
6.7.9-6.7.10	6.7.9-6.7.10	Expression and purification of thioredoxin fusion proteins	Revision
Ch 7:1-2	Ch 7:1-2	Chapter 7 contents	Reflects new *UNIT 7.10*
Ch 10:3	Ch 10:3	Chapter 10 contents	Reflects new *UNIT 10.13*
10.0.1-10.0.3	10.0.1-10.0.3	Chapter 10 introduction	Revision
VOLUME 2			
—	16.0.1-16.0.2	Chapter 16 introduction	New introduction
Ch 18:1-2	Ch 18:1-2	Chapter 18 contents	Reflects new *UNIT 18.5*
18.0.1-18.0.2	18.0.1-18.0.2	Chapter 18 introduction	Revision
18.3.13-18.3.14	18.3.13-18.3.14	Selecting synthetic peptides for production of antibodies	Revision
—	18.5.1-18.5.35	Synthesis and application of peptide dendrimers as protein mimetics	New *UNIT 18.5*
Ch 19:1	Ch 19:1	Chapter 19 contents	Reflects new *UNIT 19.4*
19.0.1	19.0.1	Chapter 19 introduction	Revision
19.2.7-19.2.8	19.2.7-19.2.8	Interaction trap/two-hybrid system to identify interacting proteins	Revision
—	19.4.1-19.4.9	Detection of protein-protein interactions by coprecipitation	New *UNIT 19.4*
—	New Chapter 20 & tab (40 pages)	Quantitation of protein interactions	New Chapter 20
NOTE: Insert Chapter 20 tab with the reinforcement strip facing back.			
Appendices: 1-2	Appendices: 1-2	Appendices	Reflects new *APPENDIX 1D*
—	A.1D.1-A.1D.8	Common conversion factors	New *APPENDIX 1D*
—	Suppl. 17 index (2 pages)	New supplement index	New entries covering Supplement 17

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Table of Contents, Volumes 1 and 2

i Foreword

iii Preface

vii Contributors

1 Strategies of Protein Purification and Characterization

1.1 Overview of Protein Purification and Characterization

1.2 Strategies for Protein Purification

1.3 Protein Purification Flow Charts

2 Computational Analysis

2.1 Computational Methods for Protein Sequence Analysis

2.2 Hydrophobicity Profiles for Protein Sequence Analysis

2.3 Protein Secondary Structure Prediction

2.4 Internet Basics

2.5 Sequence Similarity Searching Using the BLAST Family of Programs

3 Detection and Assay Methods

3.1 Spectrophotometric Determination of Protein Concentration

3.2 Quantitative Amino Acid Analysis

3.3 In Vitro Radiolabeling of Peptides and Proteins

3.4 Assays for Total Protein

3.5 Kinetic Assay Methods

3.6 Biotinylation of Proteins in Solution and on Cell Surfaces

3.7 Metabolic Labeling with Amino Acids

4 Extraction, Stabilization, and Concentration

4.1 Overview of Cell Fractionation

4.2 Purification of Organelles from Mammalian Cells

4.3 Subcellular Fractionation of Tissue Culture Cells

4.4 Desalting, Concentration, and Buffer Exchange by Dialysis and Ultrafiltration

4.5 Selective Precipitation of Proteins

BCU IAST/CENTRAL UNIVERSITY LIBRARY

Copyright © 1999 by John Wiley & Sons, Inc.

5 Production of Recombinant Proteins

5.1 Production of Recombinant Proteins in *Escherichia coli*

5.2 Selection of *Escherichia coli* Expression Systems

5.3 Fermentation and Growth of *Escherichia coli* for Optimal Protein Production

5.4 Overview of the Baculovirus Expression System

5.5 Protein Expression in the Baculovirus System

5.6 Overview of Protein Expression in *Saccharomyces cerevisiae*

5.7 Overview of Protein Expression in *Pichia pastoris*

5.8 Culture of Yeast for the Production of Heterologous Proteins

5.9 Overview of Protein Expression by Mammalian Cells

5.10 Production of Recombinant Proteins in Mammalian Cells

5.11 Overview of the Vaccinia Virus Expression System

5.12 Preparation of Cell Cultures and Vaccinia Virus Stocks

5.13 Generation of Recombinant Vaccinia Viruses

5.14 Characterization of Recombinant Vaccinia Viruses and Their Products

5.15 Gene Expression Using the Vaccinia Virus/T7 RNA Polymerase Hybrid System

6 Purification of Recombinant Proteins

6.1 Overview of the Purification of Recombinant Proteins Produced in *Escherichia coli*

6.2 Preparation of Soluble Proteins from *Escherichia coli*

6.3 Preparation and Extraction of Insoluble (Inclusion-Body) Proteins from *Escherichia coli*

6.4 Overview of Protein Folding

6.5 Folding and Purification of Insoluble (Inclusion-Body) Proteins from *Escherichia coli*

6.6 Expression and Purification of GST Fusion Proteins

6.7 Expression and Purification of Thioredoxin Fusion Proteins

7 Characterization of Recombinant Proteins

7.1 Overview of the Characterization of Recombinant Proteins

7.2 Determining the Identity and Purity of Recombinant Proteins by UV Absorption Spectroscopy

7.3 Determining the Identity and Structure of Recombinant Proteins

7.4 Transverse Urea-Gradient Gel Electrophoresis

7.5 Analytical Ultracentrifugation

7.6 Determining the CD Spectrum of a Protein

7.7 Determining the Fluorescence Spectrum of a Protein

7.8 Light Scattering

7.9 Measuring Protein Thermostability by Differential Scanning Calorimetry

7.10 Characterizing Recombinant Proteins Using HPLC Gel Filtration and Mass Spectrometry

BCU IAS / CENTRAL UNIVERSITY LIBRARY

8 Conventional Chromatographic Separations

8.1 Overview of Conventional Chromatography
8.2 Ion-Exchange Chromatography
8.3 Gel-Filtration Chromatography
8.4 Hydrophobic-Interaction Chromatography
8.5 Chromatofocusing
8.6 Hydroxylapatite Chromatography

9 Affinity Purification

9.1 Lectin Affinity Chromatography
9.2 Dye Affinity Chromatography
9.3 Affinity Purification of Natural Ligands
9.4 Metal-Chelate Affinity Chromatography
9.5 Immunoaffinity Chromatography
9.6 Purification of Sequence-Specific DNA-Binding Proteins by Affinity Chromatography
9.7 Purification of DNA-Binding Proteins Using Biotin/Streptavidin Affinity Systems

10 Electrophoresis

10.1 One-Dimensional SDS Gel Electrophoresis of Proteins
10.2 One-Dimensional Isoelectric Focusing of Proteins in Slab Gels
10.3 One-Dimensional Electrophoresis Using Nondenaturing Conditions
10.4 Two-Dimensional Gel Electrophoresis
10.5 Protein Detection in Gels Using Fixation
10.6 Protein Detection in Gels Without Fixation
10.7 Electroblotting from Polyacrylamide Gels
10.8 Detection of Proteins on Blot Membranes
10.9 Capillary Electrophoresis of Proteins and Peptides
10.10 Immunoblot Detection
10.11 Autoradiography
10.12 Overview of Digital Electrophoresis Analysis
10.13 Capillary Electrophoresis of Peptides and Proteins Using Isoelectric Buffers

11 Chemical Analysis

11.1 Enzymatic Digestion of Proteins in Solution
11.2 Enzymatic Digestion of Proteins on PVDF Membranes
11.3 Digestion of Proteins in Gels for Sequence Analysis
11.4 Chemical Cleavage of Proteins in Solution
11.5 Chemical Cleavage of Proteins on Membranes

continued

BCU/ASH / CENTRAL UNIVERSITY LIBRARY

11.6 Reversed-Phase Isolation of Peptides
11.7 Removal of N-Terminal Blocking Groups from Proteins
11.8 C-Terminal Sequence Analysis
11.9 Amino Acid Analysis
11.10 N-Terminal Sequence Analysis of Proteins and Peptides

12 Post-Translational Modification: Glycosylation

12.1 Overview of Glycoconjugate Analysis
12.2 Metabolic Radiolabeling of Animal Cell Glycoconjugates
12.3 Inhibition of N-Linked Glycosylation
12.4 Endoglycosidase and Glycoamidase Release of N-Linked Oligosaccharides
12.5 Detection of Glycophospholipid Anchors on Proteins

13 Post-Translational Modification: Phosphorylation and Phosphatases

13.1 Overview of Protein Phosphorylation
13.2 Labeling Cultured Cells with $^{32}P_i$ and Preparing Cell Lysates for Immunoprecipitation
13.3 Phosphoamino Acid Analysis
13.4 Detection of Phosphorylation by Immunological Techniques
13.5 Detection of Phosphorylation by Enzymatic Techniques
13.6 Production of Antibodies That Recognize Specific Tyrosine-Phosphorylated Peptides
13.7 Assays of Protein Kinases Using Exogenous Substrates
13.8 Permeabilization Strategies to Study Protein Phosphorylation

14 Post-Translational Modification: Specialized Applications

14.1 Analysis of Disulfide Bond Formation
14.2 Analysis of Protein Acylation
14.3 Analysis of Protein Prenylation and Carboxyl-Methylation

15 Chemical Modification of Proteins

15.1 Modification of Cysteine
15.2 Modification of Amino Acids

BCU IASI / CENTRAL UNIVERSITY LIBRARY

16 Mass Spectrometry

16.1 Overview of Peptide and Protein Analysis by Mass Spectrometry
16.2 Matrix-Assisted Laser Desorption/Ionization Time-of-Flight Mass Analysis of Peptides
16.3 Sample Preparation for MALDI Mass Analysis of Peptides and Proteins
16.4 In-Gel Digestion of Proteins for MALDI-MS Fingerprint Mapping
16.5 Searching Sequence Databases Over the Internet: Protein Identification Using MS-Fit
16.6 Searching Sequence Databases Over the Internet: Protein Identification Using MS-Tag
16.7 Enzymatic Approaches for Obtaining Amino Acid Sequence: On-Target Ladder Sequencing

17 Structural Biology

17.1 Overview of Protein Structural and Functional Folds
17.2 Overview of Macromolecular Electron Microscopy
17.3 Principles of Macromolecular X-Ray Crystallography
17.4 Crystallization of Soluble Macromolecules

18 Preparation and Handling of Peptides

CHAPTER 3
Detection and Assay Methods

INTRODUCTION

The success or failure of protein-centered projects can frequently be traced to the quality of the analytical procedures used to characterize the sample at different stages. Qualitative and quantitative analysis can aid in definition of the sample for the purpose of designing separations. A knowledge of the properties of the desired protein (e.g., whether it has a high aromatic amino acid content) can suggest methods of analysis that will help locate the desired protein in a complex mixture. Establishing the properties of an isolated protein creates benchmarks that future researchers can use to evaluate their protocols and final product. Accurate quantitation of the amount of protein at the beginning, middle, and end of a series of steps is the only valid way to evaluate the overall yield of a procedure. The observation of significant loss of protein following a particular purification procedure, without a substantial increase in the purity of the desired protein, would indicate that the procedure should be omitted or revised.

Several spectroscopic procedures for characterizing protein samples are described in *UNIT 3.1*. Measuring the absorbance of the aromatic amino acids in a protein at different wavelengths yields a very useful measure of protein concentration. This is nondestructive and requires very little sample or time. A more qualitative, but much more sensitive, evaluation is provided by fluorescence spectroscopy.

Another approach is amino acid analysis—qualitative analysis, to determine purity, and quantitative analysis, to provide concentrations—both of which are presented in *UNIT 3.2*. Procedures are also given for calculating amino acid ratios from primary analytical data. Significant advances that have improved the precision and sensitivity of amino acid analysis have reinvigorated this method, which had for some years been neglected.

A common method for enhancing the sensitivity of protein detection is to radiolabel the proteins, as detailed in *UNIT 3.3*. This approach may also be employed to help quantitate the binding of peptide to other molecules or for radioimmunoassays. Several procedures for iodination (introduction of ^{125}I or ^{131}I) are presented; the choice between them will depend on the sample type, the content of residues sensitive to oxidation, and the amino acids that are critical to function. Procedures for handling radioactive samples, for separating labeled from unlabeled peptides, and for iodination to equimolar or higher levels (using a mixture of radioactive and nonradioactive iodine isotopes) are also provided. When Tyr or His residues are absent, or cannot be iodinated because they are critical for function, alternative methods involving the incorporation of ^{14}C or ^{3}H may be employed instead. The methods described include labeling by acetylation at amino groups on lysine or at the amino terminus using the Bolton-Hunter reagent or acetic anhydride, by reductive alkylation, and by labeling at Lys residues with iodoacetic acid or iodoacetamide. Two synthetic methods, reduction of a peptide containing iodo-Tyr residues and incorporation of labeled amino acids, are also presented.

Measurement of the total protein content of a sample is discussed in *UNIT 3.4*. Three methods based on reduction of Cu^{2+} to Cu^{+} followed by chelation of the cuprous ion by various reagents (biuret, Hartree-Lowry, and bicinchinonic acid) are presented. In addition, a quantitative measure of total protein based on protein hydrolysis and the ninhydrin

BOSTON UNIVERSITY LIBRARY

reaction is described. The use of UV absorption, Coomassie dye binding, and weight analysis to determine protein content complete the presentation. Important considerations for performing these assays, such as dealing with interfering substances, are detailed throughout the unit.

Some aspects involved in the design of enzyme assays are discussed in *UNIT 3.5*. Parameters that affect both enzyme and substrate are evaluated and suggestions to optimize the quantitation of enzymatic activity are enumerated. The proper concentration range for conducting initial velocity measurements is presented, and different methods of data presentation and analysis are discussed.

Tagging a protein with a group that permits facile detection is an excellent way, for example, to study the movement of a protein through internalization or compartmentalization. A variety of reagents are available for attaching biotin to functional groups or the surface of a protein (*UNIT 3.6*). Detection and localization can be achieved by the strong and specific binding of avidin or streptavidin. These reactions can also be used to label proteins at cell surfaces.

Another highly sensitive approach to the detection of proteins is the incorporation of radiolabeled amino acids into proteins. Integration of a particular radiolabeled amino acid (i.e., [^{35}S]D-methionine or [^{3}H]leucine) can be achieved using the normal cellular machinery (*UNIT 3.7*). Both pulse-labeling methods that permit study of cellular trafficking and long-term labeling to increase the detection of relatively rare proteins are described.

Analytical assay methods to quantitate total protein content by biological activity will be presented in future updates to this chapter.

Metabolic Labeling with Amino Acids

Metabolic labeling techniques are used to study the biosynthesis, processing, intracellular transport, secretion, degradation and physical-chemical properties of proteins. In this unit, protocols are described for metabolically labeling mammalian cells with radiolabeled amino acids (Table 3.7.1). Cells labeled using these procedures are suitable for analysis by immunoprecipitation, characterization of cellular proteins, analysis of protein trafficking, and one- and two-dimensional gel electrophoresis (*UNITS 10.1-10.4*). The first protocols describe pulse-labeling (10 to 30 min) of mammalian cells in suspension with [^{35}S]methionine (see Basic Protocol), and necessary modifications for adherent mammalian cells (see Alternate Protocol 1). Alternate protocols are also presented for pulse-chase analysis (see Alternate Protocol 2) and long-term ("steady state") labeling (6 to 32 hr; see Alternate Protocol 3). This is followed by conditions for metabolic labeling of cells with radiolabeled amino acids other than [^{35}S]methionine (see Alternate Protocol 4). The degree of label incorporation can be determined by precipitation with trichloroacetic acid (TCA; see Support Protocol).

NOTE: All solutions and equipment coming into contact with living cells must be sterile, and aseptic technique should be used accordingly.

NOTE: All culture incubations should be performed in a humidified 37°C, 5% CO_2 incubator unless otherwise specified. Some media (e.g., DMEM) may require altered levels of CO_2 to maintain pH 7.4.

Table 3.7.1 Radiolabeled Amino Acids Used in Metabolic Labeling of Proteins

Amino acid[a]	Frequency (%)[b]	Radioisotope	Specific activity (Ci/mmol)	Comments[c]
Leucine	10.4	^{3}H	5-190	E
Serine	8.1	^{3}H	5-40	T, I

SAFETY PRECAUTIONS FOR WORKING WITH ^{35}S-LABELED COMPOUNDS

When working with radioactive materials, take appropriate precautions to avoid contamination of the experimenter and the surroundings. Carry out the experiment and dispose of wastes in an appropriately designated area, following guidelines provided by the local radiation safety officer (also see *APPENDIX 2B*).

Solutions containing ^{35}S-labeled compounds have been found to release volatile radioactive substances (Meisenhelder and Hunter, 1988). In addition to the usual safety practices followed when handling radioactive materials (see *APPENDIX 2B*), some extra precautions should be taken when using ^{35}S-labeled amino acids:

1. Vials containing ^{35}S-labeled compounds should always be handled in a designated fume hood equipped with an activated charcoal filter. This includes thawing the solution, opening the vial, and adding the radiolabeled amino acid to the labeling medium. Before opening, vials should be vented with a needle attached to a syringe packed with activated charcoal. Tissue culture hoods should not be used for this purpose, as they are likely to become contaminated.
2. Minimize exposure of ^{35}S-containing solutions to the air.
3. Use baths, incubators, and centrifuges designated for work with radioactive materials. Place a tray containing a layer of activated charcoal in the CO_2 incubator to reduce the amount of ^{35}S-labeled compounds released to the air during cell labeling. Alternatively, filters impregnated with activated carbon (β-Safe, Schleicher & Schuell) can be attached to the covers of tissue culture dishes.
4. Monitor areas used during labeling by conducting wipe tests.
5. Dispose of solid and liquid ^{35}S waste quickly and with appropriate precautions.

BASIC PROTOCOL

PULSE-LABELING OF CELLS IN SUSPENSION WITH [^{35}S]METHIONINE

Pulse-labeling of proteins is performed by incubating cells for short periods (≤30 min) in culture medium containing a radiolabeled amino acid. The conditions described below are optimized for labeling times of 10 to 30 min, but the same procedure can be used for periods up to 6 hr, although fewer cells and/or more labeling medium should be used for optimal results. Very short pulses (<10 min) may require special conditions (see Critical Parameters). For labeling times >6 hr, see Alternate Protocol 3. [^{35}S]methionine is the radiolabeled amino acid of choice for metabolic labeling of proteins because of its high specific activity (>800 Ci/mmol) and ease of detection. A potential disadvantage of [^{35}S]methionine is its low abundance (~1.8% of the average amino acid composition; see Table 3.7.1). For proteins that contain little (e.g., only one) or no methionine, other radiolabeled amino acids should be used (see Alternate Protocol 4).

Materials

[^{35}S]L-Methionine (>800 Ci/mmol) or ^{35}S-labeled protein hydrolyzate (>1000 Ci/mmol)
Pulse-labeling medium (see recipe), warmed to 37°C
Cell suspension (e.g., Jurkat, RBL, K562, BW5147, or T or B cell hybridomas), grown in a humidified 37°C, 5% CO_2 incubator or prepared from tissues (e.g., lymphocytes)
PBS (*APPENDIX 2E*), ice cold
Vacuum aspirator with trap for liquid radioactive waste

ECU IAST CENTRAL UNIVERSITY LIBRARY

Additional reagents and equipment for TCA precipitation (optional; see Support Protocol)

1. Thaw [^{35}S]methionine at room temperature and prepare a 0.1 to 0.2 mCi/ml working solution in prewarmed (37°C) pulse-labeling medium.

   CAUTION: *Volatile ^{35}S-containing compounds can be released during the labeling procedure (refer to Safety Precautions and APPENDIX 2B). Keep [^{35}S]methionine-containing medium in a tightly capped tube in a 37°C water bath until use. Do not let it sit >60 min at 37°C.*

2. Harvest 0.5–2 × 10^7 cells in suspension by centrifuging 5 min at 300 × *g*, room temperature.

3. Aspirate supernatant and resuspend cells by gently tapping the bottom of the tube. Add 10 ml prewarmed pulse-labeling medium. Mix by inversion of the tube and centrifuge 5 min at 300 × *g*, room temperature. Repeat this step once.

4. Resuspend cells at 5 × 10^6 cells/ml in prewarmed pulse-labeling medium and incubate 15 min in a 37°C water bath to deplete intracellular pools of methionine. Invert tube periodically to resuspend cells.

5. Centrifuge cells 5 min at 300 × *g*, room temperature, and aspirate supernatant.

6. Resuspend cells in 2 ml [^{35}S]methionine working solution (step 1). Cap tube tightly. Incubate cells 10 to 30 min (see Critical Parameters) in a 37°C water bath, resuspending frequently by gentle inversion of the tube.

   Alternatively, use a rotator placed in a 37°C incubator.

7. Centrifuge cells 5 min at 300 × *g*, 4°C, and aspirate supernatant. Resuspend with gentle swirling in 10 ml ice-cold PBS and repeat centrifugation.

   CAUTION: *The medium and wash are radioactive—follow applicable safety regulations for disposal.*

   Because of the short times and high concentrations of radiolabeled amino acids employed, pulse-labeling may not result in complete depletion of label from the medium. If this is the case, the labeling mixture can be reused. Collect the labeling medium containing [^{35}S]methionine or ^{35}S-labeled protein hydrolyzate and filter carefully through a 0.45-μm filter unit. Estimate the percentage of unincorporated radioactivity by scintillation counting aliquots of the labeling mixture before and after labeling the cells. Store the labeling mixture up to 2 months frozen at –20°C.

8. *Optional:* Determine amount of label incorporation by trichloroacetic acid (TCA) precipitation (see Support Protocol 1).

   Labeled cells are now ready for the desired processing and analysis. If cell pellets cannot be processed immediately, they can be kept on ice for a few hours or frozen at –80°C for several days. Thaw frozen cell pellets on ice before analysis. In most cases, freezing cells will not affect the biochemical properties of the proteins, but freezing and thawing cell extracts after solubilization with detergents (APPENDIX 1B) can cause dissociation of multisubunit complexes or proteolysis of labeled proteins.

BCU IAS CENTRAL UNIVERSITY LIBRARY

ALTERNATE PROTOCOL 1

PULSE-LABELING OF ADHERENT CELLS WITH [^{35}S]METHIONINE

Labeling of adherent cells is essentially the same as described for cells in suspension except that cells are labeled while attached to a dish. As with suspended cells, adherent cells are pulse-labeled 10 to 30 min (see Basic Protocol introduction). Alternatively, some adherent cells can be detached from plates by incubation for 10 min at 37°C with 10 mM EDTA in PBS (*APPENDIX 2E*) and labeled as a suspension (see Basic Protocol). This is particularly advantageous when labeling cells for pulse-chase experiments, because it simplifies handling of multiple samples and allows more uniform labeling of the cells.

Additional Materials (also see Basic Protocol)

Adherent cells (e.g., HeLa, NRK, M1, COS-1, CV-1, or fibroblasts or endothelial cells in primary culture)
100-mm tissue culture dishes

1. Grow adherent cells to 80% to 90% confluency in 100-mm tissue culture dishes.

   Depending on the cell type, a confluent 100-mm dish will contain 0.5–2 × 10^7 cells.

2. Prepare [^{35}S]methionine working solution (see Basic Protocol, step 1).

3. Aspirate culture medium from the dishes and wash twice by gently swirling with 10 ml prewarmed (37°C) pulse-labeling medium, aspirating medium after each wash.

4. Add 5 ml prewarmed pulse-labeling medium and incubate 15 min in a humidified 37°C, 5% CO_2 incubator to deplete intracellular pools of methionine.

5. Remove medium from cells, add 2 ml [^{35}S]methionine working solution (from step 2), and incubate 10 to 30 min in a CO_2 incubator.

   If necessary, as little as 1 ml of labeling medium per plate can be used. It is critical, however, that the plates sit on a perfectly horizontal surface during incubation to avoid drying of the cell monolayer.

6. Remove medium from cells. Wash once with 10 ml ice-cold PBS and remove PBS.

   CAUTION: *The medium and wash are radioactive—follow applicable safety regulations for disposal.*

   If significant detachment of cells occurs during labeling, it may be necessary to scrape the cells carefully in the [^{35}S]methionine-containing medium and transfer the suspension to a 15-ml centrifuge tube before centrifuging and washing with PBS.

7. Add 10 ml ice-cold PBS and scrape cells carefully with either a disposable plastic scraper or a rubber policeman.

8. Transfer the suspension to a 15-ml centrifuge tube, centrifuge 5 min at 300 × *g*, 4°C, and discard supernatant.

9. *Optional:* Determine amount of label incorporation by trichloroacetic acid (TCA) precipitation (see Support Protocol 1).

   Labeled cells are now ready for the desired processing and analysis (see Basic Protocol, step 8 annotation, if cells are not to be used immediately).

ECU IASI CENTRAL UNIVERSITY LIBRARY

PULSE-CHASE LABELING OF CELLS WITH [^{35}S]METHIONINE

ALTERNATE PROTOCOL 2

Pulse-chase protocols are used to analyze time-dependent processes, such as posttranslational modification, transport, secretion, or degradation of newly synthesized proteins. Cells in suspension or adherent cells are pulse-labeled with [^{35}S]methionine (see Basic Protocol and Alternate Protocol 1), after which they are incubated (chased) in complete medium containing excess unlabeled methionine, as described below.

Additional Materials (also see Basic Protocol and Alternate Protocol 1)

Chase medium (see recipe), 37°C

1. Prepare 0.5–2 × 10^7 cells per sample per time point, and pulse-label 10 to 30 min with 2 ml of 0.1 to 0.2 mCi/ml [^{35}S]methionine per 0.5–2 × 10^7 cells (see Basic Protocol, steps 1 to 6, or see Alternate Protocol 1, steps 1 to 5).
2. Remove the [^{35}S]methionine working solution, wash once with 10 ml of 37°C chase medium, and add 10 ml of 37°C chase medium.

   Rapid termination of the labeling reaction can be achieved by adding two times the volume of chase medium containing excess unlabeled methionine (15 mg/liter) directly to the labeling mixture.

   Final concentration of cells in suspension should be 2 × 10^6 cells/ml for chases ≤2 hr, or 0.5 × 10^6 cells/ml for chases >2 hr. For adherent cells, add 10 ml/100-mm dish.
3. Incubate for the desired time at 37°C. Incubate cell suspensions with rotation in tightly capped tubes. Incubate adherent cells in a CO_2 incubator.

4a. *For cells in suspension:* Collect cells by centrifuging 5 min at 300 × *g*, 4°C.

   The supernatant can be discarded or can be collected for analysis of proteins that are secreted or shed into the medium.

4b. *For adherent cells:* Scrape off adherent cells and transfer to 15-ml centrifuge tubes. Centrifuge 5 min at 300 × *g*, 4°C, and either save or discard the supernatant as in step 4a.

5. *Optional:* Determine amount of label incorporation by trichloroacetic acid (TCA) precipitation (see Support Protocol 1).

   Labeled cells are now ready for the desired processing and analysis (see Basic Protocol, step 8 annotation, if cells are not to be used immediately).

LONG-TERM LABELING OF CELLS WITH [^{35}S]METHIONINE

ALTERNATE PROTOCOL 3

Long-term labeling refers to continuous metabolic labeling of cells for periods of 6 to 32 hr. Long-term labeling is particularly advantageous when studying proteins that are synthesized at low rates. It is also used to accumulate mature labeled proteins, rather than biosynthetic precursors, for characterization of their properties. Steady-state labeling is a form of long-term labeling in which cells are incubated with the radiolabeled amino acid until the rates of synthesis and degradation of the radiolabeled proteins are equal. Steady-state labeling allows calculation of the stoichiometry of subunits within a protein complex, provided that the primary structure of the subunits is known. In these procedures, unlabeled methionine is added to the medium to maintain cell viability and to sustain incorporation of label for the duration of the experiment. The amount of unlabeled methionine added depends on factors such as the length of the labeling period and the cell density. Media containing between 5% and 20% the normal amount of unlabeled methionine are generally used. The conditions described below are suitable for overnight (~16 hr) labeling of cells in suspension or adherent cells.

BOSTON CENTRAL UNIVERSITY LIBRARY

Additional Materials (also see Basic Protocol and Alternate Protocol 1)

Long-term labeling medium (see recipe), warmed to 37°C
75-cm^2 tissue culture flask

1. Prepare a 0.02 to 0.1 mCi/ml [^{35}S]methionine working solution in prewarmed (37°C) long-term labeling medium (see Basic Protocol, step 1).

For cell suspensions:

2a. Prepare and wash cells once with prewarmed long-term labeling medium (see Basic Protocol, steps 2 and 3).

3a. Resuspend 0.5–2 × 10^7 cells in 25 ml of 0.02 to 0.1 mCi/ml [^{35}S]methionine working solution and transfer to a 75-cm^2 tissue culture flask.

For adherent cells:

2b. Grow 0.5–2 × 10^7 adherent cells in a 75-cm^2 tissue culture flask (80% to 90% confluency) in a CO_2 incubator. Wash once with prewarmed long-term labeling medium (see Alternate Protocol 1, step 3).

3b. Add 25 ml of 0.02 to 0.1 mCi/ml [^{35}S]methionine working solution to each 75-cm^2 flask.

4. Tighten caps to prevent release of volatile ^{35}S-labeled compounds. Incubate 16 hr in a CO_2 incubator.

5. Wash cells and determine incorporation (see Basic Protocol, steps 7 and 8, or Alternate Protocol 1, steps 6 to 9).

Labeled cells are now ready for the desired processing and analysis (see Basic Protocol, step 8 annotation, if cells are not to be used immediately).

ALTERNATE PROTOCOL 4

METABOLIC LABELING WITH OTHER RADIOLABELED AMINO ACIDS

In some instances, it may be necessary to label proteins with radiolabeled amino acids other than [^{35}S]methionine—e.g., when the proteins have a low methionine content or have no methionine residues at all. In these cases, the best choices are [^{35}S]cysteine or [^{3}H]leucine.

Cysteine residues are more abundant in proteins than methionine residues (3.4% versus 1.8%; Table 3.7.1), although cysteine is less stable. Formulations of [^{35}S]cysteine that have high specific activity (>800 Ci/mmol) can be obtained from several companies. Leucine has the advantage of being the most frequent amino acid in proteins (10.4%; Table 3.7.1) and specific activities of [^{3}H]leucine are the highest among ^{3}H-labeled amino acids (up to 190 Ci/mmol). If proteins are known to be rich in a particular amino acid or if special methods are to be performed (e.g., radiochemical sequencing or multiple labeling), ^{3}H-labeled amino acids other than [^{3}H]leucine can be used.

Label cells with these amino acids as described for [^{35}S]methionine in the previous protocols. Substitute [^{35}S]cysteine or ^{3}H-labeled amino acids in the labeling medium. Use labeling medium lacking cysteine or any other respective amino acid.

CAUTION: Solutions containing [^{35}S]cysteine release volatile ^{35}S-labeled compounds (refer to Safety Precautions).

RCU IASI CENTRAL UNIVERSITY LIBRARY

TCA PRECIPITATION TO DETERMINE LABEL INCORPORATION

In metabolic labeling experiments, it is often useful to monitor the incorporation of radioactivity into total cellular proteins. This can easily be achieved by precipitation with trichloroacetic acid (TCA) using BSA as a carrier protein. This protocol can be used at the end of the labeling procedures in each protocol.

Materials

Labeled cell suspension (see Basic Protocol or Alternate Protocols 1 to 4)
BSA/NaN_3: 1 mg/ml BSA containing 0.02% (w/v) sodium azide (NaN_3)
10% (w/v) TCA solution (see recipe), ice cold
Ethanol

Filtration apparatus attached to a vacuum line
2.5-cm glass microfiber filter disks (Whatman GF/C)

CAUTION: TCA is extremely caustic. Protect eyes and avoid contact with skin when preparing and handling TCA solutions.

1. Add 10 to 20 µl of a labeled cell suspension to 0.1 ml BSA/NaN_3. Place on ice.
2. Add 1 ml ice-cold 10% (w/v) TCA solution. Vortex vigorously and incubate 30 min on ice.
3. Filter the suspension onto 2.5-cm glass microfiber filter disks in a filtration apparatus under vacuum.
4. Wash the disks twice with 5 ml ice-cold 10% (w/v) TCA solution and twice with ethanol. Air dry 30 min.

   CAUTION: *The wash fluids should be handled as mixed chemical/radioactive waste—follow applicable safety regulations for disposal (see APPENDIX 2B).*

5. Spot the same volume of the radiolabeled cell suspension used in step 1 (10 to 20 µl) on a glass microfiber disk. Air dry.

   This disk will be used to measure the total amount of radiolabeled amino acid in the cell suspension.

6. Transfer disks from steps 4 and 5 to 20-ml scintillation vials, add 5 ml scintillation fluid, and measure the radioactivity in a scintillation counter.
7. Calculate the ratio of TCA-precipitable label to total radioactivity (i.e., the ratio of sample radioactivity in step 4 to the total radioactivity in step 5).

REAGENTS AND SOLUTIONS

Use deionized or distilled water in all recipes and protocol steps. For common stock solutions, see APPENDIX 2E; for suppliers, see SUPPLIERS APPENDIX.

NOTE: Use sterile tissue culture technique to prepare these reagents.

Chase medium

Pulse-labeling medium (see recipe) containing 15 mg/liter unlabeled methionine or equivalent excess amount of other amino acid used for radiolabeling. Store up to 2 weeks at 4°C.

Long-term labeling medium (90% methionine-free medium)

Mix 9 vol pulse-labeling medium (see recipe), lacking methionine or other appropriate amino acid, with 1 vol chase medium (see recipe) containing the same amino acid. Store up to 2 weeks at 4°C.

BOWMAN CENTRAL UNIVERSITY LIBRARY

Pulse-labeling medium

Use supplemented Dulbecco's modified Eagle medium (DMEM; see *APPENDIX 3C* but omit nonessential amino acids) or RPMI 1640, each lacking methionine or other specific amino acid, but containing 10% (v/v) FBS (dialyzed overnight against saline solution to remove unlabeled amino acids). Add 25 mM HEPES buffer (with pH adjusted to 7.4 with NaOH). Store up to 2 weeks at 4°C.

The amino acid used to label cells is omitted from this medium (e.g., if [^{35}S]methionine is employed, methionine-free DMEM or RPMI 1640 must be used). Specific amino acid–free media can be obtained from several tissue culture medium suppliers, or can be prepared (see APPENDIX 3C) from amino acid–free medium by adding individual amino acid components, omitting the one that will be used to label. A kit for the preparation of such media is available (Select-Amine from Life Technologies).

Trichloroacetic acid (TCA) solution, 10% (w/v)

Prepare a 100% (w/v) TCA stock solution by dissolving the entire contents of a newly opened TCA bottle in water (e.g., dissolve the contents of a 500-g bottle of TCA in sufficient water to yield a final volume of 500 ml). Store up to 1 year at 4°C. Prepare 10% (w/v) TCA by dilution and store up to 3 months at 4°C.

CAUTION: *TCA is extremely caustic. Protect eyes and avoid contact with skin when preparing and handling TCA solutions.*

COMMENTARY

Background Information

Metabolic labeling of cellular proteins is achieved by placing cells in a nutritional medium containing all components necessary for growth of cells in culture, except for one amino acid that is substituted by its radiolabeled form. The radiolabeled amino acids are transported across the plasma membrane by carrier-mediated systems and, once in the cytosol, are loaded onto tRNA molecules before being incorporated into newly synthesized proteins.

Because metabolic labeling techniques use the metabolic machinery of the cell to incorporate radiolabeled amino acids, there are limitations on the type of radiolabeled amino acids that can be employed. The list of potential precursors is restricted to L-amino acids normally found in proteins, in which one or more atoms are substituted by a radioisotope (Table 3.7.1). Sulfuric amino acids, such as methionine and cysteine, are conveniently labeled with ^{35}S. Most other amino acids can be obtained labeled with ^{3}H.

Critical Parameters

The protocols in this unit should be considered as models from which more specific methods can be designed. The conditions described here have been optimized for radiolabeling proteins that are expressed at low to moderate levels (10^4 to 10^5 copies per cell) and assume that the labeled cells will be used for immunoprecipitation (*UNIT 3.8*). This level of expression is characteristic of most endogenous membrane proteins, lumenal organellar proteins, signal transduction proteins, and transcription factors. More abundant proteins, such as cytoskeletal proteins or proteins expressed by infection or transfection, can be labeled with less radiolabeled amino acid and/or fewer cells. The choice of a particular labeling protocol and its modification will be aided by careful consideration of a number of parameters that influence the incorporation of radiolabeled amino acids into proteins, as discussed below.

Selection of amino acid label

Purified [^{35}S]methionine of high specific activity (>800 Ci/mmol) can be obtained from several suppliers of radiolabeled amino acids. Protein hydrolyzates of *Escherichia coli* grown in the presence of $[^{35}SO_4]^{2-}$ (e.g., Tran^{35}S-label from ICN Biomedicals or Expre^{35}S^{35}S from NEN Life Sciences) can be used as substitutes for [^{35}S]methionine in metabolic labeling techniques. These preparations contain ^{35}S distributed among several different compounds. In a typical batch, ~70% of the radioactivity will be present in the form of [^{35}S]methionine and ~15% as [^{35}S]cysteine; the remainder is other ^{35}S-labeled compounds. Labeling with these radioactive protein hydrolyzates in methionine-free medium will result in incorporation of label only in methionine residues; use of

PCU IASRI CENTRAL UNIVERSITY LIBRARY

methionine- and cysteine-free medium will result in labeling of both methionine and cysteine residues.

Purified [^{35}S]methionine should be used whenever certainty of labeling with only [^{35}S]methionine is required. Another reason for using purified [^{35}S]methionine is that it tends to be more stable and emit less volatile decomposition products than ^{35}S-labeled protein hydrolyzates. In most cases, however, the relatively inexpensive radioactive protein hydrolyzates (about one-third the cost of [^{35}S]methionine) can be used instead of purified [^{35}S]methionine. [^{35}S]methionine preparations should be stored frozen at −80°C. Under these conditions, they are stable for at least 1 month; the half-life of ^{35}S is 88 days.

For proteins with one or no methionine residues but several cysteine residues, labeling with [^{35}S]cysteine (available with specific activities >800 Ci/mmol) is a good option. ^{35}S-labeled protein hydrolyzates are not good sources of [^{35}S]cysteine for radiolabeling because only ~15% of the ^{35}S-labeled compounds are [^{35}S]cysteine.

Purified [^{3}H]leucine (available with specific activities of up to 190 Ci/mmol) is a good alternative to ^{35}S-labeled amino acids. The half-life of ^{3}H is ~12 years. The specific activities of other ^{3}H-labeled amino acids range between 5 and 140 Ci/mmol (Table 3.7.1). Several problems can arise when using certain ^{3}H-labeled amino acids due to their participation in metabolic pathways. The following problems must be considered when using tritiated amino acids for metabolic labeling of proteins.

Nonessential versus essential amino acids. Cells are able to synthesize nonessential amino acids from other compounds. If the radiolabeled amino acids used are nonessential, their specific activity will be reduced by dilution with the endogenously synthesized amino acids. Therefore, essential amino acids (E in Table 3.7.1) should be favored for metabolic labeling.

Transamination. The α-amino groups of many amino acids can be removed in reactions catalyzed by transaminases (T in Table 3.7.1). Deamination of the radiolabeled amino acids can be prevented by addition of the transaminase inhibitor (aminooxy)acetic acid during starvation and labeling of the cells (Coligan et al., 1983).

Interconversion. Certain radiolabeled amino acids can be converted by cells into other amino acids (I in Table 3.7.1). This problem is of particular importance when one is attempting to determine the amino acid composition or sequence of radiolabeled proteins.

Labeling time

The experimental purpose, the turnover rate of the protein of interest, and the viability of the cells should all be considered when determining the length of time for labeling. If the purpose of the experiment is to identify or characterize a protein precursor, pulse-labeling (10 to 30 min) must be used (see Basic Protocol and Alternate Protocol 1). If the protein of interest has a low turnover rate or if it is necessary to accumulate a labeled mature product, a protocol for long-term labeling (6 to 32 hr) is more appropriate (see Alternate Protocol 3). If the biosynthesis, post-translational modification, intracellular transport, or fate of newly synthesized proteins is being analyzed, a pulse-chase protocol should be used (see Alternate Protocol 2).

The turnover rate of the protein of interest is an important parameter to be considered when determining the labeling time. Proteins with a high turnover rate are optimally labeled for short times. Longer times will result in increased labeling of other cellular proteins, causing a decrease in the relative abundance of the labeled protein of interest in the cell lysate. This could result in increased detection of nonspecific proteins in immunoprecipitates (see *UNIT 3.8*). Conversely, proteins that turn over slowly should be labeled for longer times.

Incorporation of radiolabeled amino acids into proteins is directly proportional to the labeling time for a certain period, after which it tends to plateau. When all the limiting amino acid is consumed, protein synthesis ceases. The length of the initial phase of linear incorporation will vary with the concentration of the labeling amino acid and the density and metabolic activity of the cells.

Concentration and specific activity of the radiolabeled amino acid

Because radiolabeled amino acids are used in limiting amounts, their incorporation into proteins is directly proportional to their concentration in the labeling medium. If very short pulses are required, the concentration of labeled amino acid can be increased to compensate for the shorter labeling time. The incorporation of radiolabeled amino acids is also directly proportional to their specific activity. Addition of unlabeled amino acids, as is required in long-term labeling protocols, will result in reduced incorporation over short periods.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

B. C. U. „M. EMINESCU" IAŞI
CHIMIE

Cell density

At low cell densities, the amount of labeled protein synthesized is directly proportional to the cell concentration. At high densities, however, incorporation will increase nonlinearly. Very concentrated cell samples (>5 × 10^7 cells/ml) can only be labeled for short periods (≤5 min) as rapid loss of metabolic activity and cell viability will occur due to acidification of the medium and accumulation of toxic metabolites.

Conditions for very short pulses

Very short pulses (2 to 10 min) are required to study post-translational modifications that occur shortly after synthesis. These include folding, disulfide bond formation, and early carbohydrate modifications of newly synthesized proteins. Proteins that are rapidly degraded after synthesis are also best studied with very short pulses. The protocol for very short pulses is similar to the Basic Protocol for pulse-labeling, with the following modifications: (1) the pulse-labeling medium contains higher concentration of radiolabeled amino acid (up to 1 mCi/ml), (2) labeling is stopped by addition of ice-cold PBS containing 20 mM freshly prepared *N*-ethylmaleimide (NEM) to prevent oxidation of free sulfhydryls, and (3) if a chase is necessary, 1 mM cycloheximide is added to the chase medium to quickly stop the elongation of nascent polypeptide chains. For additional details on very short pulses, see Braakman et al. (1991).

Temperature and pH

Unless otherwise required for special conditions (e.g., heat shock, temperature-sensitive mutants), metabolic labeling should be performed at 37°C. For this reason, it is important that the labeling medium be warmed to 37°C before adding it to the cells. A dramatic reduction in incorporation occurs at room temperature. It is also important that the pH of the labeling medium be ~7.4.

Anticipated Results

A typical incorporation of labeled amino acid precursor after a 30-min pulse under the conditions described in this unit (see Basic Protocol and Alternate Protocols 1 and 2) is 5% to 20%. In the case of long-term labeling, the incorporation typically reaches 30% to 60%. If the labeled cells are used for immunoprecipitation (*UNIT 3.8*), followed by SDS-PAGE (*UNIT 10.1*) and autoradiography (*UNIT 10.11*), specific bands should be visible within 2 hr to 2 months of exposure.

Time Considerations

It takes 1 to 2 hr to prepare cells and materials for labeling. The actual labeling time depends upon the protocol chosen—pulse-labeling takes 10 to 30 min and long-term labeling takes 6 to 32 hr. Washing and processing cells may take an additional 1.5 hr.

5. Remove 2-µl aliquots of the supernatants and add 28 µl SDS-PAGE sample buffer. Analyze the samples by SDS-PAGE (*UNIT 10.1*) to determine the heat stability of the fusion protein and the minimum time of heat treatment required to obtain a good purification.

REAGENTS AND SOLUTIONS

Use deionized, distilled water in all recipes and protocol steps. For common stock solutions, see APPENDIX 2E; for suppliers, see SUPPLIERS APPENDIX.

Casamino Acids (CAA), 2% (w/v)

20 g Casamino Acids (Difco-certified)
H_2O to 1 liter
Autoclave or filter sterilize through a 0.45-µm filter
Store ≤2 months at room temperature

Do not use technical-grade Casamino Acids because it has a higher NaCl content.

CAA/glycerol/ampicillin 100 medium

800 ml 2% (w/v) Casamino Acids (see recipe; 1.6% final)
100 ml 10× M9 salts (see recipe; 1× final)
100 ml 10% (v/v) glycerol (sterile; 1% final)
1 ml 1 M $MgSO_4$ (sterile; 1 mM final)
0.1 ml 1 M $CaCl_2$ (sterile; 0.1 mM final)
1 ml 2% (w/v) vitamin B1 (sterile; 0.002% final)
10 ml 10 mg/ml ampicillin (sterile; 100 µg/ml final)
Prepare fresh

IMC medium

200 ml 2% (w/v) Casamino Acids (see recipe; 0.4% final)
100 ml 10× M9 salts (see recipe; 1× final)
40 ml 20% (w/v) glucose (sterile; 0.5% final)
1 ml 1 M $MgSO_4$ (sterile; 1 mM final)
0.1 ml 1 M $CaCl_2$ (sterile; 0.1 mM final)
1 ml 2% (w/v) vitamin B1 (sterile; 0.002% final)
658 ml glass-distilled H_2O (sterile)
10 ml 10 mg/ml ampicillin (sterile; optional; 100 µg/ml final)
Use fresh

IMC plates

15 g agar [Difco; 1.5% (w/v)]
4 g Casamino Acids [Difco-certified; 0.4% (w/v)]
858 ml glass-distilled H_2O (sterile)
Autoclave 30 min
Cool in a 50°C water bath
100 ml 10× M9 salts (see recipe; 1× final)
40 ml 20% (w/v) glucose (sterile; 0.5% final)
1 ml 1 M $MgSO_4$ (sterile; 1 mM final)
0.1 ml 1 M $CaCl_2$ (sterile; 0.1 mM final)
1 ml 2% (w/v) vitamin B1 (sterile; 0.002% final)
10 ml 10 mg/ml ampicillin (sterile; optional; 100 µg/ml final)
Mix well and pour into petri plates
Store ≤1 month at 4°C

BCU MAIN CENTRAL UNIVERSITY LIBRARY

M9 salts, 10×

60 g Na_2HPO_4 (0.42 M)
30 g KH_2PO_4 (0.24 M)
5 g NaCl (0.09 M)
10 g NH_4Cl (0.19 M)
H_2O to 1 liter
Adjust pH to 7.4 with NaOH
Autoclave or filter sterilize through a 0.45-μm filter
Store ≤6 months at room temperature

SDS-PAGE sample buffer

15% (v/v) glycerol
0.125 M Tris·Cl, pH 6.8 (*APPENDIX 2E*)
5 mM Na_2EDTA
2% (w/v) SDS
0.1% (w/v) bromphenol blue
1% (v/v) 2-mercaptoethanol (2-ME; add immediately before use)
Store indefinitely at room temperature

Tryptophan, 10 mg/ml

Heat 500 ml glass-distilled H_2O to 80°C. Stir in 5 g L-tryptophan until dissolved. Filter sterilize the solution through a 0.45 μm filter and store ≤6 months in the dark at 4°C.

COMMENTARY

Background Information

Two significant problems plague researchers who hope to express heterologous proteins in *Escherichia coli*: inefficient initiation of translation of many eukaryotic mRNA sequences on bacterial ribosomes (Stormo et al., 1982), and proteins that often form insoluble aggregates, called inclusion bodies, that are composed of misfolded or denatured proteins (Mitraki and King, 1989). Although successful protocols for refolding eukaryotic proteins from inclusion bodies can be developed, the process is always uncertain and usually time-consuming; in most instances it is preferable to prevent inclusion-body formation in the first place. The use of *trxA* fusions provides a solution to both problems.

Inefficient initiation of translation of eukaryotic messages in *E. coli* can often be improved by modifying sequences at the 5′ end of the gene. A more reliable technique that avoids the problem entirely is to use a gene-fusion strategy in which the gene of interest is linked in-frame to the 3′ end of a highly translated partner gene. In this case protein synthesis always initiates on the same efficiently translated fusion-partner mRNA, thus ensuring high-level expression. Some earlier gene-fusion expression systems, for example the *trpE* and *lacZ* systems, offer very reliable ways of producing large quantities of any desired eukaryotic protein. However, these gene-fusion systems still suffer from the pervasive inclusion-body problem. They are thus mainly useful for the production of antigens, rather than correctly folded, biologically active proteins. More recently the maltose binding protein (MBP; Riggs, 1994; *UNIT 5.1*) and glutathione-*S*-transferase (GST) gene fusion expression systems (see *UNIT 6.6*) have proven more successful in producing soluble fusion proteins; these systems retain the translation advantage of the earlier fusion systems. Apart from the obvious advantages in making a correctly folded product, the synthesis of soluble fusion proteins also allows for the development of generic purification schemes based on some unique property of the fusion partner.

Why would any particular eukaryotic protein produced in the *E. coli* cytoplasm be more soluble when it is linked to a fusion partner than it would be by itself? It is likely that physical properties of the fusion-partner protein are important, with efficient self-folding and high solubility being useful in this role. It is possible that some good fusion partners (proteins that fold efficiently and are highly soluble), by virtue of their desirable physical qualities, are able to keep folding intermediates of linked heterologous proteins in solution long enough for

CHAPTER 10
Electrophoresis

INTRODUCTION

Electrophoresis of protein samples in polyacrylamide gels is an indispensable analytical and, in some cases, preparative tool for the protein scientist. Electrophoresis can be used to separate and compare complex protein mixtures, evaluate purity of a protein during the course of its isolation, and provide estimates of physical characteristics such as subunit composition, isoelectric point, size, and charge.

Each type of electrophoretic separation can be conducted in a variety of gel sizes ranging from microgels (e.g., Phast gels from Hoefer Pharmacia) only slightly larger than a postage stamp to giant gels much larger than this page (Garrels, 1979; Young et al., 1983). In general, the time required to electrophorese, stain, and destain small gels is very short, and a minimal amount of sample is consumed. In contrast, larger gels consume more reagents, sample, and time, but provide increased resolution. Small gels are therefore recommended for rapid screening, and larger gels are indicated when maximum resolution is required, as in analysis of complex mixtures or samples containing very similar components.

The most common one-dimensional gel methods utilize the detergent sodium dodecyl sulfate (SDS) to solubilize, denature, and impart a strong negative charge to proteins (*UNIT 10.1*). Although many one-dimensional SDS gel methods have been published over the past 30 years, the single most widely used method is that initially described by Laemmli (1970). SDS-based gel separations are very robust as most, but not all, proteins are readily solubilized in SDS solutions. Most proteins bind a uniform amount of SDS per microgram of protein, which imparts a uniform charge density per unit mass to provide a separation based on the mass of the polypeptide chain.

An alternative one-dimensional separation methodology is based on the protein's isoelectric point and is usually performed in the presence of denaturants such as urea (*UNIT 10.2*). Like one-dimensional SDS gel separations, this denaturing isoelectric focusing method is capable of separating a large number of components in a single dimension. A third one-dimensional method uses native conditions to separate proteins based on intrinsic charge (*UNIT 10.3*). Although this method has less resolving power than the previous two methods, it can be particularly useful for associating a specific electrophoretically separated component with a biological activity, since no denaturants are used.

Two-dimensional electrophoresis (*UNIT 10.4*) involves the orthogonal combination of two different electrophoretic methods. Any two electrophoresis techniques can be combined in this manner to produce useful separations. The most common two-dimensional approach combines two individually high-resolution methods, consisting of isoelectric focusing (*UNIT 10.2*) followed by SDS gel electrophoresis (*UNIT 10.1*). Each of these methods is individually capable of resolving up to about 100 protein bands; when the two are combined, more than 1,000 proteins can be separated on a single two-dimensional gel (O'Farrell, 1975; Garrels, 1979). Hence this method can be used to analyze and compare complex protein mixtures, including whole-cell or tissue extracts. One important application of two-dimensional gels is the systematic analysis and quantitative comparison of whole-cell or tissue extracts for the study of the proteome, or complete protein profile, of

the cell or tissue. In recent years a growing emphasis has been focused on such studies, particularly for organisms whose complete genome sequence has been determined. Other applications of two-dimensional electrophoresis include assessment of the purity and homogeneity of a purified protein, including recombinant proteins (Chapter 7), and evaluation of some post-translational modifications (Chapters 12 and 13).

After electrophoretic separation, proteins are usually detected using general protein staining methods, such as Coomassie blue staining or the more sensitive silver staining. These staining methods "fix" the proteins in the gel matrix by either chemical cross-linking or denaturation to prevent subsequent diffusion of the protein bands (*UNIT 10.5*). When proteins are to be eluted or extracted from the gels for subsequent analyses, however, fixation-based stains should usually be avoided. In these cases, methods for protein detection without fixation should be used (*UNIT 10.6*) when it is necessary to stain a gel to locate the protein of interest.

A useful method of isolating proteins from gels for subsequent analysis involves electroblotting onto an inert support, such as polyvinylidene difluoride (PVDF) membranes (*UNIT 10.7*). As a result of the versatility of PVDF membranes, electroblotting has largely replaced electroelution as the method of choice for isolating proteins from most types of polyacrylamide gels (LeGendre and Matsudaira, 1988). PVDF membranes have very high protein binding capacities, good handling characteristics when either dry or wet, and are highly chemically inert. Hence they are compatible with many methods for subsequent analysis, including amino acid analysis, in situ chemical modification, in situ protease digestion, and N-terminal sequence analysis (Chapter 11). A wide range of general protein stains exist that are compatible with most blotting membranes (*UNIT 10.8*). Alternatively, radiolabeled proteins can be detected by autoradiography either in the gel or after transfer to a PVDF membrane (*UNIT 10.11*). The latter is normally preferable; as long as the proteins of interest are electrotransferred in high yield, autoradiography signals of weak β emitters such as ^{14}C or ^{35}S are usually higher on electroblotted membranes than in dried gels (even when fluorophores are impregnated in the gel), because the protein is primarily located on the surface of the membrane that was in contact with the gel during electroblotting. Historically, autoradiography was performed using medical X-ray films. More recently, a relatively wide range of commercially available autoradiography films and exposure methods have been developed that provide superior contrast and higher sensitivity for specific isotopes (*UNIT 10.11*).

The dimensional stability and chemical resistance of PVDF membranes provides an optimal medium for combining multiple detection methods, either sequentially on the same membrane, or on parallel lanes that can be reassembled after different detection methods have been performed. For example, sets of lanes containing replicate samples can be run on a single gel separated by prestained standards, which are used as guides to cut the resulting membrane. Each lane set can be subjected to different detection methods such as protein staining and immunoblotting with different antibodies (*UNIT 10.10*). The analyzed membranes can then be precisely reassembled to determine the relationships between bands detected by different methods. As there is no shrinkage or swelling of the membrane, this approach is particularly valuable for detecting slight differences in migration between components detected by different methods.

An approach that has recently emerged as a useful analytical method for separating peptides and, to a more limited extent, proteins is capillary electrophoresis (CE; *UNIT 10.9*). CE protocols have also been developed for preparative peptide isolation in adequate amounts for subsequent high sensitivity measurements such as micro-sequencing (Chapter 11) and mass spectrometry (Chapter 16). CE employs a fused-silica capillary column that may contain either free solution or a fluid matrix. One of CE's limitations for protein

BCU IAS/CENTRAL UNIVERSITY LIBRARY

and peptide separations is the tendency of these molecules to interact with silanol groups on the capillary tubing surface. As described in *UNIT 10.9*, these interactions can be minimized through the use of coated capillaries, a separation pH several units above the protein pI, or buffer additives that minimize interactions with the silica walls. An interesting alternative approach is separation of proteins and peptides using capillary zone electrophoresis (CZE) in acidic amphoteric buffers (*UNIT 10.13*). The low conductivity of these buffers permits higher voltages to be used, resulting in faster separations, and the low pH minimizes ionization of silanol groups on underivatized capillaries. In this mode, nearly all proteins and peptides have strong positive charges and high mobilities. In contrast to the relatively simple equipment requirements of polyacrylamide-based electrophoretic methods, commercial CE instruments are similar in complexity and expense to high-performance liquid chromatography (HPLC) instruments, due to the necessity for a high-voltage supply, a high-performance cooling system, and a very sensitive detector. Because CE separates components by charge rather than by hydrophobicity as in reversed-phase HPLC, it is a highly useful orthogonal separation method that is frequently used to complement HPLC peptide separation strategies. Compared with polyacrylamide methods, CE offers much higher resolution, flexibility, sensitivity, and speed for separating peptides (<6 kDa), whereas polyacrylamide methods are more generally applicable for protein separations.

Documentation of gel electrophoresis results for either archival or publication purposes historically used primarily silver halide–based photography. In recent years, the availability of economical hardware and software for capturing, storing, and analyzing digital images has led to the replacement of photography by digital analysis as the preferred documentation method (*UNIT 10.12*). Advantages of digital-based methods include more convenient storage and retrieval, inexpensive and rapid production of backup or additional copies, facile manipulation such as resizing and inserting into reports, and rapid data distribution to colleagues over the Internet. Digital processing of electrophoretic results is particularly essential for comparing large numbers of gels, developing databases of gel patterns and related information, and performing quantitative comparisons such as proteome studies utilizing two-dimensional gels.

CHAPTER 16
Mass Spectrometry

INTRODUCTION

From the point of view of protein scientists, in the course of the 1990s mass spectrometry (MS) has developed from a fairly exotic technique practiced in only a handful of laboratories into a routine, essential tool for protein characterization. MS is complementary to other protein and peptide analysis methods such as protein sequencing, amino acid analysis, and high-performance liquid chromatography (HPLC) peptide mapping (Chapter 11). It is particularly useful for identifying post-translational modifications (Chapters 12 to 14), which are often quite difficult to distinguish by other methods. To some extent, MS is beginning to replace alternative methods such as Edman sequencing as continuing advances in instruments, software, and user-friendliness improve the sensitivity and utility of MS methods.

A detailed discussion of peptide and protein MS analysis, including sample ionization methods, basic principles and parameters, and data interpretation, is presented in *UNIT 16.1*. The unit also lists numerous literature references that should be especially useful to scientists seeking more detailed information on specific MS-related issues.

A key advance in the application of MS for routine analysis of peptides and proteins has been the development of commercial instruments that employ matrix-assisted laser desorption/ionization (MALDI) techniques to transfer peptides and proteins efficiently into the gas phase for time-of-flight based mass measurements. This technique has multiple advantages compared with older techniques, including the instruments' relatively low cost and ease of operation, relatively good tolerance of nonvolatile buffer components, and ability to analyze heterogeneous samples as mixtures, since the ionization method predominantly produces a single charged species per sample component. A general discussion of MALDI-MS analysis of peptides is presented in *UNIT 16.2*, and *UNIT 16.3* provides specific protocols for analysis of both peptides and proteins, with emphasis on sample preparation.

A frequent research question in biology is the correlation of observed function with the proteins responsible. MS-based methods have emerged as the most sensitive, rapid, and economical method for identifying proteins. The simplest approach is MALDI-MS fingerprint mapping following in-gel protease digestion of the protein of interest (*UNIT 16.4*). The observed peptide masses are used to search sequence databases over the Internet (*UNIT 16.5*) using one of several alternative algorithms. This method works best when the protein of interest is expected to be found in an available sequence database—i.e., when the complete genome of the species from which the protein was isolated has been sequenced. When the database contains only related, but nonidentical, proteins, or when the results of the fingerprint mapping search are ambiguous, partial sequence information is generally required to identify homologous proteins or to search expressed-sequence tag (EST) databases. Such partial sequence information can be obtained on a MALDI spectrometer either using fragmentation induced within the mass analyzer (*UNIT 16.6*) or via exopeptidase digestion of samples on the MS sample target (*UNIT 16.7*).

The other common mass analysis method for biomolecules is electrospray ionization (ESI)-MS (*UNIT 16.1*). In recent years, the cost of ESI-based instruments has decreased and

BOJANIC CENTRAL UNIVERSITY LIBRARY

they have become more sensitive and user friendly. Triple-quadrupole or ion-trap instruments with ESI interfaces are particularly well suited to tandem mass spectrometry (MS-MS) experiments, in which an initial mass measurement is followed by fragmentation of a target peptide and reanalysis of fragment mass spectra. ESI-MS is much less tolerant of salts and buffers than MALDI-MS, and samples are typically introduced by interfacing an HPLC instrument using a reversed-phase column on the front end of the mass analyzer. This serves both to clean up the sample and to separate components prior to introduction of sample into the mass analyzer. When capillary or nanocapillary HPLC columns are used without stream splitting, very high sensitivities can be obtained. Future units will detail the use of ESI instruments for protein and peptide characterization, and protein identifications either using MS-MS data directly or using de novo sequence interpretation of MS-MS data.

CHAPTER 18
Preparation and Handling of Peptides

INTRODUCTION

An important component of the armamentarium of modern protein scientists is the ability to design and construct peptides of almost any sequence. Peptides may be employed for a wide range of applications, including as substrates for kinases, proteases, or glycosidases, or as antigens to produce antisera that may recognize a protein containing that sequence. Peptides also have many biological functions on their own, interacting with receptors to stimulate changes in cellular function, or altering the interactions between cells, for example.

Chemists developed the means to synthesize peptides early in this century (*UNIT 18.1*). The ability to create a molecule that possessed biological activity by organic synthesis is certainly a milestone in our science. For many years, however, peptide synthesis was practiced only by highly skilled and dedicated individuals, and the lengthy time required to obtain even simple peptides limited their use as reagents for biological experiments. Difficulties in purification effectively eliminated the study of complex peptides of more than 5 to 10 amino acids.

Several developments have revolutionized this field, fortunately, and they have brought peptide science into the realm of standard biological techniques available to many scientists. First was the development of solid-phase methods by Bruce Merrifield and subsequent improvements in the reagents available for synthesis that are detailed in *UNIT 18.1*. Second was the design and construction of automated instruments to perform the repetitive steps of the solid-phase methodology, culminating in the 1980s with instruments that provided nearly global accessibility to synthetic peptides of ever increasing length.

Another advance was the optimization of reversed-phase HPLC as a separation method for the rapid purification and analysis of synthetic peptides (*UNIT 11.6*). A future unit in this chapter will focus on medium-to-large scale peptide purification by HPLC methods. In addition, recent advances in mass spectroscopy (Chapter 16) have provided another critical analytical tool to verify the products of synthesis.

A convenient, low-cost method for creating large numbers of related peptides or for assembly of a set of peptides that together span an entire protein to search for the epitope recognized by an antibody that binds to the full-length protein is provided by the synthesis of peptides on a multipin apparatus (*UNIT 18.2*).

Frequently, genomic studies lead to the discovery of an open reading frame (ORF), predicting a protein sequence that might have an activity of interest. One step that could follow would be the generation of an antibody to use as a reagent to identify the protein product of the gene in a sample isolated from the organism under study. A small peptide of 10 to 15 amino acids can frequently be used as an antigen to stimulate antiserum production. This requires picking the best sequence out of an ORF of hundreds of amino acids and preparing the conjugate for injection into an animal for generation of the antiserum (*UNIT 18.3*).

As the procedures employed in solid-phase peptide synthesis have improved, researchers' desire to attempt the preparation of longer sequences has grown. Methods to ligate

BCU IRSI / CENTRAL UNIVERSITY LIBRARY

medium- to large-sized peptides together through defined chemistry are presented in *UNIT 18.4*. Success in this approach has opened the door to a variety of new synthetic objectives.

The chemistry and strategy utilized to prepare peptide dendrimers (*UNIT 18.5*) for use as immunogens, designed protein mimics, new reagents for drug discovery, or new biomaterials has been an outgrowth of solid-phase peptide synthesis. Methods for both Boc and Fmoc syntheses are described here. In addition, several procedures for the formation of cyclic peptides are presented, including derivatization of Lys and Cys residues.

Units planned for future expansion of this chapter will cover synthesis of derivatives such as phosphopeptides or other modification that can be done at the resin-bound stage, the reactions necessary to form disulfide bridges at the appropriate points in peptides, the creation of derivatives in which selective peptide bonds have been replaced to create inhibitors or to stabilize against degradation in biological systems, methods for storage and handling of peptides, specialized methods for different types of resins for solid-phase synthesis, the creation of peptide libraries by chemical or biological approaches, the chemistry necessary to achieve the coupling of difficult or hindered peptides, and methods for the assembly of peptides of 100 amino acid residues in a single, long synthesis.

COUPLING SYNTHETIC PEPTIDES TO A CARRIER PROTEIN USING A CARBODIIMIDE

ALTERNATE PROTOCOL 4

This procedure couples amino groups to carboxyl groups by way of activation of the carboxyl group with a water-soluble carbodiimide. Since the procedure is most easily performed in one step, peptides containing internal Asp, Glu, Lys, Tyr, or Cys residues should not be used. Also, in order to avoid making polymers of the peptide, the amino terminus should be blocked by acetylation during synthesis (see Basic Protocol 2). While this method has been used successfully, it is not considered to be the method of choice except in special situations.

Additional Materials (also see Basic Protocol 3)

1-ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC; Pierce), used fresh or stored desiccated and frozen
0.1 N HCl

NOTE: Buffers containing amino or carboxyl groups should not be used in this procedure. According to some reports, buffers containing phosphate groups should also be avoided. Water is the safest choice as a solvent.

1. Dissolve 5 mg synthetic peptide in 1 ml water.
2. Add 25 mg EDC and carefully adjust pH to 4.0 to 5.0 by adding small amounts of 0.1 N HCl. Allow to react for 5 to 10 min at room temperature with gentle mixing.

   pH paper suffices to monitor this adjustment.
3. Dissolve 5 mg KLH in 0.5 ml water and add to solution from step 2. React 2 hr at room temperature with gentle mixing.
4. Dialyze against 4 liters of water overnight at 4°C. Use immediately.

COUPLING SYNTHETIC PEPTIDES TO A CARRIER PROTEIN PHOTOCHEMICALLY

ALTERNATE PROTOCOL 5

Most synthetic peptides today are made with 9-fluorenylmethyloxycarbonyl (Fmoc) chemistry (see Fig. 18.1.1), and therefore the following protocol links the photoactive group to the free amino terminus of the peptide. An alternative approach if *t*-butyloxycarbonyl (Boc) chemistry is used is to link it to an ε-amino group of a terminal lysine (Gorka et al., 1989).

Additional Materials (see also Basic Protocol 3)

4-benzoyl benzoic acid (Sigma or Aldrich)
Quartz spectrophotometry cuvettes

1. Have the synthetic chemist who is making the peptide attach a benzoyl benzoic acid group to the amino terminus simply by treating the reagent as the terminal residue during normal synthesis.

   This blocks the amino terminus.
2. Dissolve 5 mg KLH in ~0.5 ml of 0.01 M sodium phosphate buffer, pH 7.5.
3. Add 2 mg of synthetic peptide containing the benzoyl benzoate adduct.
4. Place in a 1-cm quartz cuvette and irradiate with 366-nm light for 3 hr at a distance of 0.5 cm. Use immediately.

   The peptide can be used directly for immunization.

BCU IASI CENTRAL UNIVERSITY LIBRARY

REAGENTS AND SOLUTIONS

Use Milli-Q-purified water or equivalent for the preparation of all buffers. For common stock solutions, see APPENDIX 2E; for suppliers, see SUPPLIERS APPENDIX.

Cysteine standard stock solution

Dissolve 26.3 mg cysteine hydrochloride monohydrate in 100 ml of 0.1 M sodium phosphate, pH 8.0 (*APPENDIX 2E*). Prepare immediately before use.

Ellman's reagent solution

Dissolve 4 mg Ellman's reagent, 5,5′-dithio-bis-(2-nitrobenzoic acid) (Pierce), in 1 ml of 0.1 M sodium phosphate, pH 8.0. Prepare immediately before use.

Glutaraldehyde solution, 0.15%

Add 30 µl of 25% aqueous glutaraldehyde solution to 5 ml of 50 mM sodium borate buffer, pH 8.0 (pH adjusted with HCl). Prepare fresh and use immediately. If the glutaraldehyde precipitates, check the pH. It should not be above 8.0; a slightly lower pH can be used (pH 7 to 8).

CAUTION: *Glutaraldehyde is a sensitizing agent that should be handled in a hood and only according to the recommendations in the Material Safety Data Sheet. When mixing solutions or performing reactions, keep the container covered to prevent vapors from escaping into the atmosphere.*

Guanidine·HCl, 6 M

Dissolve 1 g guanidine·HCl in 1 ml of 0.05 M sodium phosphate, pH 7.0. Store up to several weeks at room temperature.

The resulting 1.8-ml solution should be ~0.025 M phosphate/6 M guanidine·HCl at pH 7.0.

COMMENTARY

Background Information

Synthetic peptides are linear arrays of amino acids that in most instances possess a random structure in solution. While it is not difficult to produce antipeptide antibodies, it does not necessarily follow that the antibodies will recognize a protein containing the same stretch of sequence found in the peptide. In order for this to occur, the amino acids in the protein must be oriented to the antibody in a way similar to that of the synthetic peptide. This generally requires three basic features of the protein: (1) that the stretch of sequence be exposed to solvent; (2) that the sequence be a continuous stretch of amino acids; and (3) that it not possess a higher-order structure that renders it unrecognizable by the antibody population.

The large number of model protein structures now available indicate that almost all of the ionized groups in water-soluble proteins are on the protein surface. Asp, Glu, Lys, and Arg residues, on the average, comprise 27% of the protein surface and only ~4% of the protein interior. The fraction of residues at least 95% buried range from 0.36 to 0.60 for nonpolar residues and 0.01 to 0.23 for polar residues. Only 1% of Arg and 3% of Lys residues fall into the 95% buried range (Creighton, 1993). Therefore, it is reasonable to expect solvent-exposed areas of proteins to display relatively high levels of polar and charged residues, particularly Arg and Lys.

Proteins display three kinds of secondary structure: α-helices, β-sheets, and turns or loops (see *UNIT 17.1*). Turns or loops generally connect elements of α-helices and β-sheets, and can either fit one of several rather strict motifs with recognizable hydrogen bonding patterns or be of a more extended, random nature. These turn or loop structures appear to be most useful for antibody production because they tend to be found on the surface of proteins connecting larger arrays of helices and sheets, and they consist of continuous stretches of amino acids. Although many amino acid residues in helices and sheets are also exposed at the surface, the regular geometry of amino acids contained within them makes them less suitable for this purpose. For instance, in β-sheet structures the side chain of each successive amino acid in the β-sheet strand points in the opposite direction to the ones immediately preceding and following it. Thus, even if the amino acid side chains are not predominantly buried in the interior of

BOU IASL CENTRAL UNIVERSITY LIBRARY

Synthesis and Application of Peptide Dendrimers As Protein Mimetics

Peptide dendrimers are branched polymers with peptides attached centrally to a template or core matrix. They are synthesized as defined dendritic structures. Their molecular weights increase geometrically as a function of generation branching of monomers. Usually, 2 to 16 peptidyl branches of the same or different sequences are used to form a peptide dendrimer. Architecturally, peptide dendrimers belong to the multichained, cascade-shaped polymer family. Thus, they contain multiple N- or C-terminal ends that can be exploited as a platform for multitasks. Such a molecular architecture is different from conventional polypeptides or proteins that contain a single unbranched contiguous structure with two terminal ends. Peptide dendrimers are also different from organic star-burst dendrimers, which are spherically shaped and often consist of >16 hyperbranched small organic monomers. However, the fundamental dendrimeric design consisting of monomers radiated from a center core is similar, conceptually, to the organic dendrimers.

Peptide dendrimers come in different forms and sizes. Their forms are determined by the templates and peptide structures while their sizes are determined by the numbers and lengths of peptide monomers. Although their sizes vary over a wide range from 3 to >100 kDa, most peptide dendrimers reported to date are in the range of 6 to 20 kDa.

A driving force in developing peptide dendrimers is the effort to mimic forms and functions of proteins. Thus far, peptide dendrimers have found applications in four active areas: (1) immunological applications as immunogens and antigens; (2) de novo design of artificial proteins; (3) protein mimetics as agonists and antagonists in drug discovery; and (4) new biopolymers and biomaterials. However, this unit will focus on the use of peptide dendrimers as protein mimetics.

The use of peptides to mimic a portion of a protein structure is a challenging and powerful tool in the discovery of new drugs. In native proteins, discontinuous bioactive peptide surfaces are held together in a particular conformation by the structural rigidity of the protein. One approach to mimicking the structural surface on the protein is to bring the potential peptide sequences together by assembling the peptide chains on a template as a peptide dendrimer. Recently, small peptides have been demonstrated to adopt well defined conformations when they are attached on a template (Schneider and Kelly, 1995). In the past 15 years, templates suitable for protein engineering have been developed. These templates are flexible dendrimeric peptides (Tam, 1988; Wrighton et al., 1997) and cyclic peptides (Mutter and Vuilleumier, 1989), as well as more rigid organic molecules (Unson et al., 1984; Sasaki and Kaiser, 1989).

In 1988, the multiple antigenic peptide (MAP) system was introduced in the authors' laboratory (Tam, 1988; Tam and Lu, 1989) as a novel approach to preparing peptide immunogens. The MAP consists of an inner core matrix built up of a large layer of Lys residues and a surface of peptide chains attached to the core matrix (Fig. 18.5.1). Because of its dendrimeric structure, MAP can be very useful as a template for assembling potential peptide surfaces. Furthermore, the effect of MAP on secondary structures has also been studied (Shao and Tam, 1995). These study results showed that the peptide dendrimer has an increased ordered helical structure, while the peptide monomer and the tetravalent lysinyl core matrix do not have any ordered structure. The synthetic schemes for preparing MAPs suitable for protein mimetics are the same as those for generating MAPs as peptide immunogens. In addition to the applications in immunology, examples in the literature

have applied MAPs in areas such as inhibitors, artificial proteins, affinity purifications, and intracellular transport.

The MAP, which is chemically defined and homogeneous, was first intended as an approach to overcoming the limitations of the conventional method for producing anti-peptide antibodies. In the conventional approach, the peptide antigen is conjugated to a known large protein, or synthetic polymer carrier, to form a peptide-carrier conjugate. Although this approach has been used successfully in eliciting animal antibodies, it has several inherent limitations. First, only a small portion of peptide antigen is represented in the whole conjugate. Second, there is chemical ambiguity in the antigen composition and structure. Third, irrelevant epitopes and antibodies may be produced, and finally, carrier toxicity and carrier-induced epitope suppression may occur. The MAP systems have been used successfully to produce both polyclonal and monoclonal antibodies that specifically recognize native proteins. They have also been used to produce sera that have a significantly higher titer of antibodies than sera with antibodies against the same peptides conjugated to keyhole limpet hemocyanin (KLH) as a carrier protein (Tam, 1988).

Cyclic peptides are a powerful approach in the design of hormones and bioactive peptides, since favorable conformational constraints associated with biological activity can be fixed and conformational mobility diminished. In addition, the stability against biodegradation is increased. Cyclic peptides are also beneficial as peptide antigens, since they can elicit higher-quality antibodies than their linear counterparts. Based on these demands, the cyclic multiple antigen peptide (cMAP) approach (Spetzler and Tam, 1996; Zhang and Tam, 1997), which has branched multiple closed-chain architectures, was developed. The cMAP system is a superior approach for protein mimetics because the multiple constrained peptides can mimic bioactive conformations. Whether to select this approach over MAP depends on the properties of the peptides, but usually if the peptides are too small to adopt a stable conformation on their own, incorporation of a cyclic structure may be necessary.

Two methods for preparing MAP systems are described in this unit. The direct approach for preparing MAP systems is presented in the first two protocols, including the procedure

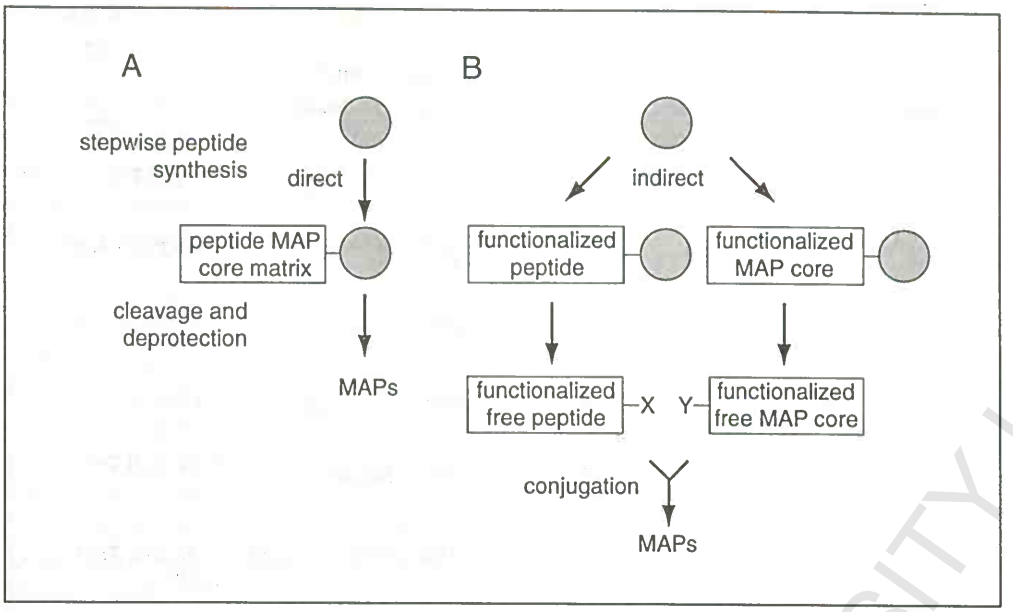

Figure 18.5.2 The direct and indirect approaches for preparing MAPs. Spheres represent the solid support; the MAP core matrix is Lys_2-Lys-Ala-OH or Lys_4-Lys_2-Ala-OH; X represents nucleophile; Y represents electrophile.

for *t*-butyloxycarbonyl (Boc) chemistry (see Basic Protocol 1) and the procedure for 9-fluorenylmethyloxycarbonyl (Fmoc) chemistry (see Alternate Protocol). An indirect approach for preparing MAP systems, in which peptide and core matrix are synthesized separately and conjugated by several ligation methods, is then described (see Basic Protocols 2 and 3). The cMAP approach is also executed using either the direct or indirect approach, but requires an additional cyclization step to constrain the peptides after synthesis. The synthesis of cMAP is described (see Basic Protocols 4, 5, and 6), and the preparation of cyclic peptides is illustrated (see Support Protocols 4, 5, and 6). Support Protocol 1 describes the ninhydrin assay to assess the completeness of the coupling reaction. In most cases, MAP systems can be used directly after simple dialysis or desalting. Some immunological studies, however, require purified MAPs. Support Protocols 2 and 3 describe MAP system purification by dialysis and high-performance gel-filtration chromatography.

STRATEGIC PLANNING

Realizing the distinction between the direct and indirect approach is essential (Fig. 18.5.2) when synthesizing MAP systems. In the direct approach, the MAP core is formed by attaching several layers of lysine to the resin, which contains either Gly or Ala, using solid-phase peptide synthesis (Merrifield, 1963; *UNIT 18.1*). The peptide is then assembled onto this MAP core matrix (Basic Protocol 1 and Alternate Protocol). After the synthesis, the entire MAP is deprotected and cleaved from the resin. In the indirect approach, the MAP core and peptide are prepared and purified separately (Basic Protocols 2 to 3). Then, they are linked together in the absence of any side-chain protecting groups, after purification, to form a completed MAP. For preparing MAPs by either the direct or indirect approach, both the peptide synthesis and the ligation chemistry are easy to perform. Other features of the direct and indirect approach are discussed in the Commentary (see Background Information). However, the considerations for choosing a direct or indirect approach involve requirements for purity, properties of the peptide antigens, and time factors.

Figure 18.5.3 Available methods for preparing cyclic peptides from unprotected linear peptides. Notes: (*a*) arrow indicates the direction of the amide bond; (*b*) types of cyclic peptides are designated as e-e, end-to-end; e-s, end-to-side chain; and s-s, side-chain-to-side-chain; (*c*) an electrophile/nucleophile pair is placed at the ends or side chain of the linear peptide (e.g., for formation of e-e cyclic peptide, the amino nucleophile is Cys and the carbonyl electrophile can be a thioester); (*d*) R = $(CH_2)_2$-$CONH_2$; (*e*) from periodate oxidation of a C-terminal glyceric ester; (*f*) from periodate oxidation of Ser and Thr attached to side chain of Lys.

For generating cMAPS, peptides on the core matrix need to be constrained as an additional step. A key tactic in the authors' strategy for preparing cMAP is the use of unprotected peptides as precursors. In the past few years, the authors' laboratory has developed a plethora of methods to form cyclic peptides from unprotected linear peptides in aqueous solution. Figure 18.5.3 lists those methods that are useful in preparing cMAPs. In planning of the cMAP synthesis, two questions need to be addressed: (1) how should the peptide antigen be constrained and (2) what are the suitable methods? The following are simple guidelines in the strategic planning for preparing cMAPs.

There are three general methods for constraining peptides in the cMAP system: end-to-end, end-to-side chain, and side chain-to-side chain (Figure 18.5.3). In one example (Basic Protocol 4) using the direct approach, cMAP is self-assembled via thiazolidine linkages after its unprotected precursor is synthesized by solid-phase synthesis. This procedure produces cyclic peptides that are linked in an end-to-side chain manner. A similar strategy can be applied for end-to-end or side chain-to-side chain methods by modifying the synthetic strategy accordingly. Peptides with a motif that favors a cyclic structure are highly recommended in this approach. Two other procedures (Basic Protocols 5 and 6) describe the use of an indirect approach for the synthesis of purified cMAP in two distinct steps. These protocols involve the synthesis of side chain-to-side chain and end-to-end cyclic peptides containing a free thiol, which are then linked to a MAP core matrix

A critical point in the preparation of both MAP and cMAP is the selection of the linear peptide sequences. Some of the available methods for identifying potential bioactive sequences include peptide library approaches (Tam et al., 1991; Houghten et al., 1991),

PDU IASRI CENTRAL UNIVERSITY LIBRARY

simultaneous synthesis of a high number of peptides (*UNIT 18.2*), and computer-assisted modeling (*UNIT 18.3*).

The procedures described in this unit involve use of an automated peptide synthesizer (e.g., Perkin-Elmer Applied Biosystems). For Boc syntheses, a special hydrogen fluoride cleavage apparatus (Peptide Institute or Peninsula Laboratories) and hood are required. Manual procedures can also be used (Stewart and Young, 1984). A detailed discussion of peptide synthesizers and reagents is presented in *UNIT 18.1*.

CAUTION: Some chemicals used in these procedures are harmful. *N-N'*-dicyclohexylcarbodiimide (DCC) can cause severe allergy in sensitive persons. Avoid any skin contact with DCC! Benzotriazolyl *N*-oxytrisdimethylaminophosphonium hexafluorophosphate (BOP) and 2-(1H-benzotriazol-1-yl)-1,1,3,3-tetramethyl uronium hexafluorophosphate (BBTU) can be used as alternatives to DCC. Trifluoroacetic acid (TFA) is a toxic, volatile organic acid and should only be used under a hood. Besides being toxic, hydrogen fluoride (HF) is also highly corrosive to glass instruments. Never use glass instruments or containers in HF cleavage. Thick polyvinyl gloves and a protective face mask should be worn. More details about these chemicals can be found in the literature (Stewart and Young, 1984).

DIRECT Boc SYNTHESIS OF MAP SYSTEMS

BASIC PROTOCOL 1

In the direct approach for preparing MAP systems, the MAP core is first formed by attaching several levels of lysine onto an amino acid coupled to a resin matrix. The peptide sequence is then assembled stepwise on this MAP core resin. After peptide assembly is complete, the MAP system is cleaved from the resin support (Tam, 1988). The procedure for preparing MAP systems by the direct approach using Boc chemistry is presented in Figure 18.5.4 and Table 18.5.1. Solid-phase peptide synthesis (Merrifield, 1963) using

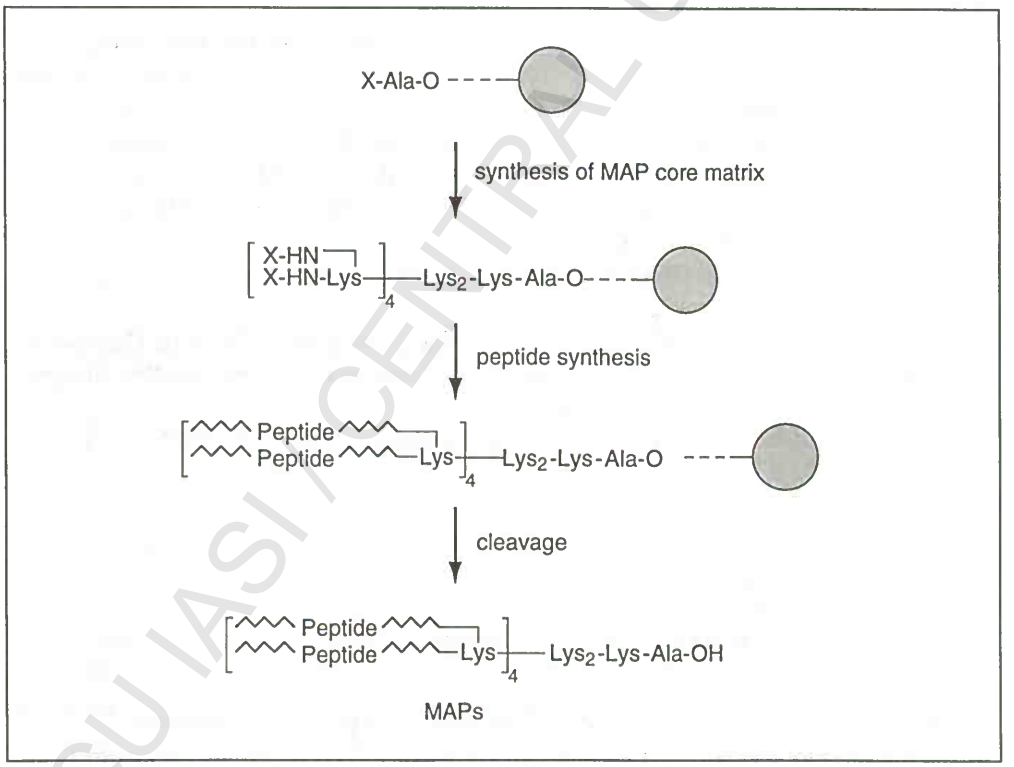

Figure 18.5.4 Direct approach of preparing MAPs with an octabranched core matrix. Sphere represents solid support; X represents Boc or Fmoc.

BSU IASI / CENTRAL UNIVERSITY LIBRARY

Table 18.5.1 Schedule for Boc Solid-Phase Peptide Synthesis

Reaction	Description	Volume (ml/g resin)	Repetitions and time
1	DCM wash	15	3 × 1 min
2	50% (v/v) TFA/DCM prewash	15	1 × 1 min
3	50% (v/v) TFA/DCM deprotection	15	1 × 20 min
4	DCM wash (5×)	15	5 × 1 min
5	5% (v/v) DIEA/DCM prewash	15	1 × 1 min
6	5% (v/v) DIEA/DCM neutralization	15	1 × 5 min
7	DCM wash (5×)	15	5 × 1
8[a]	Boc-AA (3 eq) in DCM	5	1 × 1 min[b]
9	DCC (3 eq) in DCM	1	1 × 30 min[b]
10	Addition of DMF	15	1 × 30 min
11	DMF wash (2 times)	15	2 × 1 min
12	DCM wash (2 times)	15	2 × 1 min
13[c]	Ninhydrin test	—	5 min

[a]In case of coupling of Boc-Asn-OH, and Boc-Gln-OH, the DCC/HOBt coupling method should be used to avoid dehydration of unprotected side chain amide groups. Alternatively use Boc-Asn(Trt)-OH and Boc-Gln(Trt)-OH to minimize degradation side reactions. Boc-Arg(Tos)-OH should also be coupled with the DCC/HOBt method.

[b]Do not drain until the completion of reaction 10.

[c]If ninhydrin test does not show completion of coupling reaction (>99.5%), repeat reactions 7 to 13.

Boc chemistry involves prewashing the resin, removing the Boc protecting group, neutralizing the resin, coupling the next Boc–amino acid residue, and then repeating this cycle until the complete peptide sequence is assembled. Finally, the peptide is cleaved from the resin support.

Materials

Synthesis reagents (Table 18.5.1; prepared as described in Stewart and Young, 1984):
- Dichloromethane (methylene chloride, DCM)
- 50% (v/v) trifluoroacetic acid (TFA) in DCM (TFA/DCM)
- 5% (v/v) diisopropylethylamine (DIEA) in DCM (DIEA/DCM)
- 1.0 M *N,N′*-dicyclohexylcarbodiimide (DCC) in DCM (DCC/DCM)
- *N,N′*-dimethylformamide (DMF)

0.1 mmol/g Boc-β-Ala-OCH_2-PAM-resin (Bachem California)

Boc-Lys(Boc) (Bachem California)

Boc-amino acids (Boc-AA), with protected side-chain groups (Bachem California, Peninsula Laboratories) appropriate for synthesis of the desired peptide antigen, dissolved in dichloromethane (DCM).

10% (v/v) thiophenol in DMF *or* 10% (v/v) mercaptoethanol (2-ME)/5% (v/v) DIEA in DMF

p-cresol

p-thiocresol

Dimethyl sulfide (DMS)

Liquid hydrogen fluoride (HF), –78°C

99:1 (v/v) cold diethyl ether/2-mercaptoethanol (2-ME)

10% (v/v) acetic acid in water

Automated peptide synthesizer (e.g., Perkin-Elmer Applied Biosystems #ABI430A)

Manual reaction vessel (Pierce)

Hydrogen fluoride cleavage apparatus (Peptide Institute or Peninsula Laboratories)

BOU IASI / CENTRAL UNIVERSITY LIBRARY

50-ml round-bottom flask
Coarse- and fine-porosity fritted glass funnels
50°C water bath

Prepare the core matrix

1. Place 0.5 g of 0.1 mmol/g Boc-β-Ala-OCH_2-PAM-resin in a reaction vessel in an automated peptide synthesizer. Begin the synthesis, using the synthesis reagents and directions outlined in Table 18.5.1, making the substitutions in reaction 8 of the table as described in step 2a, b, or c.

   Reactions 1 through 13 (Table 18.5.1) constitute one complete cycle; one cycle is required for each amino acid in the sequence. Some automated synthesizers may include the test to evaluate the coupling reaction in their cycle; if not, the ninhydrin test (reaction 13) will have to be performed manually (Support Protocol 1, Sarin et al., 1981).

   β-alanine is used as an internal standard for amino acid analysis which provides the molar ratios of other amino acids against β-alanine. Instead of β-alanine, other simple amino acids such as alanine can also be used.

2a. *To prepare a MAP core matrix with two lysine branches*: In reaction 8 of the first cycle, couple 0.15 mmol (52 mg) Boc-Lys(Boc) to the resin added in step 1. Proceed to step 3.

2b. *To prepare a MAP core matrix with four lysine branches*: Complete step 2a, then, in reaction 8 of the second cycle, couple 0.3 mmol (104 mg) Boc-Lys(Boc) to the resin from step 2a. Proceed to step 3.

   The substitution level doubles with each coupling of Boc-Lys(Boc).

2c. *To prepare a MAP core matrix with eight lysine branches*: Complete steps 2a and 2b, then, in reaction 8 of the third cycle, couple 0.6 mmol (208 mg) Boc-Lys(Boc) to the resin from step 2b. Proceed to step 3.

   Preformed MAP core matrix is also commercially available from Applied Biosystems, Bachem California, and Calbiochem-Novabiochem.

Synthesize the peptide on the MAP core matrix

3. Perform synthesis of the peptide on the MAP core matrix prepared in step 2a, b, or c by carrying out the reactions in Table 18.5.1 (one cycle of 13 reactions per amino acid), using, in reaction 8 of the table, 0.15 mmol of Boc-amino acids for a MAP core matrix with two branches, 0.3 mmol of Boc-amino acids for a MAP core matrix with four branches, or 0.6 mmol of Boc-amino acids for a MAP core matrix with eight branches, based on 0.05 mmol of starting Boc-β-Ala-OCH_2-PAM resin.

   Select the appropriate Boc-amino acids for the synthesis of the peptide antigen.

   For descriptive purposes, the peptide antigen IEDNEYTARQG (IG-11) is used in this protocol. For this peptide, the Boc-amino acids would be Boc-Gly, Boc-Gln, Boc-Arg (Tos), Boc-Ala, Boc-Thr(Bzl), Boc-Tyr(BrZ), Boc-Glu(OBzl), Boc-Asn, Boc-Asp (OBzl), and Boc-Ile for the synthesis of IG-11-MAP. The peptide chain would be assembled in sequence G, Q, R, A, T, Y, E, N, D, E, I. The most commonly used side-chain-protecting groups for Boc amino acids are: Ser and Thr, benzyl ether (Bzl); Asp and Glu, benzyl ester (OBzl); Asn, and Gln, unprotected or trityl (Trt) amide; Met, unprotected; Tyr, 2-bromobenzyloxycarbonyl (BrZ); Arg, toluenesulfonyl (Tos); Lys, 2-chlorobenzyloxycarbonyl (ClZ); His, N^{im}-2,4-dinitrophenyl (Dnp); Trp, N^{in}-formyl, Cys, p-methylbenzyl (MeBzl), or acetamidomethyl (Acm). Some special side-chain-protecting groups can also be found in the literature listed at the end of this unit (see Literature Cited).

4. After synthesis of the peptide is complete, transfer the resin to a manual reaction vessel and remove the Dnp from peptide residues with N^{im}-Dnp protecting groups using 10% thiophenol in DMF (three 8-hr treatments, 5 ml each), or 10% 2-ME/5% DIEA in DMF (two 30-min treatments, 5 ml each).

BUNDESZENTRAL UNIVERSITY LIBRARY

5. Remove N-terminal Boc groups by treating for 20 min with 10 ml of 50% TFA/DCM, neutralize the resin with 10 ml of 5% DIEA/DCM, and then wash the resin five times, each time with 10 ml DCM (procedure similar to "reactions 1 to 4" in Table 18.5.1). Place the reaction vessel in a desiccator, and dry the resin under a vacuum.

   Boc groups would be removed in HF cleavage. It is advisable, however, to remove these t-butyl protecting groups prior to HF cleavage to avoid generating long-lived, reactive t-butyl cations during HF cleavage.

Cleave the peptides

6. Place 300 to 500 mg of MAP resin in the reaction vessel of the hydrogen fluoride cleavage apparatus. Melt *p*-cresol and *p*-thiocresol by placing bottles in 50°C water bath. Add 0.75 ml of the *p*-cresol and 0.25 ml of the *p*-thiocresol to the reaction vessel. Once this mixture has cooled to room temperature and solidified, add a magnetic stir-bar and 6.5 ml DMS to the reaction vessel and mix by stirring for 2 min at low speed without splattering resin on the reaction vessel.

7. *For low HF cleavage:* Add liquid HF at –78°C to give a final volume of 10 ml 7.5/2.5/65/25 (v/v/v/v) *p*-cresol/*p*-thiocresol/DMS/HF. Equilibrate the mixture to 0°C by immersing the reaction vessel in an ice bath and stirring. Stir the mixture vigorously for 2 hr at 0°C, and remove HF and DMS under a vacuum. Proceed to step 8 for high HF cleavage, or work up reaction as in step 9.

   CAUTION: *HF cleavage must be performed in a well ventilated chemical fume hood. Thick polyvinyl chloride gloves and a protective face mask must be used.*

   The outside wall of the vessel should have a predetermined mark for 10 ml.

8. *For high HF cleavage:* Recharge the mixture with 14 ml liquid HF at –78°C to give a final total volume of 15 ml HF/*p*-cresol/*p*-thiocresol. Stir the reaction mixture 1 hr at 0°C. Remove HF under a vacuum using a water aspirator at 0°C.

   See precautions for working with HF (step 7 annotation)

9. *Work up reaction:* Wash the residue by adding 30 ml of cold 99:1 diethyl ether/2-ME to the reaction vessel to remove *p*-thiocresol and *p*-cresol. Filter the resin and the precipitated peptide with a fritted-glass funnel in a 50-ml round-bottom flask. Discard the ether wash (the peptide will be distributed partially in the reaction vessel and partially in the fritted-glass funnel). Dissolve the crude peptide on both the reaction vessel and the fritted-glass funnel with 100 ml of 10% acetic acid, collect the filtrates, and lyophilize the solution to dryness. Store at –70°C.

ALTERNATE PROTOCOL

DIRECT Fmoc SOLID-PHASE SYNTHESIS OF MAP SYSTEMS

Fmoc synthetic chemistry is another widely used method for solid-phase peptide synthesis. The procedure for preparing MAP systems (Defoort et al., 1992) by the direct approach using Fmoc chemistry is presented in Figure 18.5.4 and Table 18.5.2. The basic procedure in Fmoc solid-phase peptide synthesis involves prewashing the resin, removing Fmoc protecting groups, and coupling the next Fmoc-amino acid residue. This cycle is repeated until peptide elongation is completed, and the peptide has been cleaved from the resin support.

Materials

Fmoc-Ala-Wang-resin (*p*-alkoxybenzyl alcohol resin preloaded with Fmoc-alanine at 0.3 to 0.5 mmol alanine/g resin; Bachem California)

Fmoc synthesis reagents

N,N'-dimethylformamide (DMF)

20% (v/v) piperidine in DMF (Pip/DMF)

0.5% (w/v) 1-hydroxybenzotriazole (HOBt) in DMF (HOBt/DMF)

9	DMF wash	15	5 × 1 min
10[c]	Ninhydrin test	—	5 min

[a]Coupling procedure for all amino acids.

[b]Do not drain until the completion of reaction 7.

[c]If ninhydrin test does not show completion of coupling reaction (>99.5%), repeat reactions 5 to 7.

Fmoc-Lys(Fmoc) (Bachem California; Peninsula Laboratories)
Acetic anhydride
Fmoc-amino acids (Fmoc-AA) with protected side-chain groups (Bachem California; Peninsula Laboratories) appropriate for synthesis of the desired peptide antigen, dissolved in DMT
Cleavage solution (see recipe), prepare fresh and prechill to 0°C
Anhydrous methyl *t*-butyl ether, cold
Anhydrous diethyl ether
10% (v/v) acetic acid in water
Automated peptide synthesizer (e.g., Perkin-Elmer Applied Biosystems #ABI430A)
Manual reaction vessel (Pierce)
Coarse- and fine-porosity fritted glass funnels

Prepare the resin

1. Place 0.5 g of 0.3 to 0.5 mmol/g Fmoc-Ala-Wang-resin in a reaction vessel in an automated peptide synthesizer. Couple 0.055 mmol (0.32 mg) Fmoc-Lys(Fmoc) onto the resin by carrying out reactions 1 to 9 in Table 18.5.2, adding the Fmoc-Lys(Fmoc) in reaction 6 of the table. Omit the ninhydrin test step.

   Reactions 1 through 10 (Table 18.5.2) constitute one complete cycle; one cycle is required for each amino acid in the sequence. Some automated synthesizers may include the test to evaluate the coupling reaction in their cycle; if not, the ninhydrin test will have to be performed manually (Support Protocol 1, Sarin et al., 1981).

   The commercially available Fmoc-Ala-Wang-resin usually has a loading of 0.3 to 0.5 mmol Fmoc-Ala/g resin. This content, however, is too high for synthesis of AMP (see Background Information). To prepare a resin with 0.1 mmol lysine/g resin at the first level in MAP core, only 0.055 mmol of Fmoc-Lys (Fmoc) should be used. This incomplete coupling will result in the loading of ~0.1 mmol lysine/g resin.

2. Add 15 ml DCM and 0.75 ml acetic anhydride to the reaction vessel and incubate 1 hr to terminate unreacted amines. Wash the resin five times with 10 ml DMF (1 min each) as in Table 18.5.2, reaction 9.

B. C. U. „M. EMINESCU" IAŞI
CHIMIE

BCU IAŞI / CENTRAL UNIVERSITY LIBRARY

As a result of the previous incomplete coupling step, an excess of free amino groups will be on the resin. This step will acylate (cap) free amino groups prior to coupling the next level of lysine.

Prepare the core matrix

3a. *To prepare a MAP core matrix with four or eight branches*: In reaction 6, couple 0.3 mmol (177 mg) Fmoc-Lys(Fmoc) to the resin from step 2 by following the reaction steps in Table 18.5.2. Proceed to step 3b (for core matrix with eight branches) or step 4 (for core matrix with four branches).

3b. *To prepare a MAP core matrix with eight branches*: In reaction 6, couple 0.6 mmol (354 mg) Fmoc-Lys(Fmoc) to the resin from step 3a by following the reaction steps in Table 18.5.2, adding the Fmoc-Lys(Fmoc) at reaction 6 in the table. Proceed to step 4.

Preformed MAP core matrix can be purchased from Applied Biosystems or Calbiochem-Novabiochem.

Synthesize the peptide on the MAP core matrix

4. Perform synthesis of the peptide on the MAP core matrix prepared in step 3a or b by carrying out the reactions in Table 18.5.2 (one cycle of 10 reactions per amino acid to be added) using, in reaction 6 of the table, 0.6 mmol of Fmoc-amino acids for a MAP core matrix with four branches or 1.2 mmol of Fmoc amino acids for a MAP core with eight branches.

The most commonly recommended side-chain-protecting groups for Fmoc-amino acids are: Ser, Thr, and Tyr, t-butyl ether (tBu); Asp and Glu, t-butyl ester (OtBu); Asn, Gln, trityl (Trt) amide; Arg, 2,2,5,7,8-pentamethylchroman-6-sulfonyl (PMC) or 4-methoxy-2,3,6-trimethylhenzenesulfonyl (Mtr); Lys, tert-butyloxycarbonyl (Boc); His, N^{im}-trityl (TrT) Trp, and Met, unprotected; Cys, trityl (Trt) thioether or acetamidomethyl (Acm). All are commercially available.

5. After completing the synthesis, perform reactions 1 to 4 in Table 18.5.2, to remove the Fmoc group on the amino group of N-termini (last coupling) with 20% pip/DMF. Wash the resin with 10 ml DMF (three times, 1 min each) and 10 ml DCM (three times, 1 min each).

Cleave the peptides

6. Transfer peptide/resin mixture to a manual reaction vessel. Add prechilled cleavage solution to the peptide/resin at a ratio of 10 ml cleavage solution per 0.2 to 0.4 g peptide/resin. Stir mixture 1.5 to 2 hr at room temperature.

Other cleavage solutions can be used. Reagent K [82.5:5:5:2.5:5 (v/v/v/v/v) TFA/thioanisole/phenol/1,2-ethanedithiol (EDT)/H_2O] can be used for peptides that contain multiple Arg and Trp residues. For simple peptides, a cleavage solution of 5% H_2O/95% (v/v) TFA can be used.

7. Filter the peptide/resin mixture through a coarse-porosity fritted glass funnel, and wash the resin three times, each time with 5 ml TFA. Concentrate the filtrate to a small volume (~2 ml) under a vacuum.

8. Precipitate peptide with 30 to 50 ml cold anhydrous methyl *t*-butyl ether.

9. Filter the peptide precipitate through a fine-porosity fritted glass funnel, and wash the peptide three times, each time with 10 ml anhydrous diethyl ether. Dry the crude peptide (in the glass funnel) under a vacuum.

10. Dissolve the crude peptide in 10% acetic acid and lyophilize to dryness. Store at –70°C.

PGU IASRI / CENTRAL UNIVERSITY LIBRARY

INDIRECT Boc AND Fmoc SYNTHESIS OF MAP SYSTEMS USING THIOL CHEMISTRY

MAP systems have been successfully prepared by the direct approach, but they can also be synthesized by an indirect approach. In this method, the peptide antigen and MAP core matrix are prepared and purified separately and then linked together through functional groups on both elements to form a MAP system (Fig. 18.5.2 and Fig. 18.5.5; Lu et al., 1991). The indirect approach combines the advantages of solid-phase peptide synthesis with those of conjugation in a solution phase. An unprotected, purified peptide can be used in ligation. The orientation of peptides, particularly those derived from sequences at or near carboxyl termini, can be arranged as in native protein by linkage through the N-terminus to the core matrix. A variety of functional groups have been used for ligation to guarantee site-specific, chemically unambiguous MAP systems (also see Background Information). This protocol describes ligation through a sulfhydryl group of Cys in the peptide and a chloroacetyl group on the MAP core matrix. The same ligation chemistry is used to attach cyclic peptides to the MAP core matrix (see Basic Protocol 6).

Materials

Chloroacetic acid (Aldrich)
1.0 M *N,N'*-dicyclohexylcarbodiimide (DCC) in DCM (DCC/DCM)
Sulfhydryl reducing solution (see recipe)
Nitrogen source
1 M Tris·Cl
1 M NaOH
0.1 M NH_4HCO_3 or 10% acetic acid

Additional reagents and equipment for solid-phase peptide synthesis using Boc (see Basic Protocol 1) or Fmoc chemistry (see Alternate Protocol), purification

of peptides via RP-HPLC (*UNIT 11.6*), dialysis (see Support Protocol 2), and high performance gel-filtration chromatography (see Support Protocol 3)

Prepare peptide antigen by solid-phase peptide synthesis

1. Synthesize the peptide using either Boc or Fmoc chemistry as in Basic Protocol 1 or the Alternate Protocol.

   For the ligation of peptide to a chloroacetylated MAP core matrix, an additional Cys should be attached to either C-termini (for peptide antigens derived from internal or N-terminal regions) or N-termini (for peptide antigens derived from the C-terminal region) of the peptide.

2. Purify the peptide using the methods in *UNIT 11.6* or in Support Protocols 2 and 3 of this unit.

Prepare chloroacetylated MAP core matrix

3. Prepare a MAP core matrix with four or eight lysine branches (see Basic Protocol 1, step 2), or Alternate Protocol, step 3).

4. Remove the N^{α}-terminal protecting group (see Basic Protocol 1, step 5, or Alternate Protocol, step 5).

5. Couple chloroacetic acid (4 molar equivalents) to the free amino groups of core matrix using 4 molar equivalents of DCC/DCM as a common amino acid coupling.

   This is done as in reactions 4 to 12 of Table 18.5.1 for Boc chemistry or reactions 4 to 9 of Table 18.5.2 for Fmoc chemistry, except that chloroacetic acid is being used instead of a protected amino acid.

6. Cleave the MAP core matrix from resin (see Basic Protocol 1, steps 6 to 9, for Boc-amino acids—using high HF cleavage—or Alternate Protocol, steps 6 to 8, for Fmoc-amino acids—using 95% (v/v) TFA in water as the cleavage solution).

7. Purify MAP core matrix using the methods in *UNIT 11.6* or in Support Protocols 2 and 3 in this unit.

Conjugate peptide antigen with chloroacetylated MAP core matrix

8. Dissolve 28 μmol peptide (from step 2) in 5 ml sulfhydryl reducing solution. Keep this solution under nitrogen and adjust pH to 6.0 to 6.5 with 1 M Tris·Cl. Flush the solution with nitrogen for 30 min, then seal the solution (no air contact) for 2 hr.

   Before the peptide is conjugated to the chloroacetylated MAP core matrix, the disulfide bond of the terminal Cys should be reduced to a sulfhydryl group by treatment with tributylphosphine (Bu_3P). Dithiothreitol (DTT) cannot be used for this purpose because DTT may react with the chloroacetylated core matrix.

   Note that this reaction is performed off-resin and in solution phase. On-resin conjugation can be performed by modifying the sequence of these reactions and the use of an aqueous-compatible resin support, e.g., PEG-modified resin, which is available commercially.

9. Add 4 μmol of the tetrabranched chloroacetylated MAP core matrix (from step 7) to the peptide solution (from step 8). Adjust the pH to 8.5 to 9.0 with 1 M NaOH. Stir the mixture 45 min at room temperature.

10. Dialyze the MAP system conjugate sequentially against 2 liters of 0.1 M NH_4HCO_3 or 10% acetic acid and then deionized water at room temperature, 8 hr each change. Lyophilize to dryness and store at –70°C.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

This dialysis procedure is different from that described in Support Protocol 2 because the peptides have already been purified.

11. Remove any byproducts by purifying the MAP conjugate by high-performance gel-filtration chromatography (Support Protocol 3).

INDIRECT Boc AND Fmoc SYNTHESIS OF MAP SYSTEMS USING CARBONYL CHEMISTRY

BASIC PROTOCOL 3

Another method for preparing the MAP system by the indirect approach is to exploit the selectivity of other weak bases, particularly in the condensation reaction with aldehydes (Fig. 18.5.5; Shao and Tam, 1995). Two types of weak bases can be used. The first type consists of conjugated amines whose basicities are lowered by neighboring electron-withdrawing groups such as hydroxylamine and substituted hydrazines. These react with aldehyde to form oxime from hydroxylamine and hydrazones from hydrazines. The second type contains the 1,2-disubstituted patterns such as 1,2-aminoethanethiol derivatives of N-terminal cysteine and 1,2-aminoethanol derivatives of N-terminal threonine. Proline-like rings such as thiazolidine or oxazolidine are formed from the reaction between an aldehyde and cysteine or threonine, respectively. An aldehyde moiety on a peptide or MAP core matrix can be obtained by $NaIO_4$ oxidation of N-terminal Ser, Thr, or Cys under neutral conditions to give an α-oxoacyl group. The additional weak base available for conjugation is attached to the N-termini of the peptide so the orientation of the peptide is C to N. However, the weak base-aldehyde chemistry has also been used to ligate constrained peptides to a MAP core matrix in the preparation of cMAP (see Basic Protocol 5).

Materials

Boc-aminooxyacetic acid (see recipe) *or* Boc-succinic acid hydrazide (see recipe)
Benzotriazolyl N-oxytrisdimethylaminophosphonium hexafluorophosphate (BOP) (Richelieu Biotechnologies)
Diisopropylethylamine (DIEA; Aldrich)
0.01 M sodium phosphate buffer, pH 7 (*APPENDIX 2E*)
Sodium periodate (Aldrich)
Ethylene glycol (Aldrich)
0.4 M sodium acetate buffer; mix equal volumes 0.4 M sodium acetate and 0.4 M acetic acid
Dimethyl sulfoxide (DMSO; Aldrich)
Dimethyl formamide (DMF)
0.1 M NaOH or glacial acetic acid
Argon source
C8 RP-HPLC column (see *UNIT 11.6*)

Additional reagents and equipment for solid-phase peptide synthesis using Boc chemistry (Basic Protocol 1) or Fmoc chemistry (Alternate Protocol), and purification of peptides by semipreparative RP-HPLC (*UNIT 11.6*)

Prepare the peptide by solid-phase peptide synthesis

1. Synthesize the peptide using Boc or Fmoc chemistry as in Basic Protocol 1 or the Alternate Protocol.

2. Remove the N-terminal protecting group (see Basic Protocol 1, step 5, or Alternate Protocol, step 5).

3. Couple (on-resin) the Cys residue (for thiazolidine ligation; 4 molar equivalents) to the free amino group of the peptide using 4 molar equivalents of DCC/DCM as a

BOJANSKI CENTRAL UNIVERSITY LIBRARY

common amino acid coupling (see Table 18.5.1, steps 4 to 12, for Boc chemistry, or Table 18.5.2, steps 4 to 9, for Fmoc chemistry). Couple Boc-aminooxyacetic acid (for oxime ligation) or Boc-succinic acid hydrazide (for hydrazone ligation; 4 molar equivalents) to the amino terminus of the peptide using 4 molar equivalents of 1:1 (molar:molar) BOP/DIEA, dissolved in DMF, as coupling reagent in reaction 9 of Table 18.5.1 (in place of the DCC).

For thiazolidine ring formation, an additional Cys residue is attached to the N-terminus of the peptide. For coupling through an oxime or hydrazone bond, the weak base is also placed at the N-terminus of the peptide.

Prepare the glyoxyl-MAP core matrix

4. Prepare the tetravalent MAP core matrix (Lys_2-Lys-Ala) by the stepwise solid-phase synthesis method using either Boc chemistry (see Basic Protocol 1 and Table 18.5.1) or Fmoc chemistry (see Alternate Protocol and Table 18.5.2).

   Normal resin loading, ranging from 0.3 to 0.9 mmol/g, is recommended since only four coupling steps are required.

5. Remove the Boc group with 50% TFA/DCM (see Basic Protocol 1) or the Fmoc group with 20% pip/DMF (see Alternate Protocol).

6. Couple the fully protected Ser residue to the MAP core matrix using DCC and HOBt as described in step 3.

7. Cleave the Ser_4-MAP core matrix from the resin by the high HF procedure, HF/*p*-cresol (9:1, v/v), as described for Boc chemistry (see Basic Protocol 1, steps 6 to 9) or 95% (v/v) TFA in water as described for Fmoc chemistry (see Alternate Protocol, steps 6 to 8), and lyophilize the intermediate without purification.

8. Dissolve 5.86 µmol (5 mg) Ser_4-MAP core matrix (from step 7) in 2 ml 0.01 M sodium phosphate buffer, pH 7, and add 46.9 µmol (10 mg) sodium periodate in a 2-ml microcentrifuge tube.

9. Stir the mixture for 5 min at room temperature, then quench the reaction by adding 93.8 µmol ethylene glycol (5.3 µl).

10. Isolate the product by semipreparative RP-HPLC as described in *UNIT 11.6*.

Conjugate peptide with glyoxyl-MAP core matrix

11. Prepare a 5 mM peptide stock solution in water using the peptide from step 3 and a 5 mM glyoxy-MAP stock solution in water using the purified MAP from step 10.

12. Add 400 µl of 0.4 M sodium acetate buffer and 40 µl of the 5 mM glyoxy-MAP stock solution (0.2 µmol glyoxy-MAP) to 400 µl of the 5 mM peptide stock solution (2 µmol peptide). Then, add 800 µl DMSO in the case of oxime and hydrazone ligation and 800 µl DMF in the case of thiazolidine ligation.

13. Adjust pH of the solution to 5.7 (for oxime and hydrazone ligation) or 4.5 (for thiazolidine ligation) using 0.1 M NaOH or glacial acetic acid.

14. Stir the mixture under argon for 8 hr at room temperature, and monitor the completion of the ligation on a C8 RP-HPLC column (*UNIT 11.6*).

15. Purify the MAP conjugate by semipreparative HPLC (*UNIT 11.6*). Lyophilize to dryness and store at –70°C.

BSU IASI CENTRAL UNIVERSITY LIBRARY

NINHYDRIN TEST

SUPPORT PROTOCOL 1

The ninhydrin assay is used to check for completeness of the coupling reaction (Sarin et al., 1981). It is performed at the end of each synthesis cycle, usually as described here.

Materials

Ninhydrin test reagents: Solution A/B mixture and Solution C (see recipe)
60% (v/v) ethanol in H_2O
0.5 M tetraethylammonium chloride in dichloromethane (DCM)

10 × 75–mm test tubes
100°C heating block
Pasteur pipet containing glass wool plug

1. At the end of each synthesis cycle (see Table 18.5.1 and Table 18.5.2), remove ~10 mg wet resin from the reaction vessel. Dry the resin 1 hr under vacuum in a desiccator.
2. Weigh a 3- to 5-mg sample of dry resin into a 10 × 75–mm test tube. Add 100 µl of the solution A/B mixture and 25 µl solution C. To another tube add only the ninhydrin test reagents without resin. Mix.
3. Heat both tubes 10 min in a heating block at 100°C. Cool tubes in cold water.
4. Add 1 ml of 60% ethanol to the tubes. Mix thoroughly and filter through a Pasteur pipet containing a glass wool plug.
5. Rinse the resin twice with 0.20 ml of 0.5 M tetraethylammonium chloride in DCM. Combine the filtrates.
6. Dilute the combined filtrate to 2 ml with 60% ethanol.
7. Measure the A_{570} of the sample filtrate against the reagent blank.

For routine monitoring, an effective extinction coefficient of 1.5×10^4 may be used.

PURIFICATION OF MAP SYSTEM BY DIALYSIS

SUPPORT PROTOCOL 2

The chemistry of solid-phase peptide synthesis has been significantly improved since it was first introduced in 1963. Now synthesis of peptides of 100 or more residues with satisfactory yield and purity is possible. In general, crude synthetic MAP systems (after the cleavage step) are pure enough for many purposes (e.g., for production of antisera). When highly purified MAP systems are required (e.g., for vaccines for humans), the crude synthetic product must be purified to near homogeneity. MAP systems can be purified by dialysis, gel-filtration chromatography, RP-HPLC (*UNIT 11.6*), and high-performance gel-filtration chromatography (Support Protocol 3). This protocol details the special procedure required for the sequential dialysis of MAP systems.

Materials

Crude MAP system (see Basic Protocol 1, 2, or 3, or Alternate Protocol)
0.1 M NH_4HCO_3/$(NH_4)_2CO_3$ (pH 8.0) in 8 M and 2 M urea
1 M acetic acid
Dialysis tubing (e.g., Spectra/Por 6, MWCO 1000, Spectrum)

1. Dissolve crude MAP system in 100 ml of 0.1 M NH_4HCO_3/$(NH_4)_2CO_3$ (pH 8.0) in 8 M urea.
2. Load the peptide solution into dialysis tubing.

BOURNS / CENTRAL UNIVERSITY LIBRARY

3. Dialyze the peptide solution sequentially against 2 liters of each of the following solutions, for 8 hr each, at room temperature:

   0.1 M $NH_4HCO_3/(NH_4)_2CO_3$ (pH 8.0) in 8 M urea
   0.1 M $NH_4HCO_3/(NH_4)_2CO_3$ (pH 8.0) in 2 M urea
   H_2O
   1 M acetic acid.

4. Remove peptide solution from dialysis tubing. Lyophilize to dryness. Store at –70°C.

SUPPORT PROTOCOL 3

PURIFICATION OF MAP USING HIGH-PERFORMANCE GEL-FILTRATION CHROMATOGRAPHY

In this protocol, a crude MAP system is dissolved in potassium phosphate and purified over a specialized gel-filtration column by HPLC.

Materials

10 mg crude MAP system (Basic Protocol 1, 2, or 3, or Alternate Protocol)
0.1 M potassium phosphate, pH 7.0 (*APPENDIX 2E*)

Column for high-performance gel-filtration chromatography (prepacked Bio-Sil TSK 250, 300-mm length × 7.5-mm i.d.; mol. wt. range for separation: 10 to 300 kDa; Bio-Rad #125-0062)
Guard column (75-mm length × 7.5-mm i.d.; Bio-Rad #125-0061)

Additional reagents and equipment for HPLC (*UNIT 11.6*)

1. Dissolve 10 mg crude MAP system in 1 ml of 0.1 M potassium phosphate, pH 7.0.
2. Set up HPLC system with the Bio-Sil TSK column linked to the guard column. Set UV detector at 225 nm. Equilibrate the gel-filtration column with 0.1 M potassium phosphate, pH 7.0, at a flow rate of 0.5 ml/min.
3. Inject 200 µl of the crude MAP solution (from step 1). Elute peptide at a flow rate of 0.5 ml/min. Collect the purified MAP product.
4. Repeat injection (step 3) four times to purify all of the material. Pool the purified MAP product.
5. Lyophilize MAP fraction to dryness. Store MAP at –70°C.

BASIC PROTOCOL 4

DIRECT SYNTHESIS OF END-TO-SIDE CHAIN cMAP

This approach is suitable for preparing cMAP with multiple end-to-side chain cyclic peptides. It combines solid-phase (on-resin synthesis) with solution-phase synthesis (off-resin cyclization; Spetzler and Tam, 1996). First, stepwise solid phase synthesis is used to assemble the peptides linked to the MAP core matrix on resin. The cMAP precursor is then cleaved from the resin, and its protecting groups removed. The peptide antigens are cyclized in cMAP in aqueous solution. The chosen sequences were peptide antigens derived from the V3 loop of the surface protein gp120 of human immunodeficiency virus-1 (HIV-1), MN strain. Two peptides with the sequence GPGRAFYTTKNIIG and KRKRIHIGPGRAFYTTKNIIG were used. The essential motif GPGR was placed in the middle of the antigen sequence. The cMAP precursor contains a tripartite design (Fig. 18.5.6). The first two parts are constant regions. Part 1 at the C-terminus contains a short peptide which can be used for identification, delivery to give an MHC class I molecule or a T-helper epitope, followed by a tetralysyl core matrix. Part 2 contains a specific chemical cleavage site AspPro that gives a monomeric cyclic peptide to verify the yield of the intrachain cyclization. This part may not be necessary if verification is

PDU IASRI CENTRAL UNIVERSITY LIBRARY

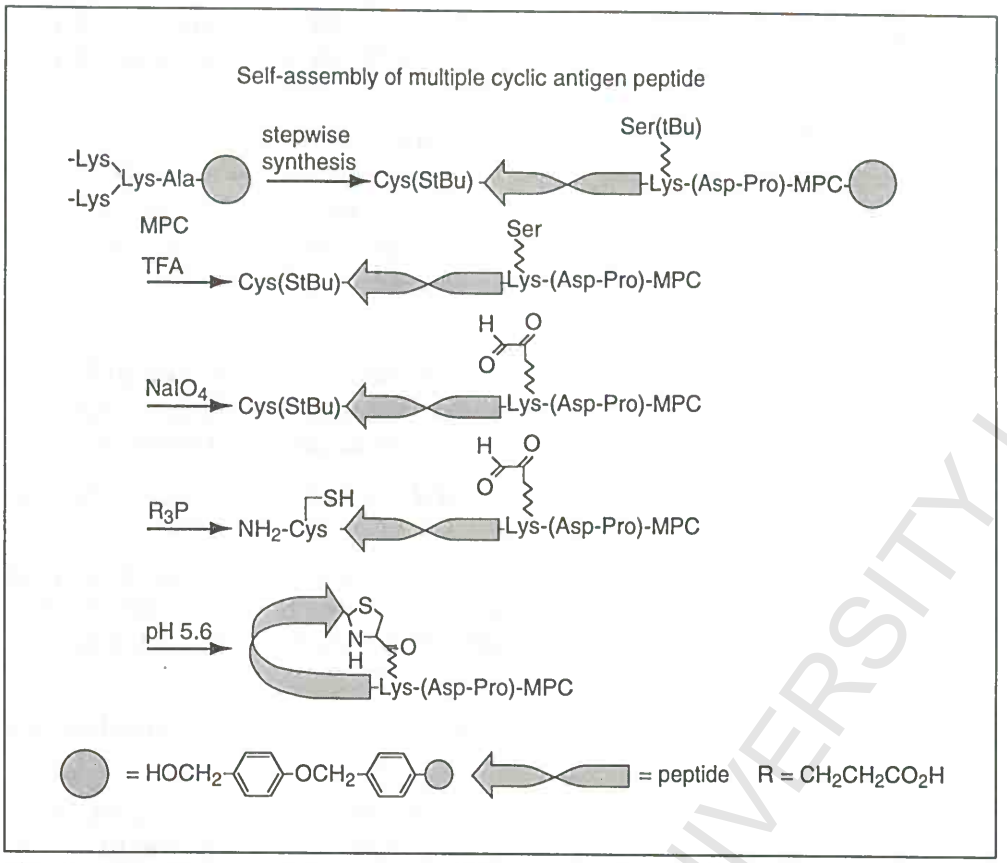

Figure 18.5.6 The scheme for preparing cMAP using the direct method.

not needed. The third part is the variable region and contains a peptide framed by a lysine at the COOH-terminus (ε-Lys) and a Cys at the amino terminus to give the end-to-side chain cyclic structure. The two mutually reactive functions are the α-Cys and a masked aldehyde attached to the side chain of the C-terminal lysine. Conversion to the aldehyde under mild aqueous conditions will permit an end-to-side chain cyclization via thiazolidine (Fig. 18.5.6). The protecting strategy for the two reactive moieties, Cys and aldehyde, is designed to be compatible with Fmoc chemistry (Alternate Protocol and Table 18.5.2) and the removal of these moieties under aqueous conditions. Sulfenyl tertbutyl is chosen for Cys as Cys(StBu) because it can be removed under aqueous conditions by trialkylphosphine and is stable to oxidation by periodate. The masked form of the aldehyde is the 1,2-aminoalcohol of a Ser residue anchored on the lysyl side chain. It can be converted to an aldehyde by periodate oxidation. The use of trialkylphosphine in the scheme has two advantages. First, it inhibits intermolecular disulfide formation as a side reaction, and second, it allows a one-pot reaction for unmasking the thiol protecting group and cyclization.

Materials

Fmoc-Lys[methyltrityl(Mtt)] (Calbiochem-Novabiochem)
Fmoc-Lys(Fmoc) (Bachem California)
Fmoc-Cys(StBu) (Calbiochem-Novabiochem)
1% (v/v) TFA/5% (v/v) triisopropylsilane (TIS; Aldrich) in DCM
Cleavage solution: 92.5/2.5/2.5/2.5 (v/v) trifluoroacetic acid (TFA)/triisopropyl silane (TIS) (Aldrich)/thioanisole (Aldrich)/H_2O, prepared fresh
0.01 M sodium phosphate buffer, pH 6.8 (*APPENDIX 2E*)

BOSTON UNIVERSITY MEDICAL CENTER LIBRARY

Sodium periodate (Aldrich)
Tris(2-carboxyethyl)phosphine hydrochloride (TCEP; Calbiochem-Novabiochem)
10 mM sodium phosphate, pH 6.8 (*APPENDIX 2E*)
10 mM sodium acetate buffer, pH 4.2 (*APPENDIX 2E*)
70% (v/v) formic acid in H_2O

Additional reagents and equipment for peptide synthesis (Alternate Protocol and Table 18.5.2), semipreparative HPLC (*UNIT 11.6*), and assay of free sulfhydryls with Ellman's reagent (*UNIT 18.3*)

Perform on-resin synthesis of the cMAP precursor

1. Synthesize the cMAP precursor starting from Fmoc-Ala-Wang resin (0.5 g, 0.1 mmol/g) manually or via an automated peptide synthesizer using the synthesis reagents and directions outlined in Table 18.5.2 and described in Alternate Protocol.

   The order of assembly of the precursor is: the MAP core matrix, the cleavage site Asp-Pro, Fmoc-Lys(Mtt), peptide sequence, and Fmoc-Cys(S-tBu). See Figure 18.5.6.

2. Remove (on-resin) the side-chain-protecting 4-methyltrityl (Mtt) group of Lys using 1% TFA/5% TIS in DCM using the procedure described in step 6 of the Alternate Protocol. Discard the TFA/TIS/DCM solution and neutralize the TFA-amine salt on-resin by performing reactions 4 to 7 of Table 18.5.1.

3. Couple Fmoc-Ser(tBu) to the lysyl side chain by DCC and HOBt procedure as a common amino acid coupling as in reactions 6 to 9 of Table 18.5.2.

4. Deprotect and cleave the precursor of cMAP from the resin by 92.5/2.5/2.5/2.5 (v/v) TFA/TIS/thioanisole/H_2O as outlined in the Alternate Protocol, steps 5 to 10. Lyophilize the peptide.

   Avoid thiol scavengers due to the presence of Cys(S-tBu).

Perform off-resin cyclization to form cMAP

5. Dissolve 0.44 µmol cMAP precursor (from step 4) in 2 ml 0.01 M sodium phosphate buffer, pH 6.8, and add 3.52 µmol (0.75 mg) sodium periodate in 27 µl water.

6. Stir the solution for 2 min, then purify the peptide by semipreparative HPLC as described in *UNIT 11.6*. Lyophilize the oxidized cMAP precursor.

7. Add 17.6 µmol (1.5 mg) TCEP in 47 µl of 10 mM sodium acetate buffer, pH 4.2, to the solution of oxidized cMAP in 1.5 ml of 10 mM sodium acetate buffer, pH 4.2.

8. Stir the mixture at 22°C for 48 hr, and monitor the progress of the cyclization by assay of free sulfhydryls with Ellman's reagent (*UNIT 18.3*) until all the thiols are consumed.

9. Purify cMAP by semipreparative HPLC as described in *UNIT 11.6*.

10. For determining the intrachain yield, add 0.5 ml 70% formic acid to 0.05 µmol of the lyophilized cMAP in a glass test tube. Incubate the solution either at 37°C for 48 hr or 60°C for 24 hr. Add 0.5 ml water and lyophilize the sample.

    This procedure will cleave the cyclic peptide at the AspPro site as a monomer.

11. Separate the monomeric sample by RP-HPLC (*UNIT 11.6*).

    The intrachain yield is calculated from the amino acid hydrolysis of the cMAP and the cyclic monomer.

PSU IAS/CENTRAL UNIVERSITY LIBRARY

INDIRECT Fmoc SYNTHESIS OF SIDE CHAIN-TO-SIDE CHAIN cMAP USING CARBONYL CHEMISTRY

In this approach, a side chain-to-side chain cyclized peptide is attached to the core matrix through a lysyl side chain (Pallin and Tam, 1996). The sequence used is a peptide antigen chosen from the neutralizing determinant of the V3 loop of gpl20. The target amino acid sequence is IGPGP. The precursors, which contain three Lys residues, are introduced as Fmoc-Lys(Mtt) and Boc-Lys(Fmoc), respectively, for attaching three functional groups (hydroxylamine, Ser, and Cys(StBu) through the side chains (Fig. 18.5.7). An *O*-alkyl-hydroxylamine group is attached to the side chain of the first Lys before the peptide sequence. The second Lys is introduced after the peptide sequence, and a Ser moiety is coupled to the side chain as a masked aldehyde, which is oxidized to an aldehyde by $NaIO_4$. A cyclic peptide is formed by using the intramolecular oxime formation from the reaction between *O*-alkylhydroxylamine and the aldehyde. A Cys(StBu) residue on the

1% (v/v) TFA/5% (v/v) triisopropylsilane (TIS; Aldrich) in DCM
20% piperidine in DMF (pip/DMF)
Boc-Ser(tBu; Bachem California)
Boc-(aminooxy)acetic acid (Bachem California)
Boc-Lys(Fmoc; Bachem California)
0.01 M sodium acetate buffer, pH 7 (*APPENDIX 2E*)
Sodium periodate ($NaIO_4$;Aldrich)
Ethylene glycol
0.1 M NaOH
Tris(2-carboxyethyl)phosphine hydrochloride (TCEP; Calbiochem-Novabiochem)
0.05 M sodium acetate buffer, pH 6 (*APPENDIX 2E*)
Tetravalent MAP core containing aldehyde groups (see Basic Protocol 3)
Acetic acid

Additional reagents and equipment for peptide synthesis (see Alternate Protocol and Table 18.5.2), semipreparative and preparative HPLC (*UNIT 11.6*), and mass spectrometry (Chapter 16),

Perform on-resin synthesis of the cyclic precursor

1. Synthesize the linear unprotected peptide by the stepwise solid phase strategy using the Fmoc chemistry protocol (see Alternate Protocol and Table 18.5.2) and couple the first Lys residue as Fmoc-Lys(Mtt).
2. Remove the Mtt protecting group using 1% TFA/5% TIS in DCM and couple Boc-Ser(tBu) to the side chain of Lys as described in step 2 of Basic Protocol 4.
3. Synthesize the peptide sequence using the Fmoc strategy as described in the Alternate Protocol.
4. Incorporate the second Lys residue as the Fmoc-Lys(Mtt) derivative.
5. Couple Boc-(aminooxy)acetic acid to its side chain.
6. Couple the third Lys as a Boc-Lys(Fmoc) derivative.
7. Remove the Fmoc group by 20% pip/DMF (see Alternate Protocol).
8. Couple Fmoc-Cys(StBu) to the side chain of lysine.
9. Cleave and purify the peptide precursor as described for Fmoc chemistry (Alternate Protocol).

Perform off-resin cyclization to form side chain-to-side chain cyclic peptides via an oxime linkage

10. Dissolve the peptide in 0.01 M sodium acetate buffer, pH 7, to give a final concentration of 0.8 M.
11. Oxidize the 1,2-amino alcohol moiety to the glyoxyl derivative by addition of a 2 M excess of $NaIO_4$ for 2 min at room temperature. Quench reaction with a >20-fold excess of ethylene glycol.
12. Purify the peptide by semipreparative HPLC (*UNIT 11.6*) to remove the formaldehyde byproduct.

BSU IASL / CENTRAL UNIVERSITY LIBRARY

13. Collect the product from semipreparative HPLC and adjust pH to 5.5 with 0.1 M NaOH, to effect the oxime cyclization.

14. Monitor the progress of the intramolecular cyclization by RP-HPLC (*UNIT 11.6*).

    The reaction is usually completed within 12 hr.

15. Characterize the cyclic peptide by mass spectrometry (Chapter 16).

Attach cyclic peptides to the MAP core matrix via a thiazoline linkage

16. Add 1.5 µmol (0.13 mg) TCEP to a solution of 0.3 µmol cyclic peptide in 0.5 ml of 0.05 M sodium acetate buffer, pH 6. Stir the mixture for 1 hr at room temperature.

17. Add 0.036 µmol tetravalent MAP core containing aldehyde groups (Basic Protocol 3) to the above mixture and adjust pH to 5 with acetic acid.

18. Stir the solution for 36 hr at 18°C, and purify the product by preparative HPLC as described in *UNIT 11.6*.

INDIRECT PREPARATION OF END-TO-END cMAP USING THIOL CHEMISTRY

BASIC PROTOCOL 6

In this protocol, the cyclic peptide is attached through its side chain to the core matrix (Zhang and Tam, 1997). The selected sequences were YGGFL and AVEIQFMHNLGK. First, the precursor of the unprotected cyclic peptide and the functionalized core matrix are synthesized by SPPS (Fig. 18.5.8). The cyclic peptide is generated by an intramolecular transthioesterification reaction in which the cyclization occurs under equilibration of ring chain tautomerization in aqueous solution. Sequentially, the end-to-end cyclic peptide is formed via an S- to N-acyl transfer reaction, and a Cys residue is generated. In this method, racemization is minimized, and the cyclization can occur in high concentration. The generated free thiol group of the Cys residue is then available for ligation. Preparation of the (chloroacetyl)lysyl MAP core matrix is described in Basic Protocol 2. In the second step, the thioether bond is formed between the cyclic peptide and the core matrix at slightly basic pH.

Materials

3-thiopropionic acid (Aldrich)
MBHA (*p*-methyl benzhydrylamine) or Gly-PAM resin (Calbiochem-Novabiochem)
1 mM dithiothreitol (DTT; Aldrich) in distilled water
20 mM Na_2HPO_4/10mM citric acid buffer, pH 7.5
Tris(2-carboxyethyl)phosphine, hydrochloride (TCEP; Calbiochem-Novabiochem)
0.2 M sodium phosphate buffer, pH 7.4 (*APPENDIX 2E*)/10 M ethylenediaminetetraacetic acid (EDTA; Aldrich)
Argon source
Tetravalent chloroacetyl(lysinyl) core matrix (see Basic Protocol 2)
Dimethylformamide (DMF)

Additional reagents and equipment for peptide synthesis (see Basic Protocol 1), preparative RP-HPLC (*UNIT 11.6*), and mass spectrometry (Chapter 16)

Perform on-resin synthesis of the cyclic precursor

1. Couple 3-thiopropionic acid to 0.5 g MBHA or Gly-PAM resin at 1.1 mmol/g by DCC/DCM in a reaction vessel (see Basic Protocol 1).

   Boc-Gly-PAM resin must be deprotected to give a free α-amine. The idea of this step is to form a reversible linker containing a thioester at the C-terminus after HF cleavage. For

BCU/AS/CENTRAL UNIVERSITY LIBRARY

an alternative method to prepare this resin, see recipe for thioester resin (HS-CH_2CH_2CO-MBHA-resin 1) for C-terminal thioester.

2. Add 1 mM DTT to the resin for 1 hr.

   Disulfide bonds may have been formed during the acylation reaction.

3. Synthesize the peptide sequence by stepwise solid phase synthesis (also see Fig. 18.5.7) either with an automated peptide synthesizer or manually using the synthesis reagents and directions outlined in Table 18.5.1 and Basic Protocol 1.

   Avoid the use of base-mediated coupling reagents such as benzotriazol-1-yl-oxy-tris(dimethylamino)phosphonium hexafluorophosphate (BOB), 2-(IH-benzotriazol-1-yl)-1, 1, 3,3-tetramethyluronium tetrafluorohorate (TBTU), and 2-(IH-benzotriazol-1-yl)-1,1, 3,3-tetramethyluronium hexafluorophosphate (HBTU), since the thioester is not stable to base.

4. Cleave the peptide thioester by the HF protocol as described in Basic Protocol 1. Purify the product by preparative RP-HPLC (*UNIT 11.6*). Lyophilize and characterize the product by mass spectrometry (Chapter 16).

P.U.U IASI CENTRAL UNIVERSITY LIBRARY

If the His residue is present in the sequence, use Boc-His(Tos) instead of Boc-His(DNP) which requires thiolysis to release the DNP protecting group.

Perform off-resin cyclization to form an end-to-end cyclic peptide containing an X-Cys ligation site

5. Dissolve 3.5 µmol linear peptide thioester (from step 4) in a solution of 2 ml of 20 mM Na_2HPO_4/10mM citric acid buffer, pH 7.5, containing 3.5 µmol (1.04 mg) TCEP.
6. Stir the solution for 6 hr, and monitor the progress of the intramolecular cyclization by RP-HPLC (*UNIT 11.6*).
7. Purify the cyclic peptide by preparative RP-HPLC as described in *UNIT 11.6*. Characterize and lyophilize the product.

Attach cyclic peptides to the MAP core via a thioether linkage

8. Dissolve 28 µmol cyclic peptide (from step 7) in 1.25 ml of 0.2 M sodium phosphate buffer containing 10 µM EDTA, pH 7.4.
9. Purge the solution with argon for 10 min.
10. Add 1.4 µmol (1.1 mg) tetravalent (chloroacetyl)lysinyl core matrix (prepared as described in Basic Protocol 2) predissolved in 0.75 ml DMF.
11. Stir the mixture for 24 hr at room temperature, then purify the cMAP by preparative RP-HPLC as described in *UNIT 11.6*.
12. Characterize cMAP by mass spectrometry (Chapter 16).

PREPARING END-TO-END CYCLIC PEPTIDES VIA AN X-CYS LIGATION SITE

SUPPORT PROTOCOL 4

In this protocol, an unprotected cyclic peptide containing an X-Cys ligation site is prepared (Liu and Tam, 1997). The sequence is a peptide antigen derived from the V3 loop of the gp120 of IIIB. The peptide precursor is synthesized on a thioester benzhydryl resin which, after HF cleavage, generates C^{α}-thiocarboxylic acid. A Cys residue activated as Cys(Npys) is incorporated at the amino-terminus. First, the end-to-end peptide is cyclized from formation of a mixed acyl disulfide which undergoes an intramolecular S,N-acyl transfer reaction. The generated hydrodisulfide (S-SH) can be reduced by thiolysis to give the native Cys-residue.

Materials

Thiobenzhydryl resin for C-terminal thioacid (see recipe)
Boc-Cys(Npys) (Bachem California)
25% acetonitrile/0.05% TFA in H_2O, pH 2
Sodium acetate, solid
Dithiothreitol (DTT; Aldrich)

Additional reagents and equipment for peptide synthesis (see Basic Protocol 1 and Table 18.5.1) and RP-HPLC (*UNIT 11.6*)

1. Perform on-resin synthesis of the cyclic precursor containing an X-Cys ligation site. Synthesize the precursor of the cyclic peptide on a thiobenzhydryl resin using the Boc-chemistry protocol as described in Basic Protocol 1 and outlined in Table 18.5.1. Cap the amino-terminal with Boc-Cys(Npys), and cleave and deprotect the peptide by HF.

The resulting precursor is a peptide with a Cys(Npys) residue at the N-terminal and a thiocarboxylic acid at the C-terminal. The other side chains are unprotected.

BOSTON UNIVERSITY LIBRARY

2. Initiate the cyclization after HF cleavage (see Basic Protocol 1) in 25% acetonitrile in H_2O containing 0.05% TFA, pH 2, giving a final concentration of 1.75 μM with respect to the peptide solution. Monitor the progress of the cyclization by RP-HPLC (*UNIT 11.6*).

   During the cyclization, a sulfur-sulfur exchange occurs first and a yellow color appears due to the release of Npys-H.

3. Adjust the solution to pH 6 by using solid sodium acetate to complete the cyclization reaction.

4. After 10 min, add 1 eq DTT to the solution to reduce the cysteinyl hydrodisulfide to cysteine, and monitor the reaction by RP-HPLC (*UNIT 11.6*).

5. Purify the cyclic peptide by preparative RP-HPLC as described in *UNIT 11.6*.

SUPPORT PROTOCOL 5

PREPARING END-TO-END CYCLIC PEPTIDES VIA AN X-THIAPROLINE LIGATION SITE

In this example, the unprotected peptide precursor is synthesized on an Fmoc-amino acid-*O*-CH_2-cyclic acetal resin (Botti et al., 1996). The peptide sequence is as follows: GRAFVTIGKIG derived from the V3 loop of gpl20, HIV-1. During the TFA cleavage, a glyceric ester is generated at the C-terminal. The diol of the glyceric ester is converted to glycoaldehyde by oxidation with $NaIO_4$. The precursor contains a Cys(StBu) residue at the N-terminus while all the other side chains are unprotected. Two steps are involved to form thiaproline. First, the thiazolidine ring is generated from the reaction between an aldehyde moiety and the 1,2-aminothiol of the N-terminal Cys. Then, an *O*- to *N*-acyl transfer reaction occurs through a tricyclic ring contraction to give a peptide bond. The thiazolidine ring formation is mediated after $NaIO_4$ oxidation and removal of the StBu protecting group, and the intramolecular *O*- to *N*-acyl transfer reaction occurs upon readjusting the pH to 5.9.

Materials

Fmoc-Gly-*O*-CH_2-cyclic-acetal resin (see recipe for acetal resin)
Cleavage solution: 91:3:3:3 (v/v) TFA/H_2O/thioanisole/anisole
$NaIO_4$
0.01 M sodium phosphate buffer, pH 5.5, 5.7 and 6 (*APPENDIX 2E*)
Tributyl phosphine (Bu_3P)
Isopropyl alcohol

Additional reagents and equipment for peptide synthesis (see Alternate Protocol 2 and Table 18.5.2) and RP-HPLC (*UNIT 11.6*)

1. Synthesize end-to-end cyclic peptides via a thiaproline ligation site. Assemble the peptide sequence on Fmoc-Gly-*O*-CH_2-cyclic-acetal resin by Fmoc chemistry using stepwise phase synthesis as described in the Alternate Protocol and Table 18.5.2. Cap the amino-terminal with Boc-Cys(StBu).

2. Cleave and deprotect the precursor as in the Alternate Protocol, steps 6 to 10, using a cleavage solution containing 91:3:3:3 TFA/H_2O/thioanisole/anisole and allowing the reaction procedure to proceed for 2.5 hr. Lyophilize the product (Alternate Protocol, step 10).

3. Add 30 μmol $NaIO_4$ in 0.3 ml 0.01 M sodium phosphate buffer, pH 5.7, to 7 μmol peptide glyceric ester also dissolved in 1 ml 0.01 M sodium phosphate buffer, pH 5.7. Stir the solution for 30 min, and purify the product by semipreparative RP-HPLC (*UNIT 11.6*).

BAU IASI CENTRAL UNIVERSITY LIBRARY

4. Dissolve 1.18 μmol peptide-glycoaldehyde (from step 3) in 0.2 ml 0.01 M sodium phosphate buffer, pH 5.5, and add 10.9 μmol tributyl phosphine (Bu_3P) in 30 μl isopropyl alcohol (1:10 v/v dilution of Bu_3P in isopropyl alcohol). Stir and monitor the progress of the cyclization by analytical RP-HPLC (*UNIT 11.6*). Purify and lyophilize the product.

   The starting product forms two products corresponding to the cis and trans isomers of the cyclic peptide.

5. Redissolve the purified peptide in 0.2 ml 0.01 M sodium phosphate buffer, pH 6, and monitor the amide formation by analytical RP-HPLC (the *O*- to *N*-acyl transfer can take up to several days). If the reaction is slow, warm up the solution to 40°C. Purify the product and analyze by HPLC.

PREPARING END-TO-SIDE CHAIN CYCLIC PEPTIDES VIA A THIAZOLIDINE OR OXIME LINKAGE

SUPPORT PROTOCOL 6

In these two examples (Pallin and Tam, 1995; Botti et al., 1996), the precursor contains a Lys residue which is introduced as an Fmoc-Lys(Mtt) for attaching Ser through its side chain. The sequences are peptide antigens ranging from 5 to 26 amino acids in length and are derived from the V3 loop of gp120, HIV-1. The 1,2-amino alcohol function of Ser acts as a masked aldehyde and can be converted to glyoxyaldehyde after treatment with $NaIO_4$. A Cys(StBu) moiety is incorporated at the N-terminus to generate a thiazolidine ring while Boc-(aminooxy)acetic acid is incorporated to form an oxime bond. All the other side chains are unprotected. The thiazolidine ring is formed by first oxidizing the amino-terminal Ser to an aldehyde moiety and then removing the StBu protection group by TCEP. In generating cyclic oxime peptides, cyclization occurs after oxidation to the aldehyde.

Materials

Fmoc-Lys(Mtt)
1% (v/v) TFA/5% (v/v) triisopropylsilane (TIS; Aldrich) in DCM
Boc-Ser(tBu)
Cleavage solution: 92.5/2.5/2.5/2.5 (v/v) TFA/TIS/thioanisol/H_2O
Sodium periodate
0.01 M sodium phosphate buffer, pH 6.8 (*APPENDIX 2E*)
0.01 M sodium acetate buffer, pH 4.2 (*APPENDIX 2E*)
Tris(2-carboxyethyl)phosphine, hydrochloride (TCEP; Calbiochem-Novabiochem)

Additional reagents and equipment for peptide synthesis (see Alternate Protocol and Table 18.5.2), RP-HPLC (*UNIT 11.6*), and mass spectrometry (Chapter 16)

1. Synthesize end-to-side chain cyclic peptides via a thiazolidine or oxime linkage. Assemble the peptide segment on a Wang resin by the Fmoc-chemistry protocol using stepwise peptide synthesis as described in the Alternate Protocol and outlined in Table 18.5.2.

   The order is as follows: X-protected peptide sequence-Lys[Boc-Ser(tBu)]βAla, where X = Boc-Cys(StBu) or Boc-NH-O-CH_2-CO-.

2. Couple the Lys residue as Fmoc-Lys(Mtt) and remove the Mtt protection group with 1% TFA,/5% TIS in DCM. Couple Boc-Ser(tBu) to the side chain of Lys (Alternate Protocol).

3. Cleave and deprotect the peptide (see Alternate Protocol, steps 6 to 10) using 92.5/2.5/2.5/2.5 TFA/TIS/thioanisol/H_2O and allowing the reaction to proceed for 1 hr. Lyophilize the crude product (Alternate Protocol, step 10).

BOULASI / CENTRAL UNIVERSITY LIBRARY

4. Add 1.55 μmol sodium periodate (0.33 mg) in 3.5 μl H_2O to 0.76 μmol peptide precursor dissolved in 1 ml 0.01 M sodium phosphate buffer, pH 6.8. Shake the solution for 2 min, and purify the product by semipreparative RP-HPLC (*UNIT 11.6*).

   For oxime formation, the intramolecular cyclization occurs after oxidation to the aldehyde. Purify and characterize the product.

5. Dissolve 0.94 μmol peptide in 1 ml 0.01 M sodium acetate buffer, pH 4.2, and add 9.3 μmol TCEP (2.3 mg) dissolved in 23 μl 0.01 M sodium acetate buffer, pH 4.2. Stir the solution, and monitor the cyclization by analytical RP-HPLC (*UNIT 11.6*). After purification by semipreparative RP-HPLC (*UNIT 11.6*), characterize the product by mass spectrometry (Chapter 16).

REAGENTS AND SOLUTIONS

Use Milli-Q-purified water or equivalent for the preparation of all buffers. For common stock solutions, see ***APPENDIX 2E****; for suppliers, see* ***SUPPLIERS APPENDIX****.*

Acetal resin

Add 0.2 g sodium bicarbonate to a suspension of chloromethylated polystyrene (1% divinylbenzene) copolymer (Merrifield resin, purchased, e.g., from Bachem California; 0.76 mmol/g, 0.5 g) in 3 ml DMSO. After stirring for 7 hr at 155°C, wash the resin with water, methanol, DMF, DCM, and diethyl ether and then dry under vacuum. To confirm the conversion of the chloromethyl resin to the aldehyde resin, use FT-IR analysis, which should show the typical carbonyl absorption at 1700.5 cm^{-1}, and microanalysis, which should show that the resin does not contain any chlorine. The benzaldehyde resin (0.59 mmol/g, 1.0 g) is suspended in 10 ml anhydrous dimethoxyethane with 1 g glycerol and 10 mg *p*-toluenesulfonic acid. After 24 hr at 90°C, wash the resin with a 1:1 (v/v) mixture of 3% sodium bicarbonate and 1,4-dioxane, followed by water, dioxane, DMF, methanol, DCM, and diethyl ether. Dry under vacuum. Use FT-IR analysis to monitor the disappearance of the carbonyl absorbance at 1700.5 cm^{-1}. To functionalize the acetal resin with a Fmoc-amino acid, activate the Fmoc-amino acid, e.g., Fmoc-Gly-OH (5.58 mmol, 1.66 g) using DCC (3 mmol, 0.62 g), dimethylaminopyridine (0.28 mmol, 35 mg), and HOBt (0.28 mmol, 44 mg) for 20 min in 10 ml DMF. Insoluble dicyclohexylurea is then removed, and the solution is added to a suspension of the glycerol-acetal resin (1.0 g) in 5 ml DMF. After 18 hr, wash the resin three times each with dioxane, DMF, methanol, DCM, diethyl ether and then dry under vacuum.

Microanalysis will indicate 0.71% of nitrogen, corresponding to a substitution of 0.5 mmol/g. UV absorbance of the cleaved Fmoc (wavelength 301 nm, I = 7840) will indicate a substitution of 0.5 mmol/g.

Boc-aminooxyacetic acid

Add 10 mmol carboxymethylamine hemihydrochloride (Aldrich) to a mixture of 20 ml dioxane, 10 ml water, and 10 ml 1 N NaOH on ice. Add 11 mmol di-*t*-butyl pyrocarbonate (Aldrich) to the above solution at 0°C and stir the solution overnight at room temperature. Adjust pH to 4 using diluted $KHSO_4$ and extract the product twice, each time for 30 min, with ethyl acetate. Dry the organic phase over $MgSO_4$. Evaporate the organic phase under vacuum, and recrystallize Boc-(aminooxy) acetic acid (Boc-$NHNH_2$) from ethyl acetate–hexane.

Boc-succinic acid hydrazide

On ice, dissolve 42 mmol Boc-$NHNH_2$ (Aldrich) in 20 ml dichloromethane (DCM) and add 40 mmol succinic anhydride. Then add 10 mmol diisopropylethylamine (DIEA) to the above solution at 0°C, and stir the solution for 6 hr at room

PSU IASL CENTRAL UNIVERSITY LIBRARY

temperature. Remove DCM under vacuum, and dissolve the residue in 60 ml ethyl acetate. Wash the solution twice with 15 ml 5% $KHSO_4$, twice with 10 ml saturated NaCl solution, and finally with 10 ml water. Dry the organic phase over $MgSO_4$, and evaporate the organic phase under vacuum. Wash the oily residue three times, each time with 20 ml ether-hexane and dry under vacuum.

Cleavage solution for Fmoc protecting group

90 parts trifluoroacetic acid (TFA)
6 parts thioanisole
3 parts 1,2-ethanedithiol (EDT)
1 part anisole
Prepare fresh and chill to 0°C

The above reagents are available from Aldrich

Ninhydrin test reagents

Solution A: Dissolve 40 g reagent grade phenol in 10 ml absolute ethanol.

Solution B: Dissolve 65 mg potassium cyanide in 100 ml water. Dilute 2 ml of this solution to 100 ml with freshly distilled pyridine. Mix solution A and solution B, and store indefinitely at 4°C.

Solution C: Dissolve 2.5 g ninhydrin in 50 ml absolute ethanol. Store solution C indefinitely, in the dark.

Pyridine from any commercial source may be used to prepare solution B and must be distilled before use. Reflux 500 ml pyridine with 2 g ninhydrin for 2 hr, then distill the pyridine and store several months at 4°C, in a brown bottle (away from light).

Sulfhydryl reducing solution

4.25 ml 6 M guanidine·HCl
0. 25 ml 5% (w/v) EDTA (50 mg EDTA/ml)
0.5 ml 2% (w/v) tributylphosphine (Bu_3P) in propanol
Prepare just before use

CAUTION: *Tributylphosphine (Bu_3P) is a highly toxic, volatile reducing agent and should only be handled in a chemical hood.*

Thiobenzhydryl resin 2 for C-terminal thioacid

Add thiolacetic acid (CH_3COSH, 30 mmol; Aldrich Chemical) and triethylamine (30 mmol; Aldrich Chemical) to a suspension of 4-methylbenzhydryl chloride resin (6 g, 3 mmol) in 60 ml DMF. React the mixture at 60°C for 12 to 18 hr until a negative silver chloride test (see below) of the resin indicates that no free chloride groups are present. Wash the resin three times each with DMF, DCM, CH_3OH, DCM, and DMF. Treat resulting resin with a mixture of cysteine methyl ester hydrochloride (9 mmol), triphenylphosphine (9 mmol), and DIEA (9 mmol) in DMF/DCM (3:1, v/v, 60 ml). After 2 hr, wash the resin thoroughly three times each with DMF, DCM, and CH3OH and dry under vacuum.

The yield from this procedure should be 6.3 g.

For the silver chloride test, remove ~20 mg of resin to a small glass test tube, add 0.5 ml of pyridine, and heat at 100°C in a heating block for 15 min in a well-ventilated hood. Cool and dilute with an equal volume of 0.1 N nitric acid. Add a few drops of 0.1 N silver nitrate solution. The presence of silver chloride precipitate indicates an incomplete reaction.

Thioester resin (HS-CH_2CH_2CO-MBHA-resin 1) for C-terminal thioester

Add 3-thiopropionic acid (1.2 ml, 13 mmol), HOBt (1.8 g, 13 mmol), and DIC (2 ml, 13 mmol) sequentially to a suspension of 4-methylbenzhydrylamine (MBHA) resin (6 g, 3.2 mmol) in 60 ml DMF. Shake the mixture at room temperature for 30 min until a ninhydrin test (see Support Protocol 1) of the resin indicates that no free

BOURNS COLLEGE OF GENERAL UNIVERSITY LIBRARY

amino groups are present. Wash the resin three times each with DMF, DCM, CH_3OH, DCM, and DMF. Treat resulting resin with a mixture of cysteine methyl ester hydrochloride (0.55 g, 3.2 mmol), triphenylphosphine (0.85 g, 3.2 mmol), and DIEA (0.68 ml, 3.9 mmol) in DMF/DCM (3:1, V/V, 60 ml). After 2 hr, wash the resin thoroughly three times each with DMF, DCM, and CH_3OH and dry under vacuum.

The yield from this procedure should be 6.3 g.

COMMENTARY

Background Information

The multiple antigen peptide (MAP) system was originally designed to replace the protein carrier and to overcome the limitations of conventional conjugation approaches (Tam, 1988, 1996; Posnett et al., 1988). The MAP system consists of three structural elements. A simple amino acid (e.g., alanine) is bound through a proper linkage to a solid-phase polymer to initiate the synthesis and serve as an internal standard. An inner core matrix is constructed from several levels of lysine to generate multiple reactive ends (two to eight ends) to which peptides can be linked. The surface layer is composed of either multiple copies of linear or cyclic synthetic peptides attached to the lysine inner-core matrix (Fig. 18.5.1). The MAP makes use of a limited sequential propagation of a trifunctional amino acid to form a low-molecular-weight core matrix. Lysine is suitable for this purpose because both N^{α}- and N^{ε}-amino groups are available as reactive ends. The sequential propagation of lysine generates $2n$ reactive ends, each of which can serve as an attachment site for peptides. The complete MAP has been shown to be large enough to stimulate immune responses.

The lysine core matrix is small; the bulk of the complex is formed by up to 16 peptides layered around the inner core matrix. As an example, a peptide dendrimer with an octabranched core matrix and eight copies of the peptide, each containing 14 amino acid residues, has a total molecular weight of 13 to 14 kDa. Only 7% of the mass is due to lysine residues of the core matrix; 93% of the mass is due to peptide sequences. The core matrix is oligomeric and contains noncationic peptidyl and isopeptidyl lysine amide on both N^{α}- and N^{ε}-termini of lysine. As a result, the MAP core matrix is totally bioinactive and functions only as a template to keep the multiple peptides together. It is the dendritic peptide chains on the core matrix that are likely to be mobile and contribute to the biological activity of the MAP system. Recently, Wrighton and co-workers (Wrighton et al., 1997) have used β-Ala-Lys as a pseudosymmetrical dendrimeric template and have attached two copies of the erythropoietin mimetic peptide (EMP) to the ε-amino group and the α-amino moiety, respectively. The two intramolecular disulfide bridges in EMP were formed by using an orthogonal protecting group scheme. As a result, the dimer has 100-times higher affinity for the erythropoietin receptor (EPOR) and 10-fold better antagonistic activity in vivo than the monomer.

The MAP system is chemically unambiguous, and the method of synthesis provides accurate knowledge of conformation and quantity of the peptide. The MAP system is also versatile. If half of the reactive lysine amino chains (i.e., ε-amino groups) are chemically blocked during synthesis, a peptide dendrimer containing two different peptide sequences can be constructed. For example, N^{α}- and N^{ε}-amino groups of lysine at the last level are orthogonally protected with *t*-butyloxycarbonyl (Boc) and 9-fluorenylmethyloxycarbonyl (Fmoc), respectively. The first peptide chain can be assembled on the N^{α}-termini of this special lysine core matrix using Boc chemistry. The Fmoc groups of N^{ε}-termini are not affected during the Boc synthesis. After synthesis of the first peptide is complete, the second peptide chain can be synthesized on the N^{ε}-termini using Fmoc chemistry. The entire MAP system with two different peptide sequences is then cleaved from resin by hydrogen fluoride (HF) cleavage. One such MAP system was used as the model for synthetic hepatitis B vaccines (Tam and Lu, 1989). The simplicity and flexibility of the design and synthesis of MAP also permit incorporation of a hydrophobic built-in adjuvant such as tripalmitoyl-*S*-glyceryl cysteine (P3C; Defoort et al., 1992).

Constrained peptides that mimic native protein conformations are highly desirable because of the advantages in improving their biological activity. To achieve such constrained peptides, linear peptide sequences need to be circularized and then attached to a lysyl MAP core matrix. This approach requires two types of synthetic manipulations: a cyclization strat-

PKU IAS/CPE LIBRARY

egy of a linear precursor and a chemoselective method to attach to the template. The conventional approach to achieving two synthetic components is usually cumbersome and requires a scheme of multi-tiered protecting groups. For example, conventional cyclization to form cyclic peptides requires a protection scheme for selected functional side chains. The reactions are carried out in organic solvent (off-resin) or solid phase (on-resin). After cyclization, the side-chain protecting groups are removed. This unit describes two simplified approaches (the direct approach and the indirect approach; also see Fig. 18.5.2) to form cMAPs through unprotected constrained peptides generated from their linear unprotected peptides under aqueous conditions. The authors' two approaches do not use protecting groups and produce cMAPs directly for a variety of purposes, including antigen scanning and generation of constrained peptide libraries. The direct and indirect methods for preparing cMAP are the same as for MAP, and include an extra cyclization step after the linear unprotected precursors are synthesized.

Synthetic peptides have been used extensively for production of site-specific antibodies for confirming the identity of proteins derived from recombinant DNA, for exploring biosynthetic pathways, and for defining precursor-product relationships (e.g., proenzyme and preproenzyme) and structural domains of proteins (Lerner, 1982). So far, the MAP approach has been used in the preparation of experimental vaccines (Amon and Horwitz, 1992) against hepatitis (Tam and Lu, 1989), malaria (Tam et al., 1990; Pessi et al., 1991), foot-and-mouth disease (Francis et al., 1991), and HIV (Defoort et al., 1992; Nardelli et al., 1992).

Various templates derived from peptide and organic compounds containing several peptide chains have been able to induce protein structural motifs like α-helix, β-sheet, β-turn, and loop conformations (Schneider and Kelly, 1995). Since the MAP system also has an increased ordered helical structure (Shao and Tam, 1995) and its synthesis is well established, MAP is suitable as a template to mimic proteins. Many important questions, such as how a certain structural motif can be induced and how the secondary structures interact with each other, can be addressed by using the authors' MAP system. Artificial enzymes can also be designed and generated because certain tertiary structures associated with a specific enzymatic activity can be mimicked on the surface of the MAP core matrix.

Critical Parameters

Chemistry of synthesis

The MAP system can be effectively synthesized by both Boc and Fmoc chemistry (Tam and Spetzler, 1997). The selection of the synthetic method depends on several factors, including peptide sequence, instrumentation requirements, cost, and chemical wastes. The most important factor is probably peptide sequence. For sequences very rich in amino acids that are susceptible to strong acid modifications [e.g., alkylation (Cys, Met, Trp, and Tyr), acylation (Glu), and dehydration (Asp-Gly, Asp-Ser)], Fmoc chemistry may provide better results than Boc chemistry. However, use of the low-high hydrogen fluoride cleavage technique has greatly reduced these types of side reactions. Sequences rich in Arg, Trp, Tyr, and Met, as well as peptides with proline as one of the first two residues from the C-terminus, may do poorly in Fmoc chemistry. Occasionally, a peptide cannot be successfully prepared by either of these two methods. A failed synthesis may be caused by sequence-dependent side reactions.

The second factor that affects the choice of synthetic method is the instrumentation requirement. In general, Fmoc chemistry is easier in operation and requires less equipment. Boc chemistry normally needs special equipment for the final hydrogen fluoride cleavage of peptide from resin. If cost is a consideration, Boc chemistry is preferable because Boc-amino acid derivatives are less expensive than Fmoc-amino acid derivatives. The nature and quantity of chemical wastes produced during synthesis should also be considered. The solvent, coupling reagent, and cleavage reagent wastes generated in Boc chemistry are acidic (due to TFA) and contain halogens (TFA, DCM). The waste generated by Fmoc chemistry is basic (due to piperidine) and is not halogen-containing; the DCM used in reaction 8 of the procedure (Table 18.5.2) is negligible in this regard. For the synthesis of cMAPs, the preparation of their linear precursors are often limited to either Boc or Fmoc chemistry depending on the cyclization method used (see discussion of Method of Synthesis, below). However, the same precautions have to be taken as for the synthesis of MAP.

Method of synthesis

Both direct and indirect approaches for preparing MAPs are presented in this unit. In the direct approach, the linear peptide sequence

BOURKE UNIVERSITY LIBRARY

and MAP core matrix are synthesized in a single operation, directly on the resin matrix, by stepwise solid-phase peptide synthesis (Basic Protocol 1 and the Alternate Protocol). The core matrix (two or three levels of lysine) is formed first by coupling lysine to a small amino acid attached to a resin support. The peptide sequence is then synthesized stepwise on this branched-lysine scaffolding. After peptide synthesis, the MAP is cleaved from the resin support. In the indirect approach, the MAP core matrix and peptide are synthesized separately, purified, and then combined to form the complete MAP by one of a number of different ligation methods illustrated in Figure 18.5.5 (Basic Protocols 2 to 3). One advantage of the indirect approach is that the components—MAP core matrix and peptide—are purified before conjugation. Any impurity generated during solid-phase peptide synthesis can be removed; this may be difficult in the direct approach because of the unique structural characteristic of MAP.

Preparation of cMAP using the direct approach can be complicated by competing intramolecular versus intermolecular cyclization. The competing reactions can be minimized for single-chain peptides under dilute conditions, but this is not possible for cMAPs because of simultaneous multiple peptide copies on the branched structure. Furthermore, extensive intermolecular cyclization among the precursors can also give polymers. The authors' solution for avoiding side products and for simultaneously obtaining a self-assembly process to give multiple cyclic peptide is based on ring-chain tautomerization. Ring-chain tautomerization is an entropy process and is conformation-driven as well as concentration-independent, to favor intra- over intermolecular reactions. The initial bond formation is reversible in ring-chain tautomerism. Thermodynamically stable products are formed under equilibrating conditions suitable for self-assembly of the multiple peptide chains on the dendrimer to form end-to-side chain cyclic peptides. In the synthetic scheme of cMAP, the ring-chain tautomerization for intramolecular cyclization is a thiazolidine ring generated from an N-terminal Cys and an aldehyde attached to the side chain of Lys (Fig. 18.5.6). Peptides with a motif that favor a cyclic structure are highly recommended in this approach.

The authors' schemes for preparing cyclic peptides by the indirect approach result in ligation sites of peptide bonds like X-Cys and X-SPro and surrogate peptide bonds such as thiazolidine and oxime that both are metabolically stable (Fig. 18.5.3). These schemes also produce peptides which are cyclized through end-to-end, end-to-side chain, or side chain to side chain (Pallin and Tam, 1995, 1996; Botti et al., 1996; Zhang and Tam, 1997), depending on the strategic placement of the two intended sites that must react with each other. Although peptide and nonpeptide bonds are described, the chemistries governing their syntheses are rather similar. To generate unprotected cyclic peptides with peptide bonds such as X-Cys and X-SPro from linear unprotected precursors, the reaction must be regioselective (Liu and Tam, 1994; Tam, 1995). A common strategy for obtaining regioselectivity is entropic activation achieved by capturing the N^{α}- and C^{α}-termini at close proximity as a covalent bond allowing an intramolecular acyl shift and forming a peptide bond. In cyclization reactions, the capturing reaction between an N^{α}-amine and a weakly activated C^{α}-acyl moiety has to be specific in the presence of many other side-chain functional groups, including N^{ε}-amine. Two methods are available to form a Cys bond in the ligation site. In one method, cyclization is achieved via an intramolecular transthioesterification of the linear precursor containing an N-terminal Cys and a C-terminal thioester. The thioester intermediate subsequently undergoes a proximity-driven S- to N-acyl transfer to give the desired amide bond, and introduces a thiol moiety (Basic Protocol 5). In the other method, the cyclization occurs via an acyl disulfide–mediated intramolecular acylation. The linear precursor consists of an N-terminal Cys protected and activated as Cys(Npys) and a C-terminal thiocarboxylic acid. The mixed disulfide undergoes an S to N-acyl transfer through a six-member ring and a native Cys residue is obtained after thiolytic reduction (Support Protocol 4). Cyclic peptides with a thiol moiety are useful as building blocks in the indirect approach for preparing cMAPs (see discussion of Method of Ligation, below). Also, cyclic peptides containing an SPro residue to mimic Pro can be generated (Support Protocol 2). The cyclization is mediated by an amine-aldehyde condensation. The linear precursor contains an N-terminal Cys and a C-terminal glycoaldehyde generated from $NaIO_4$ oxidation of the corresponding glyceric ester. The Cys residue is protected as Cys(StBu) because of its sensitivity to $NaIO_4$ oxidation. First, a thiazolidine ring is formed when the StBu protecting group is removed by phosphine. Then a proximity-driven *O* to *N*-acyl transfer reaction occurs through a tricyclic

IUPUI IAS-CENTRAL UNIVERSITY LIBRARY

ring contraction to afford the peptide bond. Cyclic peptides through side-chain-to-end and end-to-end can be achieved.

In the preparation of cyclic peptides with peptide bond surrogates from totally unprotected linear precursors, chemoselective ligation based on carbonyl chemistry is used. Carbonyl chemistry exploits the selectivity of weak bases in the condensation with an aldehyde under acidic conditions where the basic side-chain nucleophiles are protected by protonation. For the purposes here, weak bases such as thiols, hydrazides, and amino-oxy groups are available, since they are easy to incorporate into the peptide during solid-phase synthesis. An aldehyde is obtained by $NaIO_4$ oxidation of N-terminal Ser, Thr, or Cys under neutral conditions to give an α-oxoacyl group. A thiazolidine ring is formed from the reaction between the aldehyde and the 1,2-aminoethanethiol of N-terminal Cys. Under the same conditions, an amino group will form a reversible Schiff base with the aldehyde. The Cys residue, which is incorporated as Cys(StBu), can play a dual function in the synthetic scheme. First, it can be used for cyclization where the cyclization is mediated after deprotection of the thiol of Cys, as already mentioned above. Second, it can be applied for ligating unprotected cyclic peptides to a core matrix when the Cys residue is deprotected after the cyclic peptide is formed. Another weak base is aminooxy, which affords oxime at low pH. In the authors' scheme, the aldehyde group is attached to the side chain of Lys while the nucleophilic aminooxyl or cysteinyl moiety is incorporated to either the amino terminal of the peptide or through the side chain of Lys to afford end-to-side chain or side chain-to-side chain cyclic peptides.

Method of ligation

The advantage of the indirect approach is that conjugation between the unprotected peptide and MAP core is chemically unambiguous. The functional groups on the peptide chain and core matrix can be designed to avoid reacting with other functional groups on the peptide. A variety of conjugation methods and cross-linking reagents may be used for conjugation to avoid modification of the peptide. The methods described in this unit are some of many variations (Fig. 18.5.5). A pair of mutually reactive functional groups such as a nucleophile and an electrophile are introduced on the monomeric peptide and MAP core matrix, respectively. The two functional groups only react specifically with each other. The methods that use thiol and carbonyl chemistries are suitable for the preparation of both MAP and cMAP with nonpeptide bonds.

A thiol group can be selectively reacted in the presence of amine and other side-chain groups because it is a stronger nucleophile, especially in neutral or acidic conditions where the amine group is protonated. Haloacetyl (Fig. 18.5.5) is a functional group used for selectively reacting with a thiol group under neutral to slightly basic pH conditions. However, under these conditions, the thiol tends to be oxidized to disulfide. Both unprotected linear (Basic Protocol 2) and cyclic (Basic Protocol 6) peptides contain a free thiol that has been ligated to chloroacetyl groups incorporated on the lysine core matrix. The indirect approach using thiol chemistry also allows the peptides to be attached to the MAP core matrix through either the amino or the carboxyl terminus, increasing the flexibility of the design. However, other functional groups such as maleimide or aromatic thiols like 2-thiopyridyl, nitropyridyl sulfenyl, or 4-dithiopyridyl, which also react specifically with a thiol, can be applied to ligate unprotected peptides to the MAP core matrix.

Carbonyl chemistry that exploits the selectivity of weak bases in condensation with an aldehyde has already been mentioned (see discussion of Method of Synthesis, above) and is shown in Figure 18.5.5. Thiazolidine ring formation has been used to ligate both linear (Basic Protocol 3) and constrained peptides (Basic Protocol 5) to a MAP core matrix containing α-oxoacyl groups. Other types of weak bases are hydroxylamine and hydrazine, which afford oxime and hydrazone bonds with an aldehyde moiety. Oxime and hydrazone bonds in the ligation site have been suitable for linear unprotected peptides (Basic Protocol 3). Both types of weak bases are added to the N-terminus, so the peptide sequence will be oriented with the amino terminal residues proximal to the core matrix and the carboxyl terminal residues distal to core matrix.

The conjugation reactions listed in Figure 18.5.5 have some limitations. The haloacetyl derivative may react with amine or other nucleophilic groups in peptides in basic medium. This type of reaction will lead to chemical ambiguity of the conjugate. To prevent this reaction, the pH of the conjugating solution should not be above 9.0. Aldehyde groups reacting with N-terminal cysteine rapidly form a stable thiazolidine derivative at pH 4 to 6. The resulting thiazolidine is quite stable under normal manipulating conditions, but the aldehyde

BOSTON CENTRAL UNIVERSITY LIBRARY

itself is unstable. However, this can be circumvented by inert gas protection. Hydroxylamine and hydrazine react with aldehydes, forming an oxime and a hydrazone linkage, respectively, at pH ~5. Both linkages are stable at physiological pH (6 to 8), but the hydrazone derivative will be hydrolyzed at a lower or higher pH. The rate of hydrolysis is pH dependent. Stability of the linkage can be increased by reducing the hydrazone bond to hydrazine with sodium cyanoborohydride ($NaBH_3CN$).

Troubleshooting

After the peptide sequence is selected, MAP or cMAP with this special sequence can be synthesized by solid-phase synthesis. As with solid-phase peptide synthesis, the reactions of each cycle (including deblocking and coupling reactions) must be very efficient and should be driven to completion in a short time. The following calculations demonstrate the importance of high yield from each cycle. If the mean yield of each cycle of synthesis is 95%, the final yield for a peptide with 20 amino acid residues would be only 35.8%. However, if the yield of each cycle is 98%, 99%, 99.5%, or 99.9%, the total yields for the synthesis of a peptide with 20 residues would be 66.8%, 81.8%, 90.5%, or 98.0%, respectively. Furthermore, the byproducts produced in peptide synthesis usually closely resemble the desired peptide product in sequence and structure and are very difficult to remove by normal separation methods. Because our MAP system is a dendrimer, the degree of heterogeneity of peptide products will be much higher than that of solid-phase peptide synthesis. For example, in the synthesis of a MAP system with four branches, a 99% yield from each cycle results in 96% of MAP with the correct structure. If the mean yield of each cycle of synthesis is 99%, the synthesis of a four-branched MAP system with a peptide antigen of 20 amino acid residues will result in final yield of 44.2% with the correct sequence, instead of 81.8% obtained in usual solid-phase peptide synthesis.

The major side reactions during solid-phase peptide synthesis are: deletion, where one or more amino acid residues are skipped during synthesis; termination, where chain elongation stops at a point because of acylation or other side reaction; and racemization, where the amino acid is racemized during peptide elongation. All these side reactions result in heterogeneity of peptide product, and decrease the total yield of synthesis. To overcome these side reactions, excess amounts of reagents should be used in the synthesis to force reactions to completion and to shorten the reaction time. Double coupling or even coupling at elevated temperatures (50° to 60°C) should be used if a single coupling fails to complete the reaction.

Efficiency of synthesis should be closely monitored by the ninhydrin test (Support Protocol 1) or quantitative ninhydrin test (Sarin et al., 1981). The unusual properties of MAP systems (e.g., their multibranched structure and tendency to aggregate) should be considered to achieve a high-quality product. The synthesis should be started with a lower level of amino acid loading on the resin than is customary with usual solid-phase peptide synthesis, because peptide content will increase geometrically with each additional layer of lysine. Peptide synthesis will be difficult if the conventional loading of 0.3 to 0.8 mmol amino acid/g resin is used. In the Alternate Protocol for Fmoc chemistry, because resin with 0.1 mmol/g loading is not commercially available, synthesis starts with a resin of 0.3 to 0.5 mmol alanine/g resin, but only some of the amino groups are used for preparation of the dendrimer. Dimethyl formamide (DMF) is a more suitable solvent than dichloromethane (DCM) for avoiding potential aggregation of peptides. The peptide resin should not be dried at any stage of synthesis because resolvation of dried resin that contains MAP scaffolding is difficult.

During HF cleavage in Boc synthesis, several precautions should be taken to obtain satisfactory results. The HF line must be kept clean. The line should be checked before each cleavage. Very often, heterogeneous and complex peptide products are caused by a dirty, contaminated HF line. The HF line should also be checked for leaks before each cleavage. A leaky HF line can result in the loss of HF and dimethyl sulfide (DMS) during the cleavage reaction; this can lead to unsatisfactory results. A leaky HF line may also allow water and carbon dioxide into the reaction vessel, diluting the HF cleavage mixture. The cleavage mixture should be mixed completely during the reaction. Sometimes the magnetic stir-bar is frozen by the *p*-cresol or *p*-thiocresol mixture during the introduction of the reagent. This can be avoided by adding the reagents in the following order: (1) peptide resin, (2) *p*-cresol and *p*-thiocresol in melted form, then, after cooling and when the mixture has solidified, (3) the magnetic stirbar, and (4) DMS.

In Fmoc synthesis, trifluoroacetic acid (TFA) cleavage should be prolonged if the peptide contains Arg(Pmc). Thioanisole can

PSU IAS HERITAGE UNIVERSITY LIBRARY

accelerate the cleavage of the Pmc group. The deprotection of trityl (Trt) from cysteine residues is reversible, and scavengers such as thiophenol and 1,2-ethanedithiol (EDT) should be added to the cleavage mixture to prevent Trt reattachment to Cys. EDT also minimizes the alkylation reaction of Trp. The optimal volume of cleavage solution should be determined experimentally. In general, larger volumes of cleavage solution will, to some extent, suppress side reactions because most of the side reactions in the cleavage stage are bimolecular reactions. However, the more cleavage solution used, the larger the volume of TFA that must be removed, and the larger the amount of scavenger that will remain, making purification and analysis of the peptide more difficult. TFA can be reduced to a smaller volume under a vacuum by means of rotary evaporation, but the mixture should never be dried. A small-scale cleavage, using 20 to 30 mg of peptide resin, should be performed to determine optimal cleavage reaction conditions such as the combination and the ratio of scavengers, reaction time, and the volume of cleavage mixture. HPLC can be used to evaluate the results. Reaction conditions should be modified if the crude cleavage product is not as homogeneous as expected. The desired degree of purity should be ~60% or a major peak in the HPLC.

MAP systems prepared by the direct approach have been found to have an unusual tendency to aggregate after cleavage from the resin. The entire MAP should be dialyzed under basic, denaturing conditions using 8 M urea to remove unwanted additives from the cleavage reaction. Treatment with base under these conditions will also convert the possible strong acid–catalyzed *O*-acyl rearrangement product of serinyl and threonyl peptides back to *N*-acyl peptides. After dialysis, MAP systems can be further purified by either RP-HPLC or high-performance gel-filtration chromatography.

In the additional cyclization step for preparing cyclic unprotected peptide building blocks and the entire cMAP by the direct approach, some of the protocols involve oxidation with $NaIO_4$. The order of the synthetic scheme to generate aldehydes from the oxidation has to be followed carefully, since not all the functional groups in their unprotected form, suitable for cyclization, are stable under the condition of $NaIO_4$. Perform the $NaIO_4$ oxidation at neutral pH in the presence of a large excess of free methionine as a scavenger, to prevent oxidation of Met to Met(O). The oxidation rate increases as pH decreases, but side reactions occur at lower pH. The aldehyde may decompose, and the absence of air is necessary. Flushing with nitrogen or argon for 30 min results in an oxygen-free solution. For cyclizations that include the presence of free sulfhydryl groups, the reactions must also be carried out in a solution devoid of oxygen to avoid dimerization. Also, addition of thiols or trialkylphosphine to the solution prevents the formation of dimers. The cyclization reactions can be carried out in a final concentration of up to 20 mM without affecting the yield of the desired product, since the reactions usually are concentration-independent.

In the indirect approach where either linear or cyclic unprotected peptides are ligated to a MAP core matrix using carbonyl or thiol chemistry, the ligation reactions are also performed in an oxygen-free solution. Usually, the ligation is performed with a peptide concentration at 1.2- to 2-fold excess relative to core matrix. For the thiol alkylation reaction in thiol chemistry, iodoacetylated and bromoacetylated derivatives are known to be more reactive than the chloroacetylated derivative. However, the chloroacetylated derivative is more stable during the preparation of core matrix, especially during HF cleavage.

The peptide and nonpeptide bonds formed in MAP and cMAP are stable at physiological pH (pH 6 to 8) as well as at low pH during analytical and preparative HPLC. However, for long-term storage, the peptides must be stored as a dry powder at a maximum temperature of –20°C.

Anticipated Results

If synthesis of an eight-branched MAP with ~15 amino acid residues starts from 0.5 g resin with a resin loading of 0.1 mmol/g, then >0.5 g of crude MAP can be obtained. Its purity depends on both the peptide sequence and the method used for synthesis. Usually the purity of crude products will be >60%, and after purification ~40% to 50% can be recovered as purified MAP. This amount is usually more than sufficient for biological purposes. In general, the reaction should start with 0.3 to 0.5 g resin. For preparing cMAP using the direct approach, the overall yield can be up to 60% for cyclic peptides containing 17 and 24 amino acid residues, also starting with 0.5 g resin (loading is 0.1 mmol/g). In the direct approach, the average yield for MAP is between 50% and 60% using the ligation methods in Figure

BOWLING GREEN STATE UNIVERSITY LIBRARY

18.5.5. The yield of the pure cMAP system is ~30% when cyclic peptides ranging from 6 to 14 amino acids are used. However, the site and structure, as well as the excess and concentration of the peptides influence the obtained yield. Both methods for generating MAP and cMAP systems are applicable for mimetic proteins.

If HPLC of a crude MAP prepared by the direct approach shows multiple peaks without a major product, the complex may be difficult to purify, and the yield of MAP may not be satisfactory. In this case, the synthetic procedure (synthetic chemistry, protecting combination, coupling procedure, and/or cleavage conditions) should be modified. Also, the progress of the ligation reactions in the indirect approach is conveniently monitored by RP-HPLC (*UNIT 11.6*). If no product is formed, the peptides should be reanalyzed by mass spectrometry (Chapter 16) for the presence of nucleophilic and electrophilic moieties that have to react with each other. The peptide may even have to be resynthesized. Also, be aware of the formation of byproducts that can be generated from hydrolysis of the starting material at a given pH. Therefore, recheck the pH during the cyclization and assembling reactions.

Time Considerations

An automatic peptide synthesizer can assemble ~15 residues in one day by a rapid procedure using a 15-min cycle or in 2 days with the the normal cycle of ~1 hr. The synthesis of a MAP system with its peptide chain of 10 to 20 residues will usually take 1 to 2 days using the direct approach. Using a manual shaker for solid-phase peptide synthesis, assembly of as many as 6 to 12 amino acid residues onto the resin in one day is possible. The same MAP system can be prepared within 4 days by manual synthesis. Cleavage and subsequent purification can take from 2 days to 1 week, depending on the purity of the crude product as well as the required purity of the isolated MAP system. In preparing cMAP using the direct approach, 5 days should be added for the extra steps of cyclization, purification and characterization.

In the indirect approach for preparing MAP systems, both the peptide and core matrix are prepared and purified before ligation. Ligation of the peptide with the core matrix requires an additional reaction step and adds 2 to 3 days to the process. For cyclization of the linear unprotected precursors, 3 extra days are needed.

CHAPTER 19
Identification of Protein Interactions

INTRODUCTION

Protein interactions are intrinsic and vital to many cellular processes. In recent years many new techniques have been developed for the study of this important topic; the review by Phizicky and Fields (1995) provides an excellent general overview of this subject. This chapter describes biochemical, physical, and genetic methods that are used to detect specific protein interactions. A companion chapter in preparation will present a series of complementary methods that are used to provide quantitative information about protein interactions, such as the strength and kinetics of binding.

This chapter begins with brief overview of the analysis of protein interactions in which some of the basic kinetic and thermodynamic concepts are described (*UNIT 19.1*). This is followed by a presentation of one of the most widely used approaches for detecting protein interactions, the yeast two-hybrid/interaction trap system (*UNIT 19.2*). In this genetic method transcriptional activity is used as a measure of protein interaction.

In the technique of co-immunoprecipitation (*UNIT 19.4*), cell-free extracts are incubated with an antibody to a protein or an epitope tag in order to coprecipitate associated proteins. This approach is used to isolate multiprotein complexes that presumably were present in the intact cell.

In the technique of co-immunoprecipitation (*UNIT 19.4*), cell-free extracts are incubated with an antibody to a protein or an epitope tag in order to coprecipitate associated proteins. This approach is used to isolate multiprotein complexes that presumably were present in the intact cell.

Future plans for this chapter include units on a phage-based expression cloning system used to identify interacting proteins, and surface plasmon resonance (SPR), another useful method for discovery and detection of protein interactions that is gaining in popularity.

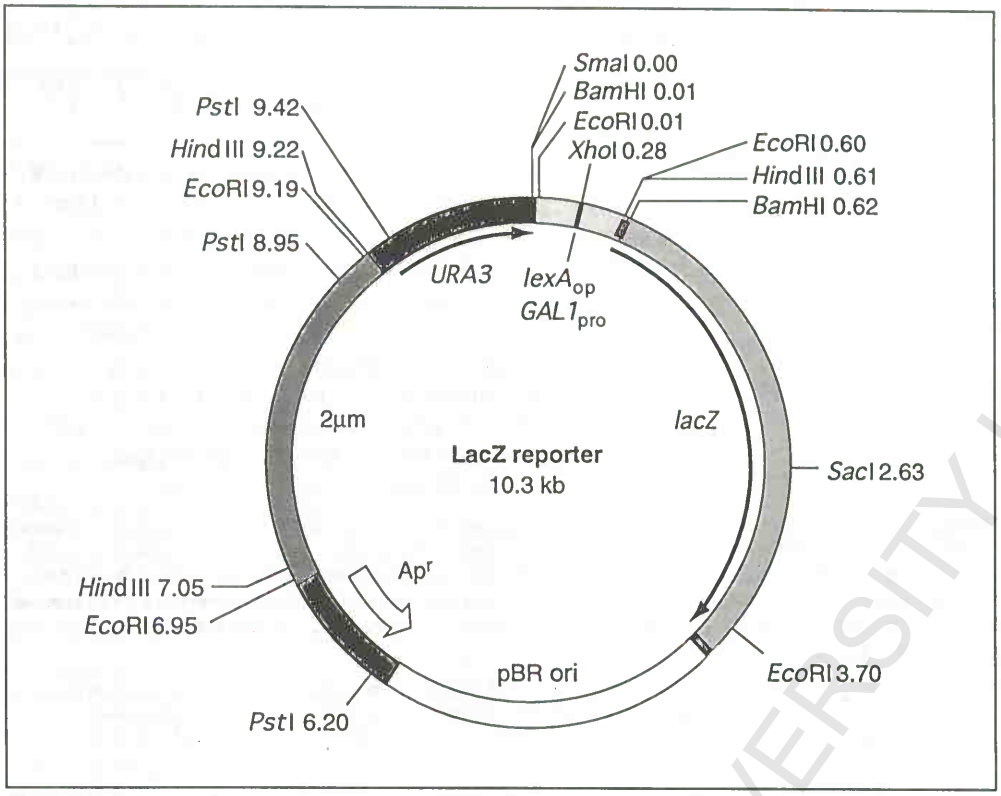

Figure 19.2.4 LacZ reporter plasmid. pRB1840, pJK103, and pSH18-34 are all derivatives of LR1Δ1 (West et al., 1984) containing eight, two, or one operator for LexA (*LexA*$_{op}$) binding inserted into the unique *Xho*I site located in the minimal *GAL1* promoter (*GAL1*$_{pro}$; 0.28 on map). The plasmid contains the *URA3* selectable marker, the 2µm origin to allow propagation in yeast, the ampicillin resistance (Ap^r) gene, and the pBR322 origin (ori) to allow propagation in *E. coli*. Numbers indicate relative map positions. In the recently developed derivatives, the ampicillin resistance gene (Ap^r) has been replaced with the chloramphenicol or kanamycin resistance genes (see Table 19.2.1 for details).

NOTE: All solutions and equipment coming into contact with cells must be sterile, and proper sterile technique should be used accordingly.

Transform yeast with the bait protein plasmid

1. Using standard subcloning techniques (e.g., Struhl, 1987), insert the DNA encoding the protein of interest into the polylinker of pEG202 (see Fig. 19.2.3) or other LexA fusion plasmid to make an in-frame protein fusion.

   The LexA fusion protein is expressed from the strong alcohol dehydrogenase (ADH) promoter. pEG202 also contains a HIS3 selectable marker and a 2µm origin for propagation in yeast. pEG202 with the DNA encoding the protein of interest inserted is designated pBait. Uses of alternative LexA fusion plasmids are described in Background Information.

2. Perform three separate lithium acetate transformations (*APPENDIX 4L*) of EGY48 using the following combinations of plasmids:

   pBait + pSH18-34 (test)
   pSH17-4 + pSH18-34 (positive control for activation)
   pRFHM1 + pSH18-34 (negative control for activation).

   Use of the two LexA fusions as positive and negative controls allows a rough assessment of the transcriptional activation profile of LexA bait proteins. pEG202 itself is not a good negative control because the peptide encoded by the uninterrupted polylinker sequences is itself capable of very weakly activating transcription.

BOSTON CENTRAL UNIVERSITY LIBRARY

Table 19.2.2 Interaction Trap Yeast Selection Strains[a]

Strain	Relevant genotype	Number of operators	Comments/description
EGY48[b,c,d]	*MATα trp1*, *his3*, *ura3*, lexAops-LEU2	6	*lexA* operators direct transcription from the *LEU2* gene; EGY48 is a basic strain used to select for interacting clones from a cDNA library
EGY191	*MATα trp1*, *his3*, *ura3*, lexAops-LEU2	2	EGY191 provides a more stringent selection than EGY48, producing lower background with baits with instrinsic ability to activate transcription
L40[c]	MATα *trpl*, *leu2*, *ade2*, GAL4, *lexAops-HIS34*, *lexAops-lacZ8*		Expression driven from *GAL1* promoter is constitutive in L40 (inducible in EGY strains); selection is for *HIS* prototrophy. Integrated *lacZ* reporter is considerably less sensitive than pSH18-34 maintained in EGY strains

[a]Interaction Trap reagents represent the work of many contributors: the original basic reagents were developed in the Brent laboratory (Gyuris et al., 1993). Strains for specialized applications have been developed by the following individuals: E. Golemis, Fox Chase Cancer Center, Philadelphia, Pa. (EGY48, EGY191); A.B. Vojtek and S.M. Hollenberg, Fred Hutchinson Cancer Research Center, Seattle, Wash. (L40). Specialized strains not yet commercially available can be obtained by contacting the Brent laboratory at The Molecular Sciences Institute, Berkeley, (510) 647-0690 or *brent@molsci.org*, or the Golemis laboratory, (215) 728-2860 or *EA_Golemis@fccc.edu*.

[b]Strains commercially available from Clontech.

[c]Strains commercially available from Invitrogen as components of a Hybrid Hunter kit; the kit also includes all necessary positive and negative controls (not listed in this table). See Background Information for further details on commercially available reagents.

[d]Strains commercially available from OriGene.

pSH18-34 contains a 2μm origin and a URA3 selectable marker for maintenance in yeast, as well as a bacterial origin of replication and ampicillin-resistance gene. It is the most sensitive lacZ reporter available and will detect any potential ability to activate lacZ transcription. pSH17-4 is a HIS3 2μm plasmid encoding LexA fused to the activation domain of the yeast activator protein GAL4. This fusion protein strongly activates transcription. pRFHM1 is a HIS3 2μm plasmid encoding LexA fused to the N-terminus of the Drosophila protein bicoid. This fusion protein has no ability to activate transcription.

3. Plate each transformation mixture on Glu/CM –Ura, –His dropout plates. Incubate 2 days at 30°C to select for yeast that contain both plasmids.

   Colonies obtained can be used simultaneously in tests for the activation of lacZ (steps 4 to 7) and LEU2 (steps 12 to 13) reporters.

Assay lacZ gene activation by β-galactosidase assay

4. Streak a Glu/CM –Ura, –His master dropout plate with at least five or six independent colonies obtained from each of the three transformations in step 3 (test, positive control, and negative control) and incubate overnight at 30°C.

   The filter assay described in Steps 5a to 7a (based on Breeden and Nasmyth, 1985) provides a rapid assay for β-galactosidase transcription. Alternatively, a liquid assay (APPENDIX 4L) or a plate assay (described in Steps 5b to 7b) may be used.

Perform filter assay for β-galactosidase activity:

5a. Lift colonies by gently placing a nylon membrane on the yeast plate and allowing it to become wet through. Remove the membrane and air dry 5 min. Chill the membrane, colony side up, 10 min at –70°C.

   Whatman 3MM filters can be cut to the size of the yeast plate as a more economical alternative to nylon membranes for performing lifts. In addition, two or three 5-min temperature cycles (–70°C to room temperature) can be used instead of a single cycle to promote better lysis; this may be worth doing if there is difficulty visualizing blue color.

ESU IASI / CENTRAL UNIVERSITY LIBRARY

Detection of Protein-Protein Interactions by Coprecipitation

Coprecipitation of proteins from whole-cell extracts is a valuable approach to test for physical interactions between proteins of interest. When a precipitating antibody is used, this method is referred to as co-immunoprecipitation. Coprecipitation can be used to study interactions between known proteins under a variety of conditions and as a means of identifying components of a complex. Coprecipitation may be the single method of choice, or may be used in combination with other methods that detect protein-protein interactions, such as two-hybrid analysis and copurification schemes (*UNIT 19.2*), and tests of physical associations using purified proteins.

This unit describes basic approaches to immunoprecipitating tagged proteins from whole-cell extracts. The approaches described can be adapted for other systems. In a typical experiment, as described here, cells are lysed and a whole-cell extract is prepared under nondenaturing conditions (see Strategic Planning). The protein is precipitated from the lysate with a solid-phase affinity matrix and the precipitate is tested for the presence of a second specifically associated protein (see Basic Protocol and Alternate Protocol). The approach can be used for native or epitope-tagged proteins for which antibodies are available, or for recombinant proteins that have been engineered to bind with high affinity to a molecule that can be coupled to a solid-phase matrix (see Strategic Planning). The presence of an associated protein is detected by separating the precipitated proteins by SDS-PAGE (*UNIT 10.1*) and then immunoblotting (*UNIT 10.10*) with a second antibody that recognizes the putative associated protein. Controls to test specificity of interaction are crucial (see Strategic Planning).

For additional background reading, the user should consult *UNIT 3.8* for a theoretical discussion of immunoprecipitation and Coligan et al. (1999) for principles of antibody production and immunoassays; see *UNIT 19.3* for approaches to tagging proteins; and see *APPENDIX 4L* and *UNITS 5.6-5.8* for transformation and propagation of yeast. For an in-depth review of immunoprecipitation techniques, see Chapter 11 of Harlow and Lane (1988). For an in-depth review of coprecipitation and other approaches to detect protein-protein interactions, see Phizicky and Fields (1995).

STRATEGIC PLANNING

Detecting the Proteins in Question

The first step is to generate reagents that detect the two proteins in the coprecipitate under nondenaturing conditions. If antibodies are available that can immunoprecipitate the proteins under nondenaturing conditions, then these can be used. Alternatively, the proteins can be differentially tagged in a variety of ways to allow their detection with commercially available antibodies or other affinity reagents. The tagged proteins are then introduced into the host organism using expression vectors. All tagged proteins must be assessed for function in vivo.

A frequently used option is to add a short peptide or epitope that is recognized by a commercially available high-affinity monoclonal antibody (mAb). The epitope is typically added at the amino or carboxyl terminus, although internal positions that do not disrupt function can also be used. Two frequently used epitopes are derived from influenza hemagglutinin protein (HA) and human c-Myc and are recognized by high-affinity mAbs (12CA5 and 9E10, respectively; Kolodziej and Young, 1991). Others, such as FLAG, are

BOSTON CENTRAL UNIVERSITY LIBRARY

also available (BioSupplyNet Source Book, 1999). The choice of epitope may be dictated by its amino acid composition. It is often useful to insert tandem copies of the epitope in order to increase sensitivity. The number of additional tandem copies can range widely, from one (Field et al., 1988) to several (e.g., three; Tyers et al., 1993) to many (e.g., nine; Feng et al., 1998).

Proteins can also be fused to small proteins or peptides that have high affinity to small molecules that can be attached to a solid support. This is a particularly valuable approach when the protein to be precipitated comigrates with immunoglobulin heavy or light chains in an SDS-polyacrylamide gel. Such alternative tagging methods include fusion to glutathione-*S*-transferase (to allow purification by a glutathione affinity matrix; *UNIT 6.6*) or maltose-binding protein (to allow purification by a maltose affinity matrix; *UNIT 5.1*). An excellent reference for identifying sources of commercially available antibodies and approaches to tagging proteins is the BioSupplyNet Source Book (1999). See Coligan et al. (1999) and Harlow and Lane (1988) for the generation and purification of specific antibodies. See Chapters 5, 6, and 7 of this manual for a discussion of tagging and expressing proteins.

Preparing Whole-Cell Extracts

The second step in a successful coprecipitation is generating whole-cell extracts that optimize the yield and activity of the proteins to be analyzed, using lysis buffer conditions that permit recognition of the proteins by the affinity matrix. The yield of total protein in a whole-cell extract is not always a reliable indicator of the relative yield and activity of specific proteins, so it is wise to verify both parameters at the onset of an experiment before proceeding with the coprecipitation. Yield and activity can be affected by a number of factors (see Chapter 10; see Harlow and Lane, 1988). Small variations in the relative amounts of salt and detergents in the lysis buffer can have large effects on yield and activity, as can the speed and efficiency of cell breakage. Both factors are particularly important for less soluble proteins that associate with macromolecular structures such as membranes or cytoskeleton. In addition, global inhibition of proteolysis through the inclusion of multiple classes of protease inhibitors may be essential.

Methods for preparing whole-cell extracts from yeast (*UNITS 5.6-5.8*), *Escherichia coli* (*UNIT 6.2*), insect cells (*UNIT 5.12*), and mammalian cells (*UNITS 5.9 & 5.10*) can be found elsewhere in this manual, and specifics will not be discussed here. In general, the lysis buffer conditions are not very different from the coprecipitation conditions. It is recommended that the investigator begin by comparing small-scale extract preparations that vary the amount of salt and nonionic detergent. As a starting point, a basic lysis buffer might contain the following components.

Basic components. Basic components include a buffering agent (such as 50 mM Tris·Cl, pH 7.5), a small amount of nonionic detergent (such as 0.1% [v/v] Triton X-100), salt (such as 100 mM NaCl), a reducing agent (such as 1 mM DTT), and 10% (v/v) glycerol as stabilizer.

Protease inhibitors. Protease inhibitor cocktails are described here in *UNIT 5.8* and are also commercially available. A reasonable starting point would be to include 5 µg/ml each of chymostatin, pepstatin A, leupeptin, and antipain, as well as 1 mM phenylmethysulfonyl fluoride and 1 mM benzamidine.

Chelating agents. EGTA (~15 mM) is commonly included to chelate divalent metal ions that are essential for metalloprotease activity. Because EGTA also inhibits other metal-dependent enzymes, it may be omitted, combined with the addition of a needed metal ion, and/or substituted with EDTA.

PCU IAST CENTRAL UNIVERSITY LIBRARY

Phosphatase inhibitors. If the phosphorylation state of the proteins in question is important, a mixture of phosphatase inhibitors should also be included in the lysis buffer. A starting mixture could contain 2.5 mM each meta- and ortho-vanadate, 10 mM NaF, and 10 mM β-glycerol phosphate.

Simple modifications of this initial buffer include varying the amount of NaCl (from 0 to 500 mM) and of Triton X-100 (from 0% to 1%). The investigator may choose to compare different means of breaking the cells (for example, glass-bead breakage versus liquid nitrogen/grinding methods for yeast cells; *UNITS 5.6-5.8*).

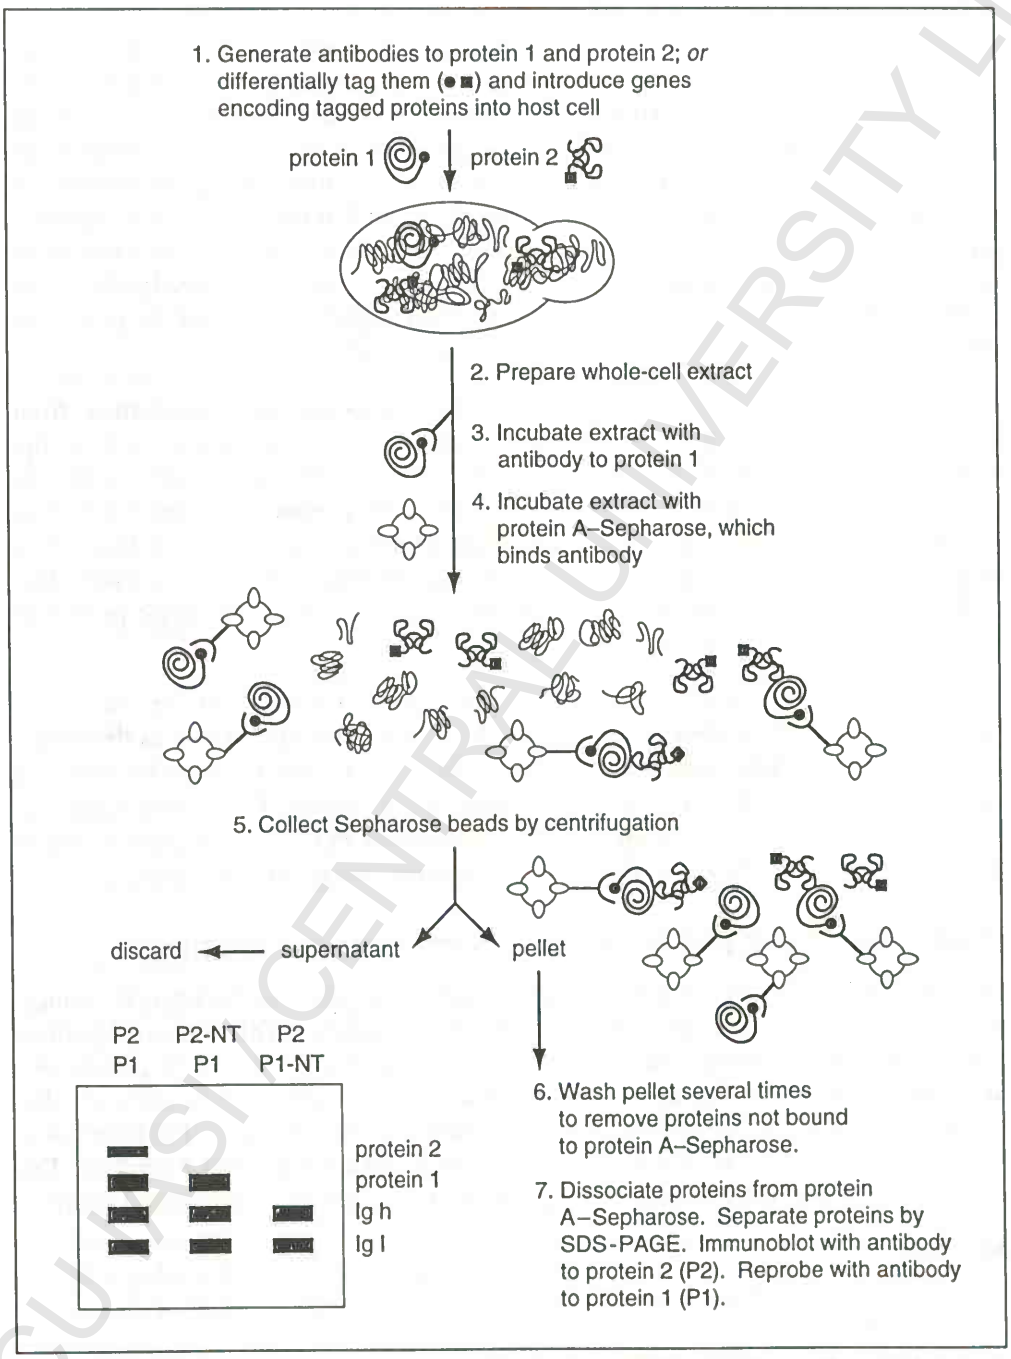

Figure 19.4.1 Flow chart for the coprecipitation of two proteins that have been differentially tagged and introduced into the host organism. Ig h and Ig l, immunoglobulin heavy and light chains; NT, no tag.

BCU IASI CENTRAL UNIVERSITY LIBRARY

Total protein concentration in the whole-cell extract is generally assayed by using the Bio-Rad protein assay and calculating protein concentration (*UNIT 3.4*). Extracts should be tested for the amount of each specific protein by immunoblot analysis (*UNIT 10.10*), analyzing 25 to 75 μg of total protein. In general, it is best to test for the presence of a second established protein (such as a housekeeping enzyme, cytoskeletal or ribosomal protein, or a previously defined component in the pathway being studied) as an internal control for normalization and as a positive control for the immunoblot. The amount of specific protein in the whole-cell extract is compared to the amount that is recovered by precipitation with an affinity matrix.

Control Tests for Specificity of Interaction

Controls are essential to verify that the antibodies and protein-protein interactions are specific. Proper controls are simplest to set up when the proteins are differentially tagged. In this instance, two parallel extracts are prepared from strains that contain each protein lacking the tag in the presence of the second tagged protein. An example is shown in the idealized gel in Figure 19.4.1, which includes lanes containing untagged protein 1 + tagged protein 2 and tagged protein 1 + untagged protein 2. If the antibodies are specific, untagged protein 1 will not immunoprecipitate. The presence of untagged protein 1 in the immunoprecipitate will indicate that it binds the affinity matrix nonspecifically. If the interaction between proteins 1 and 2 is specific, then tagged protein 2 will be present in the immunoprecipitate of tagged protein 1, but not in its absence.

If antibodies to native proteins are used, it is necessary to compare extracts made from strains harboring deletions of the proteins in question to test for the specificity of the antibody and the interaction. However, this is obviously possible only if the deletions do not cause inviability. If deletion mutations cannot be used, a common approach is to show that the preimmune serum or an antibody not known to be specific to either of the proteins in question does not coprecipitate them in a parallel experiment. However, the latter two controls do not rule out the possibility that the antibody is precipitating the protein in question through an indirect association.

It is also essential to compare the amount of coprecipitated protein with the amounts of the two proteins in question in the whole-cell extract. This allows one to determine whether apparent differences in the ability of the two proteins to coprecipitate are a secondary consequence of the relative abundance of the proteins. This control is particularly important when an interaction has been established and the investigator wishes to search for regulatory changes in association apart from changes in abundance.

BASIC PROTOCOL

COPRECIPITATING PROTEINS WITH PROTEIN A/G–SEPHAROSE

Once the conditions of extract preparation have been established (see Strategic Planning), the next step is to test for coprecipitation of the specific proteins. This protocol describes a standard coprecipitation procedure that uses an antibody coupled to protein A–Sepharose or protein G–Sepharose. An alternative coprecipitation method that uses GST coupled to glutathione-agarose is also provided (see Alternate Protocol). It is essential to keep all buffers and tubes cold by using an ice bath and a refrigerated centrifuge. The conditions of coprecipitation match the conditions of the lysis buffer described above.

Materials

Whole-cell extract (see Strategic Planning)
Antibody
Co-immunoprecipitation buffer (see recipe)
5 M NaCl (*APPENDIX 2E*)

PCU IASI CENTRAL UNIVERSITY LIBRARY

Protein A/G–Sepharose slurry (see recipe)
2× sample buffer for SDS-PAGE (*UNIT 10.1*)

Test tube rotator
20-ml syringe and 18-G needle
Hamilton syringe

Additional reagents and equipment for SDS-PAGE (*UNIT 10.1*) and immunoblotting (*UNIT 10.10*)

1. Prepare duplicate samples in microcentrifuge tubes on ice:

   0.5 to 1 mg whole-cell extract
   1 µg antibody
   5 M NaCl to equalize at 100 mM NaCl
   Co-immunoprecipitation buffer to 0.5 ml final volume.

   Adjust buffer if necessary for activity of the protein in question (see Strategic Planning, discussion of chelating agents).

2. Invert tube gently several times and incubate on ice for 90 min with occasional tube inversion.

   It is recommended that the investigator begin with a 90-min incubation. However, this incubation step can be shortened or lengthened.

3. Microcentrifuge 10 min at maximum speed, 4°C, to pellet nonspecific aggregates. Transfer supernatant to a new microcentrifuge tube.

4. Add 50 µl of protein A– or protein G–Sepharose slurry (25 to 30 µl bead volume). Be sure to evenly suspend the slurry before distributing it to the samples.

   Protein A has been used more frequently for historical reasons; however, protein G binds a broader range of Ig subtypes at higher efficiency.

5. Rotate tube gently at 4°C for 30 to 60 min.

   Rocking is much less efficient and should be avoided.

6. Gently pellet protein A/G–Sepharose by centrifuging 30 sec at 1000 rpm in a tabletop centrifuge, 4°C.

7. Wash pellet three times with 1 ml co-immunoprecipitation buffer. For each wash, gently invert tube three times before pelleting. After each pelleting, use a 20-ml syringe with an 18-G needle to aspirate and remove supernatant.

   It may be possible to omit the costly protease inhibitors from the buffer at this stage, but this has not been attempted to date.

8. Aspirate as much liquid as possible from the final without touching the beads and add 25 µl of 2× sample buffer.

   If desired, samples containing sample buffer can be frozen up to several months at –80°C prior to SDS-PAGE. In this case the buffer should be prepared with sterile stock solutions and made with 1 mM sodium azide included.

9. Prepare for SDS-PAGE analysis by boiling for 5 min, vortexing, and microcentrifuging briefly to pellet beads. Use a Hamilton syringe to load eluates onto an SDS-polyacrylamide gel, arranging duplicate samples to allow preparation of duplicate blots. Separate by electrophoresis (*UNIT 10.1*).

   A Hamilton syringe works well to remove the eluate from the beads during loading.

BCU MAIN CENTRAL UNIVERSITY LIBRARY

10. Immunoblot duplicate samples separately with antibodies for each of the two proteins (*UNIT 10.10*). Be sure to include aliquots of the whole-cell extract for comparison and as a positive control for the immunoblot.

Each immunoblot can be reprobed with the antibody to the other protein.

ALTERNATE PROTOCOL

COPRECIPITATING A GST FUSION PROTEIN

GST fusion proteins may be coprecipitated by following the co-immunoprecipitation procedure (see Basic Protocol) with the modifications outlined below. This procedure might be used when the protein in question comigrates with immunoglobulin heavy or light chain in an SDS-PAGE gel or if the antibodies being used precipitate too many cross-reacting proteins, such as the protein being tested for association. Furthermore, it is possible to dissociate the purified GST fusion from the solid-state glutathione resin under gentle conditions through the use of imidazole. The approach is also useful in that it will increase the size of the protein sufficiently that this size increase can be used as a diagnostic feature in analyzing complexes.

Additional Materials (also see Basic Protocol)

Glutathione-agarose or glutathione-Sepharose slurry (see recipe)

1. Prepare duplicate samples as described for protein A/G–Sepharose (see Basic Protocol, step 1), omitting antibody.
2. Microcentrifuge 10 min at maximum speed, 4°C, to pellet nonspecific aggregates. Transfer supernatant to new microcentrifuge tube.
3. Add 30 µl glutathione-agarose or glutathione-Sepharose slurry (25- to 30-µl bead volume). Be sure to evenly suspend the slurry before distributing it to the samples.
4. Rotate the sample, pellet and wash glutathione-agarose/Sepharose, and perform SDS-PAGE and immunoblot analysis (see Basic Protocol, steps 5 to 10).

REAGENTS AND SOLUTIONS

Use deionized, distilled water in all recipes and protocol steps. For common stock solutions, see APPENDIX 2E; for suppliers, see SUPPLIERS APPENDIX.

Co-immunoprecipitation buffer

50 mM Tris·Cl, pH 7.5 (*APPENDIX 2E*)
15 mM EGTA
100 mM NaCl
0.1% (w/v) Triton X-100
Store at 4°C
Immediately before use add:
1× protease inhibitor mix (see recipe)
1 mM dithiothreitol (DTT)
1 mM phenylmethylsulfonyl fluoride (PMSF; from fresh 250 mM solution in 95% ethanol)

If necessary for activity of the protein of interest, a divalent cation may need to be included in the buffer and EGTA omitted (as for extraction buffer; see Strategic Planning, discussion of chelating agents).

The protease inhibitor mix, PMSF, and DTT should be added fresh at the time of experimentation. The mixture without those components can be stored for months at 4°C with the addition of 1 mM sodium azide. PMSF is labile in aqueous buffer and should be added at the last minute.

BCU IASI - CENTRAL UNIVERSITY LIBRARY

Glutathione-agarose or glutathione-Sepharose slurry

Swell 1.5 g glutathione-agarose or glutathione-Sepharose beads (e.g., Pierce, Sigma) in 30 ml of 50 mM Tris·Cl, pH 7.5 (*APPENDIX 2E*), for 1 to 2 hr on ice. Pellet beads by gravity or very gentle centrifugation (1 min at 1000 rpm in a tabletop centrifuge) and then wash four times with co-immunoprecipitation buffer (see recipe) that lacks protease inhibitor mix and contains 1 mM sodium azide. Resuspend beads in 15 ml of this buffer to yield a final slurry concentration of ~100 mg/ml. Store at 4°C (stable for months).

This recipe can be scaled up or down.

Protease inhibitor mix, 1000×

Dissolve in DMSO:
5 mg/ml chymostatin
5 mg/ml pepstatin A
5 mg/ml leupeptin
5 mg/ml antipain
Store in aliquots up to 1 year at –20°C

Protein A/G–Sepharose slurry

Swell 1.5 g protein A– or protein G–Sepharose beads (e.g., Pierce, Sigma) in 30 ml of 50 mM Tris·Cl, pH 7.5 (*APPENDIX 2E*), for 1 to 2 hr on ice. Pellet beads by gravity or very gentle centrifugation (1 min at 1000 rpm in a tabletop centrifuge) and then wash four times with co-immunoprecipitation buffer (see recipe) that lacks protease inhibitor mix and contains 1 mM sodium azide. Resuspend beads in 15 ml of this buffer to yield a final slurry concentration of ~100 mg/ml. Store at 4°C (stable for months).

This recipe can be scaled up or down.

COMMENTARY

Background Information

Coprecipitation is a powerful and simple approach to test for a physical interaction between proteins. There are many reasons to incorporate coprecipitation into a study. First, as a form of protein affinity chromatography, the method may be sensitive enough to detect weak associations that do not withstand the rigors of standard purification methods involving substantial dilution of the initial cell extract. Second, coprecipitation tests for associations between proteins within the milieu of a whole-cell extract, where the proteins are present at native concentration in a complex mixture of other cellular components. This feature makes it an important partner to two-hybrid methods and direct tests of interactions using purified proteins, because it provides a way to verify that a positive interaction reflects a true in vivo association. For example, nonphysiological interactions can be detected when purified proteins are present at too elevated a concentration. A falsely positive interaction between two proteins can also arise in a two-hybrid test when protein domains are inappropriately exposed due to altered folding. In addition, not all proteins are amenable to two-hybrid analysis; a negative result may mask a true association.

Nevertheless, a word of caution is in order. The ability to coprecipitate two proteins from a cellular extract is not proof that a particular interaction normally takes place in vivo. Additional experiments are needed to argue that a given interaction is not the result of mixing cell contents during extract preparation. Such evidence could include colocalization of the proteins or demonstration of functional relatedness.

When performing coprecipitation, it is important to precipitate from both directions (i.e., individually precipitating protein 1 and protein 2, and testing for the presence of protein 2 and protein 1, respectively). This is important in that it can provide further verification of an interaction between the proteins. It is also important because it is possible the interaction will only be detected in one direction. An inability to detect an interaction in one direction could be due to a variety of factors including obstruction of an interaction by the binding of

BOSTON UNIVERSITY LIBRARY

the antibody or other affinity agent, or differences in pool size representation of each protein. For example, protein 1 may bind to many proteins besides protein 2, while most of protein 2 binds to protein 1. In this scenario, it would be anticipated that detection of their association will be most efficient when protein 2 is precipitated.

Critical Parameters and Troubleshooting

It is important to vary conditions of both the extract preparation and the coprecipitation to determine what is optimal. When starting from scratch, it is most prudent to use a range of lysis and precipitation conditions from less to more stringent in terms of the amount of salt and nonionic detergent. When no interaction is detected, it is worthwhile to use less stringent conditions (reduced salt with little or no nonionic detergent). In addition, it may be necessary to avoid any dilution of the whole-cell extract. This can be done by adding the protein A/G–Sepharose directly to the extract after an initial clarification centrifugation and by using smaller wash volumes. Depending on the strength and nature of the interaction, the precipitation can be done in the presence of a mixture of detergents that includes ionic detergents (for example, 1% Triton X-100, 0.5% deoxycholate, 0.1% SDS), similar to that described in RIPA buffer (*UNIT 3.8*).

In addition, it may be necessary to increase the expression levels of the proteins in question to be able to readily detect them by coprecipitation. A range of expression levels is recommended, because a level that is too high can lead to unregulated interactions (Feng et al., 1998). Alternatively, one can scale up the coprecipitation and use more than 0.5 to 1 mg of whole-cell extract (Feng et al., 1998). Here, the limiting factor is the concentration of the extracts, which must be high enough to allow the volume of the coprecipitation mixture to remain low. Larger-scale extract preparations may be necessary to generate more concentrated extracts. Finally, in cases of failure due to low abundance of the proteins in the host organism, one can overexpress a tagged version of one of the two proteins in the same or another host (such as *E. coli*), concentrate this protein by preimmobilization on an appropriate affinity matrix, and then incubate the affixed protein with extracts from the host organism.

The most important objective in these experiments is to generate as great a signal-to-noise ratio as possible and avoid problems of background. A variety of parameters can be changed to enhance the co-immunoprecipitation. Optimization of the precipitating antibody is one possibility. Protein A–Sepharose and protein G–Sepharose should give results comparable to anti-Ig serum. However, direct coupling of the antibody to Sepharose may lead to lower background and more quantitative precipitation. In addition, varying the ratio of antibody to whole-cell extract and the total amount of whole-cell extract is strongly suggested to determine the optimal amount of antibody that gives the most precipitation with the least amount of background. Affinity purification of the antibody may be necessary if the antibody immunoprecipitates additional cross-reacting proteins.

Additional approaches can be taken to minimize background. First, better clarification of the cell extract can be achieved by precentrifugation at 100,000 × *g*. These extracts can be directly used for coprecipitation without an intervening freezing step, which can increase the amount of protein precipitation. Second, both the lysis buffer and the coprecipitation buffer can be supplemented with 1% BSA to reduce nonspecific binding to the affinity matrix. Third, the whole-cell extract can be preincubated with protein A/G–Sepharose to remove nonspecific proteins that bind to the solid support. Fourth, the amount of salt and detergent can be increased in both the coprecipitation and the washes to reduce nonspecific binding. Fifth, increasing the number of washes may also help, although it may reduce the amount of specific protein that remains associated. Sixth, the expression levels of the proteins in question can be increased to generate a stronger signal that is above background binding. Alternatively, it may be possible to produce a whole-cell extract that is enriched for the proteins in question (e.g., by preparing a nuclear extract if the proteins are known to be in the nucleus). In instances where one of the proteins binds nonspecifically to Sepharose, the substitution of an agarose-based affinity matrix may help solve the problem. Finally, it may be necessary to generate a different set of reagents to precipitate the proteins in question (i.e., different antibodies and/or protein tag).

Anticipated Results

Provided suitable antibodies are available to the proteins in question and the physical interaction is stable under the coprecipitation conditions, it should be possible to detect an interaction between two proteins.

PCU IAS CENTRAL UNIVERSITY LIBRARY

Time Considerations

Once the extracts are prepared, coprecipitation can be done within 3 to 4 hr, yielding samples ready to load on a gel for SDS-PAGE and immunoblot analysis.

CHAPTER 20
Quantitation of Protein Interactions

INTRODUCTION

The highest level of protein structure is quaternary structure, formed by the noncovalent association of protein subunits. Usually the associating protein subunits have a folded, or tertiary, structure, although there are cases where unfolded proteins with only secondary structure directly associate to form folded multisubunit complexes (e.g., trimeric glucagon). Protein complexes can range from simple symmetrical homodimers formed of identical subunits to highly complex multisubunit structures such as viral capsids.

Protein-protein interactions are important, indeed vital, to many biological events and processes. Analysis of interactions between proteins and detailed analysis of molecular interfaces—generally done in vitro using isolated proteins—are the bases for understanding many biological processes. A number of biochemical and biophysical techniques can be applied to study specific interactions involving proteins. This information, together with high-resolution structural information obtained by X-ray crystallography and NMR (Chapter 17), can provide an understanding of the molecular basis of these interactions.

Methodologies for studying the identification and quantitation of protein interactions have become so important that the editors of this volume have decided to devote two chapters to these techniques. In Chapter 19, the emphasis is on the detection of specific protein interactions; in this chapter the material is more concerned with quantitative aspects—e.g., the measurement of binding strengths and rates of binding. Quantitation of binding is usually performed using biophysical techniques such as gel filtration, equilibrium dialysis, large-zone analytical size-exclusion chromatography (SEC), and titration microcalorimetry, to name a few; these techniques are reviewed in *UNIT 20.1*. Some of these methods rely on sophisticated equipment such as the analytical ultracentrifuge. It is recognized that many laboratories will not own such instruments, so the first units covering each method will be extended overviews designed both to supplement the information in the general chapter overview and to provide investigators with enough background to both follow the published literature and, if necessary, intelligently seek collaboration. These overviews will be complemented by actual experimental protocols to be published in future supplements.

In this vein, then, comes *UNIT 20.2*, the first extended overview. This unit discusses the measurement of protein interactions by optical biosensors (including the popular Biacore instrumentation). It includes a Strategic Planning section on how to proceed with an experiment—depending on whether the binding will be steady-state, kinetic, or competitive—and information on sample preparation, analysis of results, and troubleshooting of suboptimal experimental results. Other extended overviews currently in preparation will cover titration microcalorimetry, analytical centrifugation (equilibrium and sedimentation-velocity approaches), and size-exclusion chromatography, among others.

Overview of the Quantitation of Protein Interactions

The biological function of many (and perhaps most) proteins involves reversible interactions with other proteins, nucleic acids, or other nonprotein ligands. Such interactions play many different roles in a wide range of cellular processes. A few examples are: (1) storing or transporting key metabolites (e.g., O_2 storage by myoglobin); (2) forming and maintaining the quaternary structure of multisubunit enzymes; (3) specific binding and recognition events (antigen-antibody, hormone-receptor, transcription factor–promoter); and (4) self-assembly of large structures (e.g., microtubules or chromatin). Thus the quantitative characterization of such interactions represents an important part of understanding the function of such proteins and their role in these cellular events.

The two fundamental properties that characterize any binding interaction are the stoichiometry (how many moles of each reactant combine to form the product) and the binding strength. The binding strength or "affinity" of the interaction is usually quantitatively expressed through either the equilibrium association constant, K_a, or its inverse, the dissociation constant, K_d, which for a reaction nA + mB $\leftrightarrow$ A_nB_m are defined by:

$$K_a = \frac{[A_nB_m]}{[A]^n[B]^m}$$

$$K_d = \frac{[A]^n[B]^m}{[A_nB_m]}$$

The choice of using K_a or K_d is largely a matter of personal preference. The concentration terms in Equation 20.1.1 may be expressed in any concentration units, but molar units are generally preferred. The binding strength can also be characterized by the change in Gibbs free energy for the reaction, ΔG, which is related to the equilibrium constant through the relation $\Delta G = RT\ln(K_d) = -RT\ln(K_a)$, where R is the gas constant and T is the absolute temperature. It should always be remembered that such energy changes are not absolute, but are always relative to some reference state, which conventionally is taken as a 1 M solution of each reactant (and hence the preference for equilibrium constants in molar units).

The various experimental methods differ considerably in their ability to determine the stoichiometry and/or K_d as well as in the range of values they can measure. Table 20.1.1 lists the techniques that will be covered in this unit and summarizes the type of information each gives and the approximate range of K_d values it can measure. The good news is that there are often several of these methods that can be appropriately applied to a given system. Moreover, the continued emergence of new and improved instruments, software, and protocols broadens the choices and reduces the time, effort, and/or amount of material required for obtaining the desired information.

SOME COMMENTS ON TECHNIQUES

Most of the methods in this unit detect binding interactions through a change in mass as binding occurs. In addition to mass spectrometry itself, this group includes sedimentation equilibrium (analytical and micropreparative), surface plasmon resonance (SPR), size-exclusion chromatography (SEC) with on-line light scattering, and chemical cross-linking. Techniques such as large-zone analytical SEC, sedimentation velocity, and some of the electrophoresis methods, while not strictly mass-based since the changes in hydrodynamic properties or mobility are related to changes in molecular shape as well as mass, can nonetheless reasonably be grouped with the true mass techniques. Changes in spectroscopic properties such as fluorescence polarization (Heyduk et al., 1996) may also be related to mass changes and hence certain spectroscopic approaches also belong in this group.

As might be expected, methods that are members of this group are usually capable of determining stoichiometry, but some of these methods are not necessarily able to measure the equilibrium constant. For example, mass spectrometry, cross-linking, and light scattering/SEC are generally excellent at determining stoichiometry, but the amount of the higher-mass complex that they detect may not accurately reflect its proportion at equilibrium. It is also important to remember that some methods, such as sedimentation velocity and light scattering/SEC, involve dynamic physical separa-

Table 20.1.1 Summary of Characteristics for Some Important Methods for Characterizing Protein Interactions

Technique[a]	Basis for detection	Binding properties measured (and range of K_d)	Minimum sample mass or volume needed[b]	Typical analysis time[c]	References	Comments
Mass spectrometry	Change in molecular mass	Stoichiometry	0.001 µg; <1 µl	15 min	Loo, 1997; Roepstorff, 1997; Farmer and Caprioli, 1998	May not detect weaker interactions; very helpful prelude to centrifugation methods, especially for glycoproteins
Chemical cross-linking	Change in molecular mass	Stoichiometry	5 µl[d]	30 min + readout	Loster and Josic, 1997; Kunkel et al., 1981	Useful and fairly simple approach to determining quaternary structure and stoichiometry
SEC with light scattering	Change in solution mass	Stoichiometry	100 µg (20 kDa); 10 µg (200 kDa); 5 µl	30 to 60 min	Harding et al., 1992; Wen et al., 1996	Gives true mass, independent of molecular shape
Equilibrium dialysis and gel permeation, ultrafiltration, gel chromatography (Hummel-Dreyer)	Partitioning of free and bound ligand	Stoichiometry (K_d ~10^{-1} to 10^{-13} M)	10 µl[d]	15 min to 24 hr + readout	Andreu, 1985; Kido et al., 1985; Sophianopoulos and Sophianopoulos, 1985; Sebille et al., 1990	"Low tech" and often labor-intensive, but still very useful and adaptable
Large-zone analytical SEC	Change in hydrodynamic size	Stoichiometry (K_d ~10^{-4} to 10^{-13} M)	1000 µl[d]	30 to 60 min + readout	Ackers, 1973; Valdes and Ackers, 1979; Nenortas and Beckett, 1994	Wide range of potential on-line or off-line detection methods; may be labor-intensive depending on degree of automation
Micropreparative analytical ultracentrifugation (sedimentation equilibrium)	Change in solution mass	Stoichiometry (K_d ~10^{-3} to 10^{-13} M)	100 µl[d]	12 to 24 hr + readout (4 to 6 samples per rotor)	Darawshe et al., 1993, 1995	Requires only preparative centrifuges; fewer data points and more labor-intensive than on-line instruments, but much greater specificity and sensitivity through off-line detection

BGU IASI CENTRAL UNIVERSITY LIBRARY

Spectroscopic methods	Change in spectroscopic property	Molar ratio stoichiometry (possibly); conformational changes (K_d ~10^{-5} to 10^{-11} M)	—[e]	0.2 to 2 hr	Oberfelder and Lee, 1985; Heyduk et al., 1996; van Holde et al., 1998	Applicability depends on nature of protein and/or ligand; chromophore label may be required
Titration microcalorimetry	Heat release or uptake	Molar ratio; ΔH; Δc_p (K_d ~10^{-3} to 10^{-9} M)	100 µg; 2000 µl	3 hr	Bundle and Sigurskjold, 1994; Fisher and Singh, 1995; Doyle, 1997	Universal signal; works well for small molecules; useful additional thermodynamic information
Sedimentation equilibrium (in analytical ultracentrifuge)	Change in solution mass	Stoichiometry (K_d ~10^{-3} to 10^{-9} M)	10 µg; 100 µl	12 to 24 hr per rotor speed (9 to 21 samples)	Rivas and Minton, 1993; Laue, 1995; Schuster and Toedt, 1996	Powerful method when there is a significant change in mass; much more accessible with modern hardware and software
Sedimentation velocity (in analytical ultracentrifuge)	Change in sedimentation coefficient	Stoichiometry; conformational changes (K_d ~10^{-3} to 10^{-9} M)	10 µg; 400 µl	2 to 5 hr (3 to 7 samples)	Schuster and Toedt, 1996; Lobert et al., 1997; Stafford, 1997	Newer software makes data analysis fast and user-friendly; generally not as good as sedimentation equilibrium for K_d
Surface plasmon resonance	Change in mass bound to surface	Stoichiometry; kinetics (K_d ~10^{-3}-10^{-13} M)	0.01 µg; 100 µl	15 to 30 min (1 analyte, up to 4 surfaces)	Myszka, 1997; Schuck, 1997; Morton and Myszka, 1998	Broad range of K_d; high throughput; fairly insensitive to contaminants; potential problems from surface coupling

[a]Techniques that primarily give information about stoichiometry are listed first, followed by those with good quantitation of binding affinity, with the latter arranged roughly in order of cost and complexity of the instrumentation.

[b]Approximate minimum sample mass (detection limit) and minimum sample volume. For weaker interactions the sample requirement is often dictated more by the volume requirement, since it is necessary to have this volume of solution at a concentration high enough to saturate the interaction. These figures will vary by an order of magnitude or more depending on the equipment and exact protocol employed.

[c]This is the approximate time needed to carry out the experiment. For methods in which more than one sample may be run simultaneously, the number of samples is noted in parentheses. For methods in which the readout of concentration is performed separately (e.g., by ELISA or scintillation counting) the time for that step is not included.

[d]Required mass depends on detection method; for radiolabeling, ELISA, or fluorescence detection the mass required may be extremely small.

[e]Required mass and volume depend on detection method.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

tion of components and are not true equilibrium methods. With these methods, the results may depend on the *rates* of association-dissociation as well as the equilibrium constant. For relatively weak interactions with relatively fast kinetics, the band or boundary that is seen is a so-called "reaction boundary" and does not necessarily correspond to any single species or any particular stoichiometric complex. This complication does not apply to sedimentation equilibrium, even though there is some separation of components, because association-dissociation equilibrium is maintained at every position in the centrifuge cell. Large-zone analytical SEC also can be regarded as a true equilibrium technique because the concentration and composition of the plateau region matches what was present before the sample was loaded onto the column.

One common drawback of these methods based on mass is that they may be insensitive to the binding of peptides or other ligands having a mass that is small compared to that of the protein. Under certain circumstances it may therefore be desirable to deliberately increase the mass of such ligands. For example, a peptide might be fused with a larger polypeptide or a small ligand modified by adding a defined polyethylene glycol polymer. The caveat here is, of course, that such modifications must not interfere with binding, so this approach usually requires knowledge that some region of the ligand is *not* important for binding.

Surface Plasmon Resonance

SPR-based sensors have several unique characteristics relative to the other mass-based methods, which warrant some further discussion. First, SPR is unique among these methods in that the kinetics of the association and dissociation events can be measured explicitly, and this kinetic information can provide insights that may be difficult to obtain from equilibrium information alone. SPR actually provides two fairly different approaches to characterizing the binding affinity. In one approach, the equilibrium association constant is determined from the kinetic data by first determining the association and dissociation rates and then calculating their ratio. The alternative approach involves exposing the reactant solution to the measurement surface for a long time to allow the binding to reach equilibrium. The magnitude of this binding signal is then analyzed as a function of reactant concentration to obtain the equilibrium constant, in a fashion similar to other equilibrium methods.

Another significant difference in SPR is that one of the reactants is coupled to a surface. In principle, this should not matter, provided that this coupling does not produce steric hindrance or involve chemically modifying residues important for the interaction being studied. Random coupling methods, however, have the potential for producing a range of orientations and binding properties, so coupling via a specific site and/or in a specific orientation is preferred for detailed quantitative studies. Further, surface binding can be fundamentally different than solution binding if there is the potential for more than one molecule on the surface to simultaneously interact with a single analyte molecule in solution. A failure to properly consider and treat multivalent interactions on the surface can, and has, led to errors of many orders of magnitude in binding constants obtained by SPR (Kalinin et al., 1995; Ladbury et al., 1995). Thus independent knowledge of the reaction stoichiometry is quite helpful for the design and interpretation of SPR experiments. With current procedures (Schuck, 1997; Morton and Myszka, 1998; *UNIT 20.2*) such problems arising from multivalent interactions, as well a number of other potential artifacts in SPR, can usually be avoided.

SPR is generally an excellent tool for studying protein-ligand interactions and interactions between two different proteins, but the required surface coupling limits its utility for characterizing protein self-associations. Lastly, it should not go unmentioned that one of the great virtues of SPR methods is that the amount of material required is usually quite small, particularly for the component bound to the measurement surface.

Analytical Ultracentrifugation (Sedimentation Equilibrium and Sedimentation Velocity)

Once relegated to a few dedicated specialists, with improved hardware and automation this technique is again becoming widely used and more accessible to nonspecialists, and the quantity of sample required is also reduced. Among the strengths of analytical ultracentrifugation are that the governing principles are simple and well understood, and the theory and practice has been developed over many years.

Sedimentation equilibrium has many virtues (and a long history of success) for detailed studies of complex interactions, among which are: (1) it is a true solution equilibrium method; (2) it can cover a broad range of concentrations (~5 μg/ml to >100 mg/ml for

BCU IASH CENTRAL UNIVERSITY LIBRARY

proteins); (3) there are few restrictions on the choice of solvents; and (4) it can be applied over a fairly wide temperature range (0° to 40°C for the Beckman XL-I). Its primary drawback is that reaching equilibrium typically requires 12 to 24 hr for a 3-mm solution column, so the throughput is fairly low (but 9 to 21 samples can be run simultaneously), and some proteins are not sufficiently stable over these long time periods. The use of even shorter solution columns (<1 mm) with interference optics reduces equilibration time to a few hours or less, but results in fewer data points and less overall accuracy. This short-column approach is excellent for determining stoichiometry, for survey experiments, and for studying changes in weight-average mass as a function of ligand concentration or mixing ratios of different proteins.

It should not be overlooked that sedimentation equilibrium experiments can be performed using preparative centrifuges, and this approach has advantages over the dedicated analytical instruments (Rivas and Minton, 1993). The collection of fractions at the end of the experiment allows any off-line method to be used to follow the concentration distribution, greatly extending the range of concentrations and specificity of detection methods. This also permits further separation of individual components by electrophoresis or chromatography prior to detection.

Sedimentation velocity experiments require only 2 to 5 hr, and thus can be employed for labile proteins, and are now often done at protein concentrations of 10 to 100 μg/ml instead of the 2 to 10 mg/ml common in the past. Stafford's *dc/dt* method of data analysis (Stafford, 1994) has been a boon to the field, and the stoichiometry of tight complexes can often be determined simply by observing the appearance of new peaks as reactants are mixed in various proportions (Stafford, 1997). Other recent developments in data analysis (Philo, 1994; Stafford, 1997; Schuck, 1998) now allow the simultaneous determination of diffusion coefficients along with the sedimentation coefficients, and thus calculation of the true mass, for nonassociating monomers as well as tightly associated oligomers or complexes, provided there is little dissociation during the experiment. In general, though, individual species or complexes are not resolved, and the data are analyzed to give an overall weight-average sedimentation coefficient that changes systematically as binding or self-association occurs. This latter approach is particularly useful for studying ligand binding when that binding is linked to protein self-association, as exemplified by recent work on drug binding to tubulin by Lobert and Correia (Lobert et al., 1998). The fitting of weight-average sedimentation data to obtain K_d can be complicated by the fact that the sedimentation coefficients depend on shape and conformation as well as mass, and thus it is generally not possible to accurately predict the sedimentation coefficients of oligomers or protein-protein complexes, and these must be treated as additional adjustable fitting parameters. On the other hand, the sensitivity to conformation can allow studying the binding of even very small ligands when that binding is linked to a conformational change. The latest development in using sedimentation velocity for studying interactions is use of finite-element numerical methods to directly simulate and fit a binding model (Schuck, 1998; Stafford, 1999). This approach can potentially obtain information about kinetics as well as K_d.

Titration Microcalorimetry

In titration microcalorimetry, interactions are detected through the heat that is released or absorbed as a binding event occurs. The fact that this heat of reaction signal is so universal, and does not require a significant change of mass or the presence of any chromophores, is one of the great strengths of this method. It is important to note that this method does not measure the true binding *stoichiometry* but rather measures only the *molar ratio* at which the reactants combine—i.e., it cannot distinguish a 1:1 from a 2:2 stoichiometry. This method can be applied to self-associating systems by detecting dissociation as the protein is diluted into buffer, but the limited concentration range, and lack of information about true stoichiometry, limit its utility in this area.

Titration calorimetry is often the method of choice for binding of low-molecular-weight ligands, particularly when the affinity is fairly low. Moreover, it is unique in directly giving information about the binding enthalpy, ΔH, in addition to measuring equilibrium constants and molar ratios. Another unique aspect of this technique is that the proton binding or release associated with a protein-protein or protein-ligand interaction can be quantitated simply by changing buffer systems (Doyle et al., 1995; Baker and Murphy, 1996).

On the other hand, phenomena other than the binding event of interest can sometimes generate significant amounts of heat, so titration calorimetry also has a unique set of arti-

BOSTON CENTRAL UNIVERSITY LIBRARY

facts that must be avoided. Among the potential problems are heat generated by small differences in pH or salt concentration between the titrant and the solution being titrated, and aggregation and precipitation of proteins induced by the stirring of the calorimeter cell. The heat due to solvent differences can of course be eliminated by thorough dialysis, but when studying binding of low-molecular-weight compounds, dialysis is often not possible. Limited solubility of the reactants can also create difficulties and force the use of large injection volumes, which generally compromises the signal/noise. Overall, though, this technique can be very useful, can give highly precise data, and the instrumentation and ease of use continues to improve.

Methods Based on Separation or Partitioning

The glamour and popularity of the some of the "high-tech," instrumentation-intensive methods should not overshadow a number of relatively simple and inexpensive approaches for studying protein interactions. For protein-ligand interactions, equilibrium dialysis or ultrafiltration often work well, and are still primary methods for studying drug binding to serum proteins (Sophianopoulos and Sophianopoulos, 1985; Sebille, 1990; Sebille et al., 1990). Gel filtration media can be used in either batch mode (Kido et al., 1985), for small-zone chromatographic analysis (Hummel-Dreyer analysis and its variants; Hummel and Dreyer, 1962; Andreu, 1985), or for large-zone (frontal) chromatography (Valdes and Ackers, 1979; Nenortas and Beckett, 1994). Virtually any method with good precision can be used to monitor the concentration of the protein or ligand following separation (or on-line monitoring may be used for chromatography), allowing great flexibility and an enormous concentration range. A common problem with these approaches is that the ligand or protein may bind to the membranes or resins. Furthermore, since transport is involved, one must be cautious about whether the measurements reflect equilibrium rather than kinetic properties. The material requirements may also be high unless some effort is devoted to keeping volumes small, and these approaches can be fairly labor intensive. Additional separation-based methods for protein-ligand interactions that have been used successfully are steady-state and counterion electrophoresis and isoelectric focusing (Oberfelder and Lee, 1985) and affinity-chromatography approaches (Winzor and De, 1989).

THE IMPORTANCE OF DATA ANALYSIS METHODS

Another common theme among these techniques is the central role of numerical methods for analysis and interpretation of the data, and this aspect has proven daunting for some researchers. Fortunately, today's desktop computers allow very sophisticated analyses to be done quickly and routinely, and the software has become increasingly user-friendly. Equally important, the data now are often acquired directly in digital form, and on-line computerized instrument control permits unattended operations and more complex data-acquisition protocols.

To see the tremendous impact the sum of all these phenomenon can have, one need look no further than at analytical ultracentrifugation. With new computerized instrumentation, formerly onerous data acquisition and analysis chores now take only seconds, and new numerical methods for analysis have added new capabilities and approaches. The net result is that a field that had all but disappeared has been rejuvenated.

In the area of data analysis, one frequently encounters the need to formulate specific models for use in analyzing the data. For example, protein self-association studies by large-zone SEC or sedimentation equilibrium are typically fitted to a specific assembly pathway such as monomer $\leftrightarrow$ dimer $\leftrightarrow$ tetramer. In such situations, it is always important to critically analyze whether the right model has been chosen, and to try to get independent information to support that choice of model. In this regard, information about the reaction stoichiometry (or at least the limiting assembly states) is often especially valuable.

Another important phenomenon in data analysis is the more widespread use of "global fitting" techniques. In global fitting, multiple experiments taken under different conditions (and possibly by different techniques) are analyzed simultaneously, using a common set of parameters to describe the molecular interactions. Such global analysis provides a much more robust analysis, and often allows more information to be extracted from a given set of experiments. This approach is fairly commonly used for certain techniques (e.g., analytical ultracentrifugation and SPR data), but is still seldom used for data from more than one type of instrument.

BCU IAS LIBRARY

SENSITIVITY TO CONTAMINANTS AND PROTEIN QUALITY

In general, the acquisition of accurate quantitative data on protein interactions will require highly purified, fully active protein samples, but a few of these techniques can be quite insensitive to the presence of contaminants or other proteins present as carriers. This is an area where the SPR sensors particularly excel, and titration calorimetry is also fairly insensitive to contaminants or carrier proteins.

Unfortunately, it is not uncommon for even highly purified protein samples to contain some inactive or partially active material, and further degradation may occur during the course of the measurements. This will usually limit the accuracy and reproducibility of the quantitative results, and possibly may even lead to false interpretations of the data. For example, proteins normally found as tightly associated oligomers often contain a small fraction of partially-denatured monomers that do not self-associate, or at least do so very weakly. Such species are often termed "incompetent monomers" in the analytical ultracentrifugation community. Suppose one is trying to quantitate the reversible dissociation of this oligomer at low concentrations in order to establish whether the oligomer exists at physiologically relevant concentrations. The presence of any incompetent monomer can result in a large increase in the *apparent* K_d for the dissociation when little reversible dissociation occurs over the experimentally accessible concentration range. Thus, extrapolation of such data to a low physiological concentration could lead to a false conclusion about the physiologically relevant quaternary structure.

Similarly, titration calorimetry is sometimes employed to study interactions with dissociation constants in the nanomolar range under conditions where the reactant concentrations are two to three orders of magnitude higher than the K_d. Under such conditions, it may be very difficult to distinguish a sample in which the majority of the protein binds extremely tightly (outside the range of the instrument) but a small portion of the protein binds more weakly, from one where 100% of the protein has a K_d that is close to the measurement limit of the instrument.

Such potential artifacts from inactive or partially active species can, of course, be detected through inconsistencies in the apparent K_d values for samples studied at different concentrations. That is precisely why it is often important to incorporate data from multiple experiments into the data analysis, and to cover as wide a portion of the binding isotherm as possible.

Overall, it is always advantageous to have highly pure, well-characterized, and stable protein samples. Before embarking on a detailed analysis of a complex set of protein interactions, it may be wise to devote some further effort to purification and to finding solvent conditions that promote stabilization. For proteins with poor stability, it will also be prudent to choose methods that are more rapid, and perhaps to work at lower temperatures.

THE ADVENT OF RECOMBINANT PROTEINS ENHANCES OUR CAPABILITIES FOR STUDYING PROTEIN INTERACTIONS

Biotechnology has had a profound influence on many areas of science and medicine, including the study of protein interactions. Many of the proteins being studied today are produced by recombinant technology, and would otherwise be unavailable in sufficient quantity (or totally unknown if they have been found through genomic or proteomic techniques). The quality of recombinant proteins (purity and homogeneity) can also often be superior to those from natural sources, in part because starting purification with larger amounts of protein allows more extensive purification protocols and more rigorous exclusion of side fractions.

Aside from issues of quality and quantity, a major virtue of recombinant proteins is the ability to engineer them in ways helpful for interaction studies. This is particularly useful for adding new, specific chemical groups such as cysteines for purposes of specifically immobilizing (e.g., SPR) or tagging the protein (e.g., fluorophores or isotopes). Such engineering may also involve adding new sequence motifs such as epitopes for commercially available antibodies or even entire functional domains such as green fluorescent protein.

Protein engineering can also be useful in enhancing certain physical properties of the protein. Among these are improving stability or solubility, removal of sites leading to heterogeneity (N-terminal processing, glycosylation), or even removing flexible loops. While some of these aspects may be more of interest in obtaining proteins better suited for high-resolution structural determination, lowering the chemical and structural heterogeneity may also be desirable before undertaking extensive interaction analysis of complex systems.

BOSTON UNIVERSITY LIBRARY

Last, but certainly not least, interaction studies done with site-directed mutants and/or proteins with deletions of individual functional domains allow a much more detailed interpretation of the interaction data and strongly enhance the analysis of structure/function relations.

THE VIRTUES OF USING MULTIPLE TECHNIQUES

Seldom can any one method give complete and fully reliable information about protein interactions. Each method has certain strengths and weaknesses, and may depend on certain models and assumptions. Therefore it is highly desirable, and sometimes necessary, to use multiple techniques in studying any protein interaction. Fortunately many of the techniques covered in this unit are highly complementary to one another, and this is definitely a field where the whole is greater than the sum of its parts.

It is always important to characterize the state of association of the protein(s) being studied. Such studies of self-association may be either the desired endpoint of an interaction analysis, or only preliminary to studying a protein-ligand interaction or the interactions between different proteins. Mass spectrometry provides, at the very least, an excellent beginning and foundation for other methods of studying self-association by verifying the covalent structure and determining an accurate monomer mass, and may also provide information about the presence of higher oligomers or binding of metal ions or other ligands (Anderegg et al., 1997).

Light scattering/SEC is also very useful (and very quick) for determining whether the predominant form is a monomer, dimer, or other oligomer. While this is not usually a good method for directly measuring the equilibrium constants for self-associating systems, it can be very helpful in identifying limiting stoichiometries, and may identify other assembly intermediates or the presence of incompetent monomer. Light scattering/SEC therefore can be an excellent prelude or adjunct to sedimentation equilibrium or large-zone analytical SEC (often the best methods for fully characterizing a self-associating system) by providing independent information about appropriate assembly models. In principle the combination of on-line scattering with large-zone SEC should make an excellent tool for measuring binding affinities of mixed- or self-associations, but this has not yet been extensively exploited, and the sensitivity of the scattering detectors may not be sufficient for studying stronger interactions ($K_d < 10^{-7}$ to 10^{-8} M).

A wide variety of methods can be applied to interactions between different proteins or protein-DNA interactions (so-called "mixed" or "heterogeneous" associations), and many are complementary rather than redundant. Once again a knowledge of stoichiometry can be very helpful in designing experiments and selecting proper models for data analysis, and mass spectrometry, light scattering/SEC, and chemical cross-linking can be very helpful in this regard.

In many cases, several techniques may be appropriate for determining the K_d, and if so it is certainly helpful to use more than one, particularly for complex associations or when the information is critical. One field where there has been a particularly nice synergy between methods such as sedimentation equilibrium, SPR, light scattering/SEC, and titration calorimetry has been in studies of interactions between protein hormones and their receptors (Ward et al., 1994; Zhang et al., 1997; Philo and Hensley, 1998). By confining receptors to the surface of SPR sensors it has also been possible to more closely mimic the situation when the receptor is embedded in the cell membrane, and even multisubunit receptor complexes have been assembled on the sensor surface (Kalinin et al., 1995; Myszka et al., 1996). Comparison of such data with those from solution methods such as sedimentation equilibrium or titration calorimetry may allow a more thorough understanding of the importance of having the hormone interact simultaneously with multiple receptor subunits, and determination of the energetic consequences of having the receptors preoriented in a fashion enabling such interactions.

SOME THOUGHTS ON CHOOSING METHODS

As mentioned earlier, the fact that most of the methods are based on changes in mass often limits their application to studying binding of low-molecular-weight compounds, so for such materials, titration calorimetry or a "low-tech" approach like equilibrium dialysis may be particularly advantageous. For protein-protein or protein-DNA interaction studies, the choice of method(s) for determining the K_d will often be dictated by the magnitude of that K_d. Both titration calorimetry and sedimentation equilibrium lack the sensitivity to measure K_d values below ~10^{-8} to 10^{-9} M. Stronger interactions with K_d values down to ~10^{-12} M can be studied by SPR or fluorescence techniques. By

BCU IAS / CENTRAL UNIVERSITY LIBRARY

coupling them to highly sensitive radiometric, fluorometric, or ELISA assays, techniques such as equilibrium dialysis, ultrafiltration, micropreparative analytical ultracentrifugation, or large-zone analytical SEC can also study K_d values in the picomolar range or lower. At the other extreme, weak interactions with K_d values up to ~10^{-3} M can be measured by analytical ultracentrifugation, titration calorimetry, SPR, equilibrium dialysis, or ultrafiltration. With very weak interactions, reactant solubility may limit the application of titration calorimetry, while nonspecific binding to the surfaces can be problematic for SPR, dialysis, and ultrafiltration.

In other cases the choice of technique to apply to obtain the K_d of a mixed or self-association may be dictated by the amount of material that is available. For the less sensitive techniques such as sedimentation equilibrium and titration calorimetry, where this is most likely to be an issue, as a rule of thumb the minimum amount of protein needed to run one sample with good signal/noise ratio is ~10 µg for sedimentation equilibrium (with a 3-mm column), and ~100 µg for titration calorimetry. However, the amount of material needed is often dictated not by the inherent detection limits of a particular instrument, but rather by the necessity to run at least one sample at a high enough concentration to promote essentially full association (i.e., 10 times the K_d or preferably higher). Thus, the material requirement is often proportional to the product of the K_d and the minimum volume needed for this high-concentration sample. For the more sensitive methods, this volume requirement may actually be dictated more by sample-handling considerations than by how much material actually enters the instrument. For sedimentation equilibrium, the minimum volume is ~100 µl, for sedimentation velocity ~400 µl, and for titration calorimetry ~2 ml. In SPR the material requirements for the reactant that will be coupled to the sensor surface is quite small; material requirements are usually only a potential concern for the reactant in solution. For flow-based SPR sensors the minimum volume for the solution reactant depends on flow rate and injection length, which in turn vary with the kinetics of the process and whether the instrument is operated in a kinetic or equilibrium-binding mode, but this volume is typically ~100 µl. In large-zone SEC, the volume required depends on the column volume but is often several milliliters (or more).

OBTAINING ADDITIONAL THERMODYNAMIC INFORMATION

Additional insight into protein interactions can be obtained by extracting solution thermodynamic quantities from the experimental data. As mentioned previously, titration calorimetry measures the binding enthalpy, ΔH, directly (and this quantity can be measured easily even when the K_d is too low to be measured). When the K_d is also known, the entropy change can then be calculated from the relation $\Delta G = RT\ln(K_d) = \Delta H - T\Delta S$. The magnitudes of ΔH and ΔS may provide some insight into the nature of the interaction (e.g., whether it is predominantly hydrophobic or electrostatic). However these net quantities are sums of contributions from many effects, and are often dominated by interactions with the solvent, so structural interpretation is risky at best.

A more promising approach to structural interpretation of the thermodynamic data comes from examining the change in heat capacity, Δc_p. This can be obtained by measuring the calorimetric ΔH at several temperatures and taking the slope of a plot of ΔH versus T, through the relation $\Delta c_p = \delta(\Delta H)/\delta T$. This Δc_p can then be interpreted in structural terms, as either a change in buried surface area when the complex is formed (Murphy and Freire, 1992) or as the number of amino acid residues that go from a disordered to an ordered state as a consequence of the interaction (Spolar and Record, 1994).

The apparent, or van't Hoff, enthalpy change, ΔH_{vH}, can also be obtained by measuring the K_d as a function of temperature (using any method) if it is assumed that ΔH and ΔS are constant with temperature (at least over some narrow range). This is done by plotting $\ln(K_d)$ versus $1/T$ (a van't Hoff plot), taking the slope of a line through the data, and using the relation $\Delta H_{vH} = R\delta(1nK_d)/\delta(1/T)$. The calorimetric and van't Hoff enthalpies may differ significantly. The calorimetric ΔH includes *all* heats associated with the overall biochemical reaction, whereas ΔH_{vH} includes only those reactions that directly influence the K_d, and thus may not include heats associated with solvation, ionization, or conformational changes if those processes have no net effect on the binding free energy (Bundle and Sigurskjold, 1994).

It is also possible to take advantage of the temperature dependence of equilibrium constants to extend the range of affinities that can be covered by any given method. Since most reactions are exothermic (negative ΔH), they

B.C.U. „M. EMINESCU" IAŞI
CHIMIE

BOUWINGER CENTRAL UNIVERSITY LIBRARY

become weaker as the temperature is increased. Thus for studying very strong affinities it may be helpful to determine the K_d at high temperature and then correct this value to lower temperature using measured values for ΔH (and preferably Δc_p also). This approach has been used, for example, to study high-affinity antigen-antibody binding (Schwarz et al., 1995).

THERMODYNAMIC LINKAGE RELATIONSHIPS

The concept of thermodynamic linkage has provided a powerful tool for probing and understanding protein interactions, and also serves as a basis for extending the range of affinities that can be probed. Consider first a protein, P, that can bind a ligand, L, and that also self-associates to form dimer. The ligand binding and association reactions form the thermodynamic cycle, illustrated in Figure 20.1.1. Because the total change in free energy must be independent of the pathway, if the dimer binds ligand with a different affinity than the monomer, it must also be true that the liganded form dimerizes differently than the unliganded form, such that $\Delta G_L - \Delta G_L{}^d = \Delta G_d{}^L - \Delta G_d$ (or equivalently $K_L/K_L{}^d = K_d{}^L/K_d$).

How does this exercise help us? Suppose the dimer binds ligand more strongly than monomer, so strongly that we cannot measure the affinity. This linkage relationship says that if we can determine the (lower) affinity of the monomer, we need only measure the monomer-dimer dissociation equilibrium of the unliganded and liganded forms, and we may then calculate the ligand affinity of the dimer. This very simple but powerful idea has been exploited with tremendous success, for example, by Gary Ackers and his co-workers in detailed studies of oxygen binding and subunit assembly for hemoglobin (Turner et al., 1981; Ackers, 1998), in probing protein-DNA interactions (Koblan and Ackers, 1991), and in many other systems.

These same linkage concepts can also be applied when the protein's affinity for a ligand varies with pH, ions such as calcium, or effectors such as nucleotide phosphates, rather than through self-assembly. For example, since titration calorimetry can fairly easily quantitate proton uptake and release, a reaction whose affinity is too high to be studied at neutral pH can be studied at a pH where the binding is weaker, and then corrected to neutral pH conditions using the linkage relations and the difference in proton binding (Doyle et al., 1995; Baker and Murphy, 1996).

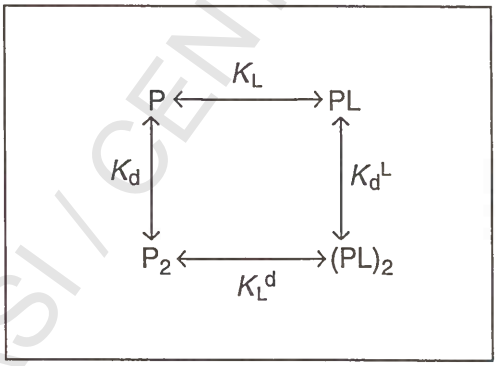

Figure 20.1.1 Thermodynamic cycle for ligand binding and association reactions. K_L and $K_L{}^d$ are the association constants for ligand binding for the monomer and dimer, respectively, and K_d and $K_d{}^L$ are the monomer-dimer association constants for the unliganded and liganded form of the protein, with corresponding free energies ΔG_L, $\Delta G_L{}^d$, ΔG_d, and $\Delta G_d{}^L$.

Measuring Protein Interactions by Optical Biosensors

Optical evanescent wave biosensors, such as surface plasmon resonance, resonant mirror, or waveguide biosensors, have been increasingly used during the last several years for the characterization of protein-protein interactions (Schuck, 1997a; Margulies et al., 1993, 1996; van der Merwe and Barclay, 1996; Malmborg and Borrebaeck, 1995; Garland, 1996). This includes both the determination of equilibrium binding constants, which reveal the magnitude of the binding energy, as well as the determination of the bimolecular rate constants describing the kinetics of the interaction.

Studying protein interactions at a surface, as opposed to solution methods, has at least two fundamental advantages. First, the magnitude of the signal involved is independent of the affinity of the interaction over a wide range. Because one binding partner is confined to the surface (in the following referred to as ligand), the number of free binding sites that are under observation in an experiment is determined predominantly by the surface immobilization procedure (requiring usually only very small amounts of material). Therefore, the sensitivity of the method is limited essentially by the availability of the soluble binding partner (the analyte) in a well-defined state, at concentrations in the order of the inverse affinity constant. This allows studies of interactions with affinities spanning a range of at least 10^5 to 10^{10} M^{-1}, and makes this method very attractive, in particular, for high-affinity interactions. Second, the separation of the surface-immobilized sites from the mobile binding partners in solution, if combined with an appropriate fluidic handling system, is virtually ideally suited for the real-time observation of the kinetics of the binding processes. Chemical on-rate constants of up to 10^5/Msec to 10^6/Msec and off-rate constants of between 10^{-5}/sec and 10^{-1}/sec are generally accessible. Information on the chemical on-rate constants, and on the lifetime of the complexes formed, can be of great value, for example, in the study of interactions involved in cellular signaling processes.

However, these fundamental advantages are gained at the expense of additional experimental difficulties intrinsic to surface binding studies. These include the need for immobilization of one reactant at a relatively high local surface density (and the execution of binding studies under these conditions), the problems of nonspecific surface binding, possible multiple attachments to the surface through multivalent interactions, the problem of mass transport in kinetic experiments, and finally the possibility of surface potentials influencing the thermodynamics of the interaction (Leckband, 1997; Leckband et al., 1995).

Although the different commercial instruments for optical biosensing are based on slightly different physical principles, they all exploit surface-confined electromagnetic fields for the precise and real-time measurement of the refractive index of the medium in the immediate vicinity of the sensor surface (Garland, 1996; Knoll, 1998; Lukosz, 1991). When ligands are immobilized to the sensor surface, reversibly interacting analytes will accumulate at the sensor surface when brought into the solution above. By virtue of the difference of the refractive index increments of proteins and most aqueous buffer solutions, an increase of the total refractive index at the surface will then be reported (Fig. 20.2.1). Removal of the analyte from the solution causes dissociation of the reversibly bound molecules from the surface sites, which is accompanied by a decrease in the refractive index at the sensor surface, generating a decrease in the signal. Since the changes in signal are, to a good approximation, proportional to the changes in the mass of surface-bound analyte, the steady-state signals can be analyzed in terms of the law of

mass action and Langmuir isotherms. The time course of the signal can be interpreted in the context of chemical binding kinetics. This basic principle, and consequently the derived strategies for studying protein-protein interactions, as well as most of the experimental procedures and potential complications, are the same in the different commercial instruments. Among the manufacturers are Biacore (*http://www.biacore.com*), Affinity Sensors (*http://www.affinity-sensors.com*), Intersens Instruments (Amersfoort, Netherlands), BioTul (*http://www.biotul.com*), and Artificial Sensing In-

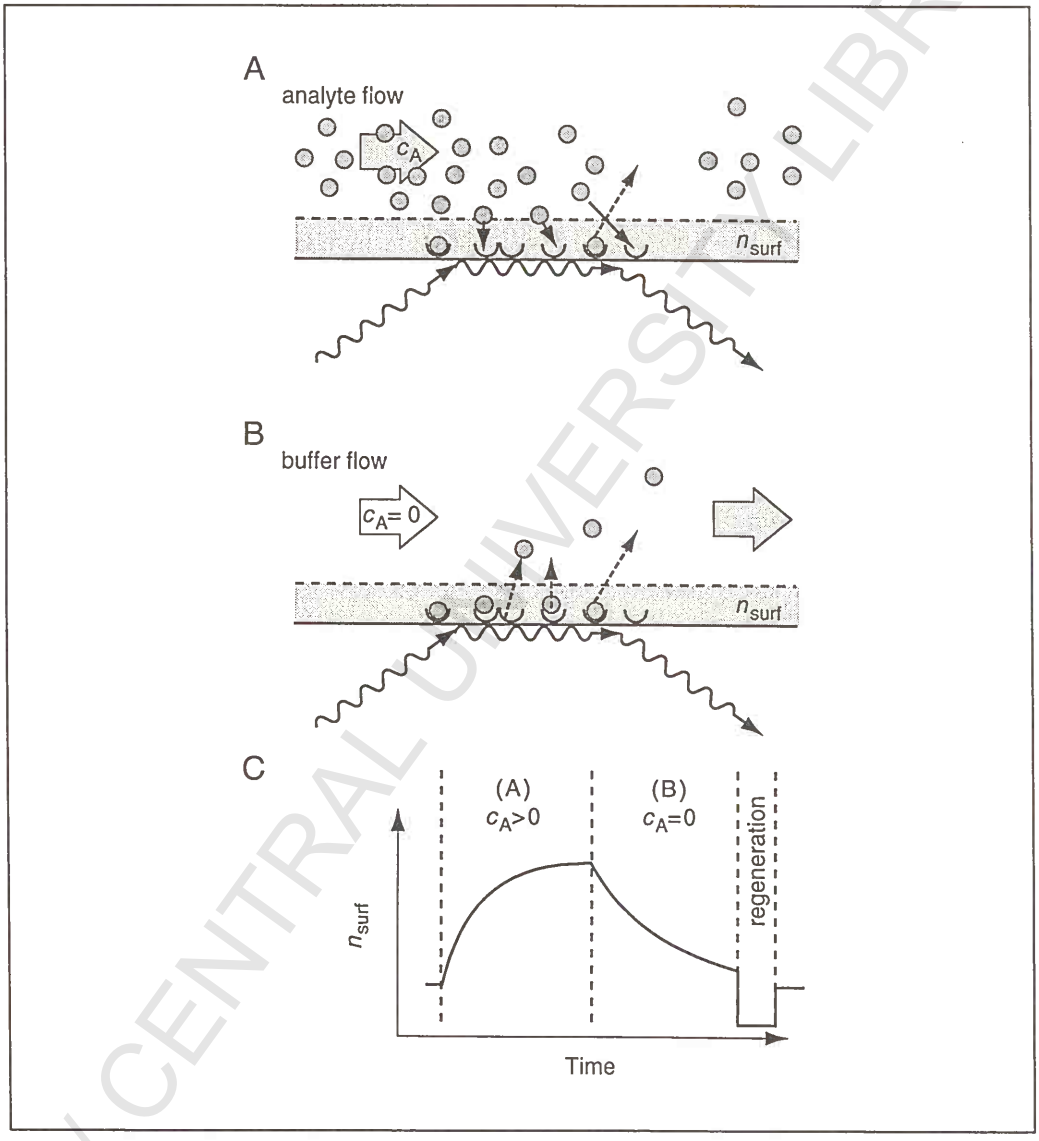

Figure 20.2.1 Schematic presentation of a typical optical biosensor experiment. Light is coupled into a structure that allows generation of surface-confined electromagnetic waves (e.g., surface plasmons in a gold film, or modes of a planar waveguide), which are sensitive to the refractive index of the solution in the range of the evanescent field, n_{surf}. Typical penetration depths of the sensitive volume into the solution are in the order of 100 nm. Ligands are attached to the sensor surface, as indicated by half-circles. (**A**) When analytes (full circles) are introduced into the solution above the surface, reversible interactions with the ligand lead to association events at a rate governed by $k_{on}c_Ac_{L,free}$ (solid arrows), and dissociation events at a rate $c_{complex}k_{off}$ (dashed arrows). In the association phase, association events outnumber dissociation events until a steady state is reached. (**B**) When the surface is washed with running buffer in the absence of analyte, only dissociation events take place. (**C**) Signal obtained from probing the refractive index n_{surf} during the sequential application of the configurations depicted in A and B, given in arbitrary units. Following the association phase (A) and the dissociation phase (B), usually a regeneration procedure is applied for removing all remaining analyte from the surface before a new experimental cycle takes place.

RCU IASI CENTRAL UNIVERSITY LIBRARY

struments (ASI AG, Zürich, Switzerland). The purpose of this unit is to provide a brief introduction to these techniques for the quantitative characterization of biomolecular interactions.

At the time of the introduction of optical biosensors in biomedical research, these instruments were thought to offer a particularly simple technique for the rapid quantitative measurement of equilibrium binding constants as well as binding kinetics. The reader is cautioned that the apparent simplicity and rapidity of the method is deceptive, and that the ease of using some of the commercial data analysis software packages can be highly misleading. The reliability of many of the initially used approaches in this field could not be verified in subsequent critical assessments of the methods. However, the technique has evolved significantly during the last few years. This is mainly due to the refinement and increasing variety of immobilization strategies, the identification of sources of artifacts, the use of control experiments, and the maturation of the analytical techniques (most notably global modeling). Emphasis is given in this unit to introducing the reader to robust approaches that will result in reliable results. Although the technique is frequently presented as being label-free, one of the interacting proteins has to be attached in an active form to the sensor surface. Most frequently, this is accomplished through covalent coupling, which can introduce all the problems well-known in chromophoric labeling and related covalent protein modifications. For all these reasons, the use of this technique requires careful planning and the execution of a number of different experiments, with time and effort more or less comparable to any of the other techniques available for the study of protein-protein interactions.

Optical biosensors are very versatile for the study of protein interactions. However, as described below (see Strategic Planning), the choice of the experimental strategy is usually dictated by the proteins under investigation. Only general guidelines can be given for this stage of the experiment. Detailed procedures for some of the most commonly employed immobilization procedures are described, followed by an introduction to the different strategies for the binding studies, and a brief description of some of the most commonly encountered problems. Next, the need for control experiments is emphasized, and the execution of a variety of such control experiments is described. Finally, some ideas are given for simple troubleshooting. Obviously, this introductory unit cannot be even remotely complete, or cover many of the more advanced techniques such as assembly of protein complexes (Andersen et al., 1999; Schuster et al., 1993). For many of these, the reader will be referred to the specialized literature cited throughout this unit.

STRATEGIC PLANNING

The first step in planning a biosensor experiment for the measurement of the interaction of two proteins requires the choice of the binding partner to be immobilized and the type of binding experiment that will be employed (steady-state, kinetic, or competition experiment, see Binding Experiments and Data Analysis). This involves the consideration of several factors related to size, purity, and chemical properties of the protein, as well as the stoichiometry of the interaction. In general, this will require the protein samples to be well characterized with respect to these properties.

Size, Concentration, and Volume

Optical biosensors detect changes in the refractive index at the sensor surface due to analyte binding. This signal is superimposed by an offset from the bulk refractive index differences of the buffers used). Because the refractive index increment of proteins is very similar in units of weight concentration, the signal obtained from saturation of a given

BOJIAN CENTRAL UNIVERSITY LIBRARY

number of surface sites will increase with increasing molar mass of the soluble protein (or other analyte). In some of the commercial instruments, the binding of an analyte with a molar mass of only 1000 Da can be detected without difficulty, given the commonly achievable surface densities of sites. There is virtually no upper limit for the size of the analyte. Size consideration is important before setting up the experiment if the two binding partners to be studied are of significantly different size. The choice of a larger species as the analyte is generally preferable because this provides a larger signal. However, the immobilization of a very small peptide is usually difficult to control, and in practice frequently leads to unsuitably high density of surface sites, which can introduce problems of steric hindrance and mass transport limitation (see discussion of Mass Transport Limitation). In the absence of any other considerations, it seems advantageous to immobilize the larger binding partner, in order to diminish the probability of steric hindrance problems brought about by binding to surface sites in close vicinity. This will also help to minimize the probability of the immobilization affecting the conformation of the binding epitope. On the other hand, peptide ligands often are far more resistant to the denaturing effects of repeated cycles of binding and regeneration, and can be expected to provide a more stable binding surface than most proteins.

If one of the proteins under study is available only in small quantities, it is advantageous to immobilize this species, because during the course of a study usually only a few functionalized surfaces are needed, each requiring usually only a few micrograms of material. The analytes are used in larger amounts; in one complete set of kinetic experiments volumes of the order of 100 µl at concentrations of ten times the K_D are typically required. In competition experiments, similar quantities of the immobilized species are additionally required. The active concentration of the analyte should be well known, because errors in this value will directly translate into proportional errors of both the binding constant K_D and the chemical on-rate constant k_{on}, resulting from analysis of the experiment (see Binding Experiments and Data Analysis).

Purity

The sample purity requirements in biosensor experiments can be relatively low. In principle, the criterion for sufficient purity is the absence of cross-reaction between the two samples, aside from the interaction of the proteins under study—i.e., that no binding occurs between any contaminating species in the ligand sample and in the analyte sample. In practice, this means that at least either one of the samples should be highly purified. However, very strict requirements have to be met to ensure the absence of contaminating multimeric aggregates of the mobile species (see discussion of Analyte Aggregates, below, and Davis et al., 1998).

Oligomeric Structure, Stoichiometry, and Multivalent Binding

It is important to avoid multiple attachment of a single analyte molecule to two or more surface sites. If this occurs, the lifetime of the surface-bound complex is greatly enhanced. This avidity effect depends strongly on the local density of surface sites (Muller et al., 1998), and the binding data obtained under these conditions are governed to a large extent by the specific properties of the functionalized surface, much more than the surface binding properties of the analyte. (It cannot be assumed that the avidity effect of multivalent binding to the sensor surface is similar to possible avidity effects in binding to cell surface receptors.) Therefore, if the proteins under study are subject to multimeric binding, the multivalent species must be chosen for immobilization. For example, in antibody-antigen interactions, the antibody should be immobilized and the antigen should be the mobile analyte (Fig. 20.2.2). For unknown stoichiometries, appropriate control experiments should be performed that can identify the presence of multivalent species.

BCU IASI CENTRAL UNIVERSITY LIBRARY

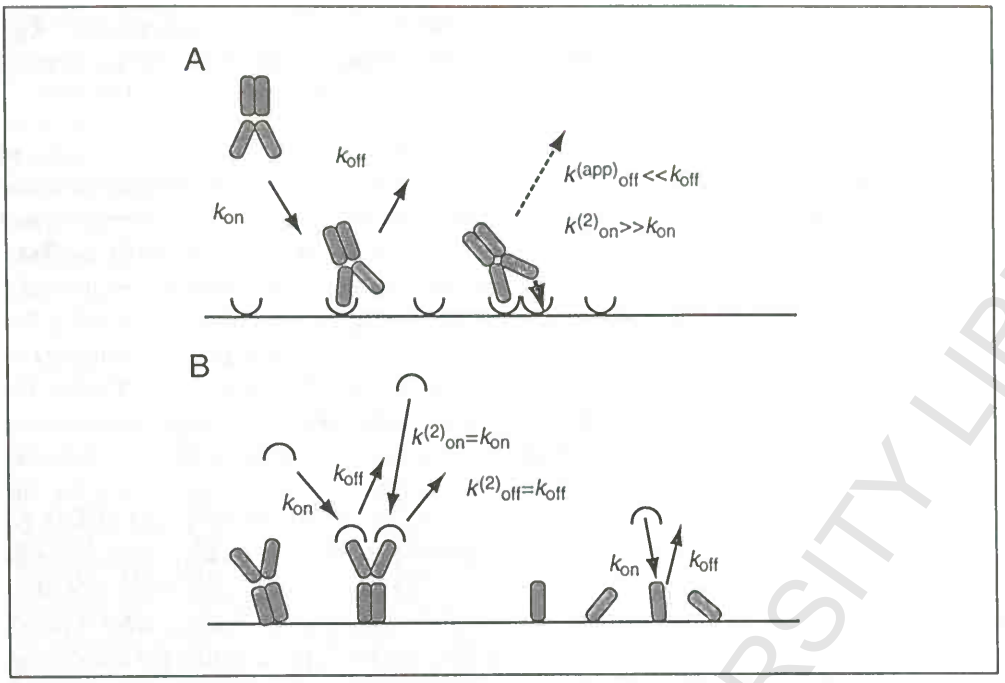

Figure 20.2.2 (**A**) The binding of a bivalent analyte can take place through the interaction with a single ligand molecule (left), or with two ligand molecules (right), depending on the local ligand density. If an unoccupied immobilized ligand molecule is within an accessible distance to an already singly bound analyte molecule, then the on-rate constant of the second interaction is strongly enhanced because of the entropic colocalization constraints. The overall dissociation rate constant of the double attached analyte is substantially reduceed (usually by orders of magnitude), because it requires the virtually simultaneous dissociation of both interactions, which is much more improbable than a single dissociation event. The overall binding kinetics obtained from multivalent analytes is highly complex. (**B**) If the configuration is reversed, with the bivalent binding partner immobilized to the sensor surface, then both valencies act independently (left), and (in the absence of cooperativity of the sites) lead to binding kinetics that are identical to that of the monovalent interactions (right).

For the same reason, the presence of even very small amounts of reversibly formed oligomers (self-association) or irreversibly formed oligomers can significantly interfere with the analysis of surface binding equilibria or kinetics. Because of the difficulties in detecting relatively weak or rapidly reversible oligomerization, solution techniques like analytical ultracentrifugation can be preferable to chromatographic or electrophoretic techniques.

Reactive Properties: Susceptibility to Immobilization, Nonspecific Binding, and Regeneration

The key to successful biosensor experiments is the immobilization of one protein species in an active, and, if possible, uniformly oriented state to the sensor surface. The ease of immobilization can be the major consideration for the choice of the immobilized species. Examples are the presence of biotin, histidine, or other tags on the molecule that allow specific capture, or the presence of a single accessible cysteine suitable for employing specific cross-linking chemistry. If a protein is produced by recombinant methods, appropriate tags can frequently be introduced.

Analogously, the protein that exhibits less nonspecific surface binding is the preferable choice for an analyte. Many sensor surfaces are slightly hydrophobic, and it is highly recommended to measure the extent of binding of both proteins to the nonfunctionalized surface at the maximal concentrations to be used in the binding experiments (e.g., at

BOSTON CENTRAL UNIVERSITY LIBRARY

concentrations equal to 10-fold the expected dissociation equilibrium constant, K_D). Significant degrees of nonspecific binding can make the analysis of the surface binding kinetics very difficult.

Most analytical strategies require a series of multiple association/dissociation cycles to be executed with the same surface. Therefore, conditions need to be established that allow removal of all surface-bound analyte, without permanently altering the conformation and activity of the immobilized ligand (but tolerating possible destruction of the analyte). Naturally, the choice of the regeneration procedure depends very much on the proteins. Frequently, helpful hints can be obtained from the procedure used to purify the ligand—e.g., conditions employed during ion-exchange or affinity chromatography. Examples of common regeneration procedures include exposure to low-pH glycine or HCl buffer for 1 or 2 min. For some sensitive ligands that interact weakly with their respective analytes, an extended washout with the binding buffer is the gentlest and most reliable regeneration procedure. After selection of a regeneration procedure, control experiments for the integrity of the surface and for the reproducibility of the observed signal should be performed. These should consist of several identical association/dissociation/regeneration cycles. Insufficient regeneration can be identified by residual signal increase after each cycle and/or a negative drift of the baseline. The loss of binding sites through too-harsh regeneration conditions is indicated by a maximal signal during the association phase, which decreases with each cycle. Regeneration is not required for the equilibrium-titration techniques (Schuck et al., 1998; Myszka et al., 1998).

IMMOBILIZATION PROTOCOLS

The goal of immobilization is the stable coupling of the ligand to the sensor surface in an active form. In addition to the obvious functional test of analyte binding during the course of the interaction study, probing the conformation with monoclonal antibodies against ligand epitopes can be highly useful. If possible, it is desirable to reverse the role of ligand and analyte to rule out artifacts of immobilization on the interaction. It is important to note that the immobilization methods differ in their requirement for the exposure of the ligand to relatively harsh conditions, such as pH values below the pI in the commonly employed amine coupling. A related consideration in the choice of the immobilization strategy is the orientation of the surface-immobilized ligand. Random coupling techniques, such as amine coupling, may create different subpopulations of differently reactive ligand molecules at the surface, while specific orientation techniques (e.g., through specific cysteines or through specifically attached biotin moieties) create uniform surfaces. An elegant method for allowing uniform surface attachment is the introduction of specific tags (such as cysteine or histidine) into recombinantly produced or synthetic ligands.

Below are basic descriptions of three of the most commonly used immobilization techniques, which can be applied to the most commonly employed carboxymethylated dextran sensor surfaces. In any of these methods it is very important to control the number of surface sites, since several surface-related artifacts are invoked if the surface density of the proteins under study is too high. The density of immobilized protein can be measured as the difference of the signal before and after immobilization, which can be transformed into the maximal analyte binding capacity by multiplication with the molar mass ratio of the analyte and ligand. For kinetic experiments, generally a relatively low density of immobilized protein should be obtained—i.e., a binding capacity of 50- to 200-fold of the instrumental noise [~50 to 200 units (RU) on a Biacore system]. For competition and for certain control experiments (see Competition Analysis), a larger binding capacity can be desirable. In practice, for initial orientation on the behavior of a particular system of interacting proteins, it is best to prepare several different surfaces of

RCU IAS | CENTRAL UNIVERSITY LIBRARY

different ligand densities and to compare the analysis of each. This will be helpful for diagnosing the regimes where mass transport limitations may be present (see Mass Transport Limitations), or where high surface coverage may lead to steric hindrance of analyte binding to neighboring surface sites (leading to biphasic surface binding kinetics).

Instruments that allow the on-line observation of a reference surface can be optimally utilized if the reference surface is treated as similarly as possible to the functionalized surface. This is important predominantly because of possible nonspecific interactions of the analyte with the sensor surface, and the possible changes in surface properties due to immobilization. For amine coupling, this can include the application of the activation/deactivation cycle to the reference surface, but without cross-linking of any protein, or with cross-linking of a nonfunctional control protein (for example an unrelated antibody of the same isotype). For the same reason, if using biotin-streptavidin coupling, it is advantageous to immobilize streptavidin to both surfaces.

A variety of additional immobilization techniques are available in addition those described below, such as hydrazide coupling (O'Shannessy et al., 1992), Ni^{2+} chelate coupling (Gershon and Khilko, 1995; O'Shannessy et al., 1995; Sigal et al., 1996), coupling of hydrophobic groups (Stein and Gerisch, 1996), the use of self-assembled monolayers (Sigal et al., 1996) or supported lipid or hybrid bilayers (Plant et al., 1995; Ramsden et al., 1996), and immobilization to aminosilane-derivatized surfaces (Edwards et al., 1995; Buckle et al., 1993). For details on chemical modifications of the proteins, see Hermanson (1996). Additionally, capturing strategies can be used for reversible attachment of the ligand. More specific information on commercially available sensor surfaces, and step-by-step protocols for the corresponding immobilization techniques, can be found in the commercial instrument handbooks, such as the Biacore applications handbook or the IAsys applications notes.

Amine Coupling

Amine coupling is most frequently carried out using a sensor surface that is modified with carboxymethylated dextran. It relies on the electrostatic preconcentration of the ligand to the sensor surface, and therefore requires that the proteins be positively charged. The coupling buffer should be 1 to 2 pH units below the pI of the protein, of low ionic strength (to avoid charge screening), and not contain any primary amines. Effective pre-concentration can be tested before the activation of the surface. It is frequently necessary to test immobilization with several different buffers of slightly different pH; an adjustment by only one half pH unit can be crucial for a successful immobilization.

In a typical protocol, the carboxyl groups of the sensor surface are activated by exposure for 5 to 7 min with 50 mM *N*-hydroxysuccinimide (NHS) and 200 mM *N*-ethyl-*N'*-(dimethylaminopropyl)carbodiimide (EDC). Next, the ligand is injected in 10 mM sodium acetate pH 4.5 buffer. To control the amount of cross-linked ligand, it is usually better to adjust the reaction time as compared to adjustment of the ligand concentration. Repeated injection/wash cycles can be used to differentiate the covalently attached ligand from electrostatically surface-bound ligand. Finally, the surface is deactivated with 1 M ethanolamine·HCl, pH 8.5, for 7 min. Biacore and IAsys provide kits and prepared buffers for this procedure. The NHS and EDC should be kept frozen separately, in aliquots, at –20°C until use.

Avidin- or Streptavidin-Biotin Coupling

Covalent immobilization of avidin or streptavidin allows the capture of biotinylated proteins. This method avoids the need to expose the protein to a pH lower than the pI, and therefore can better preserve activity. Procedures for biotinylating the analyte are found

BOULDER CAMPUS LIBRARY UNIVERSITY OF COLORADO

in Hermanson (1996). The affinity of biotin-avidin interaction is very high and leads to a very stable surface. It should be noted that streptavidin-coated surfaces tend to be more sticky and lead to an increased level of nonspecific binding of the analyte to the surface. Therefore, good blank control surfaces are important.

The amine coupling protocol described above and a carboxymethylated dextran surface can be used for this procedure. The surface is activated with NHS/EDC (see discussion of Amine Coupling), the streptavidin (~100 μg/ml in buffer of pH 4.5 to 5.0) or avidin (~50 μg/ml in pH 4.5 buffer) is immobilized, and the surface is deactivated with ethanolamine. Note that, if commercially prepared streptavidin surfaces are used, this activation step can be omitted. The biotinylated protein is then injected; usually concentrations of 10 to 100 μg/ml and low flow rates are sufficient for efficient capture. Typical times for exposure of the surface are 10 to 30 min.

Thiol-Disulfide Exchange Coupling

This immobilization technique is frequently used for acidic proteins, for small peptides, and for cases when immobilization in a specific orientation is important. It also serves as a highly efficient coupling procedure that can be used if amine coupling or avidin-biotin coupling is unsuccessful. In this method, the immobilization is accomplished either by the introduction of an active disulfide group onto the sensor surface, which can react with thiols on the protein to be immobilized, or, vice versa, by the modification of the sensor surface with a thiol group, which then can react with active disulfides on the protein. The choice between these alternative procedures is dependent on the protein, i.e., the presence of accessible thiol groups, or the potential for introducing activated disulfide groups. The latter procedure may be accomplished, e.g., using 2-(2-pyridinyldithio)ethaneamine (PDEA) to derivatize carboxyl groups or succinimidyloxycarbonyl-α-methyl-α-(2-pyridyldithio)toluene (SMPT) for derivatizing amino groups. It should be noted that, in general, thiol-disulfide exchange coupling cannot be used for studies in the presence of reducing agents. However, the use of covalent thioester coupling—e.g., with succinimidyl 4-(*N*-maleimidomethyl) cyclohexane-1-carboxylate (SMCC), sulfo-SMCC, or *N*-(γ-maleimidobutyryloxy)succinimide ester (GMBS)—produces a surface that is stable against reducing agents, and allows one to specifically chose the site of coupling. In addition, the latter technique provides a small spacer between the protein and the surface, which may allow better accessibility (Khilko et al., 1995).

BINDING EXPERIMENTS AND DATA ANALYSIS

Optical biosensors provide data on the time course of analyte binding, and allow for a number of different experimental and analytical strategies for interaction analysis. Most rely on a repeated cycle of association, dissociation, and surface regeneration (Fig. 20.2.1). Among the most important analysis strategies are the kinetic analysis, which takes advantage of the real-time observation to obtain the kinetic rate constants of the reaction; the steady state analysis for measuring the affinity of the reaction; and the competition analysis for measuring the affinity of the interaction in solution. The choice may be constrained by the affinity and kinetics of the proteins under study. If possible, multiple approaches should be taken and the results should be compared for their consistency. Their optimal application requires approximate knowledge of the order of magnitude of the affinity of the interaction. This may make it necessary to perform these studies in several steps.

BCU IASI - CENTRAL UNIVERSITY LIBRARY

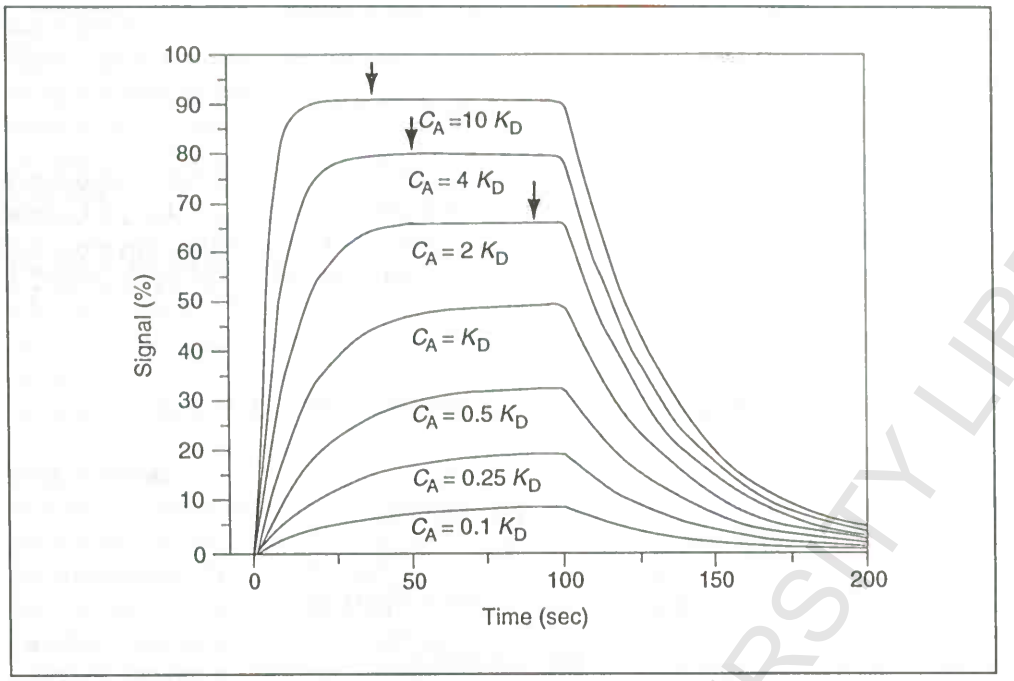

Figure 20.2.3 Schematic presentation of an ideal 1:1 pseudo first-order reaction. Shown is a superposition of the binding progress curves that should be obtained in a series of experiments at different analyte concentrations. The data are given in percent of the signal at maximal binding, but the units of the signal do not affect the results of the data analysis. The arrows on the curves at the higher concentrations indicate that steady-state binding is attained, whereas, for the lower curves, longer association times would be required as part of a steady-state analysis.

CHI...IE

Kinetic Analysis

Experimental

The experiment consists of repeated injections of the analyte at different concentrations (Fig. 20.2.3). It should be conducted at relatively low surface density of sites, to avoid kinetic artifacts arising from mass transport limitation. An analyte concentration range as wide as possible should be covered (at least from 1/10 of the K_D to 10 times the K_D), using two-fold or three-fold dilutions. The time allowed for the surface binding phase (injection time) should be long enough for the observation of significant curvature in the binding progress, since it is only the curvature that contains the information about the reaction rate constants. It is highly desirable that steady-state binding be attained, at least for the highest concentrations used. The observation time for the dissociation phase should at least be similar to the injection time.

Data analysis

If the analyte-ligand interaction follows a pseudo first-order reaction, L + A ⇔ LA then the measured binding progress (proportional to [LA]) is described by:

$$\frac{dR}{dt} = k_{on} c_A (R_{max} - R) - k_{off} R$$

Equation 20.2.1

where c_A denotes the analyte concentration, R denotes the signal (in arbitrary units), and R_{max} denotes the signal at maximum saturation of the surface sites. The goal is the calculation of the chemical on-rate and off-rate constants, k_{on} and k_{off}, which relate to the equilibrium constant as:

BCU IASI / CENTRAL UNIVERSITY LIBRARY

$$K_D = \frac{k_{off}}{k_{on}}$$

Equation 20.2.2

While it is possible, in principle, to transform the data as dR/dt versus R in the association phase and as log(R) versus time in the dissociation phase, where $k_{obs} = (k_{on}c_A + k_{off})$ and k_{off}, respectively, would represent the slopes of the obtained straight lines, this procedure is very unreliable. Instead, it is state-of-the-art procedure to directly fit Equation 20.2.1, or its integrated form:

$$R_{assoc}(t) = \frac{R_{max}}{1 + \frac{k_{off}}{k_{on}c_A}}[1 - \exp(k_{on}c_A + k_{off})t]$$

Equation 20.2.3

$$R_{dissoc}(t) = R_{assoc}(t_d)\exp[-k_{off}(t - t_d)]$$

Equation 20.2.4

directly to the data (with t_d denoting the end of the association and the beginning of the dissociation phase, where $c_A = 0$; O'Shannessy et al., 1993). This should be done without truncation of the data beyond possible regions of artifacts from buffer changes or injections. Global analysis should be employed, which allows one to analyze all experimentally observed curves at all analyte concentrations simultaneously. This results in unambiguous best-parameter estimates for the binding constants, and provides residuals that should be inspected for comparison of the model and the data. Software needed for global analysis can be obtained from the manufacturer or as shareware. It should be noted that exclusion of specific data regions that may be poorly described by the model will introduce a bias into the analysis.

If the global analysis cannot be performed, and separate analyses of the individual binding curves of each experiment according to Equation 20.2.3 and Equation 20.2.4 are applied, then tests for consistency of the results are crucial (Schuck and Minton, 1996a). Important tests are: (1) the estimated extrapolated values of R_{assoc} ($t \rightarrow \infty$) at different concentrations should be consistent with a Langmuir isotherm for the estimated K_D (e.g., approaching half-saturation at $c_A = K_D$; see Figure 20.2.2); and (2) the extrapolated values of ($k_{assoc}c_A + k_{off}$) from the association phases should be consistent with the value of k_{off} as estimated in the dissociation phase. An analysis of the accuracy of the kinetic rate constants can be found in (Ober and Ward, 1999a).

Possible problems

The data may be only poorly described by Equation 20.2.3 and Equation 20.2.4 (leading to a poor fit and systematically distributed residuals) and instead show multiphasic behavior. Although it is in principle possible to apply global modeling with multiple binding-sites models, this is not recommended, because it is very difficult and can easily lead to very large errors (up to several orders of magnitude). Such modeling is usually not very robust, and many different models may fit the same data equally well (Glaser and Hausdorf, 1996). The reader is also advised to be extremely cautious with some of the implemented models in commercial or shared software, because they may not be valid descriptions of real surface binding processes (for example, mass transport models or models for bivalent analytes). Frequently, the deviations of the data from the single

BCU IAS / CENTRAL UNIVERSITY LIBRARY

exponential binding progress predicted in Equations 20.2.3 and Equation 20.2.4 are signatures of experimental artifacts, such as heterogeneity of the ligand (subpopulations of ligand with different binding properties through nonspecific immobilization), steric hindrance of binding to neighboring sites, or the presence of mass transport limitations or multivalent aggregates of the analyte (see discussion of Common Experimental Obstacles).

Steady-State Experiments and Binding Isotherm Analysis

This approach can yield both equilibrium constants and, if appended by a dissociation analysis, kinetic constants. Its main advantage with respect to the previously described technique (see discussion of Kinetic Analysis) is that it is much more robust and reliable because it is less affected by problems of potential multiphasic binding.

Experimental

If in the course of the association experiments a steady-state signal is observed, which is generally possible for interactions with relatively high k_{off}, then a binding isotherm can be constructed (Figs. 20.2.3 and 20.2.4). In an experimental procedure similar to the kinetic analysis, a concentration range as wide as possible should be covered, with two-fold concentration steps starting from both far below ($\leq 1/10$) K_D up to almost complete saturation of the surface sites, far above the K_D (≥ 10 times the K_D). The injection times required to attain steady state at the lower concentrations are longer (see Equation 20.2.3 and Equation 20.2.4), and exponential extrapolation may be used, in particular in the Biacore system, since the association times may be limited in the by the limited volume in the injection loop of the microfluidics. Exponential extrapolation is not advised, however, for concentrations above K_D.

For interactions that do not yield steady-state binding within a tolerable time interval for the association phase, or where the ligand does not withstand a regeneration procedure, equilibrium titration represents an experimental variant (Fig. 20.2.4). In this approach, the analyte concentration is increased in two-fold steps, allowing for attainment of steady state in each step, avoiding regeneration between the steps. This can be achieved by addition of a small aliquot of the analyte into a fixed volume of solution above the sensor surface (in cuvette-based sensors; Hall and Winzor, 1997), into a loop of recycling sample (slightly modified Biacore X; Schuck et al., 1998), or into the running buffer reservoir of a standard Biacore (Myszka et al., 1998). The fixed-volume techniques require far less sample volume.

After the highest analyte concentration has been applied, the dissociation phase can be observed and analyzed in terms of Equation 20.2.4. This can give an estimate of k_{off}, which can be used in conjunction with Equation 20.2.2 to calculate k_{on} as k_{off}/K_D.

Data analysis

Although the data analysis could in principle be performed by Scatchard analysis, this is not recommended for statistical reasons. A better method is a plot of $R_{steady\text{-}state}$ versus $\log(c_A)$, in which the K_D can be easily estimated as the inflection point at half saturation of the typical sigmoid isotherm (Fig. 20.2.4). The functional form for modeling is:

$$R_{steady-state}(c_A) = \frac{R_{max}}{1 + K_D/c_A}$$

Equation 20.2.5

Even if the data cannot be fitted well with this expression, the 50% saturation will still represent a good estimate of the order of magnitude of an average K_D. It is important,

BCU IAS / CENTRAL UNIVERSITY LIBRARY

however, in such an approach, to have enough data points at high analyte concentrations for a reliable estimate of R_{max} and the 50% saturation level, respectively. Then the robustness will be greater than that of the kinetic analysis of Equations 20.2.3 and Equation 20.2.4.

Competition Analysis

Competition experiments can be performed in different variations, but conceptually all use a calibration of the sensor signal as a function of free analyte concentration, followed

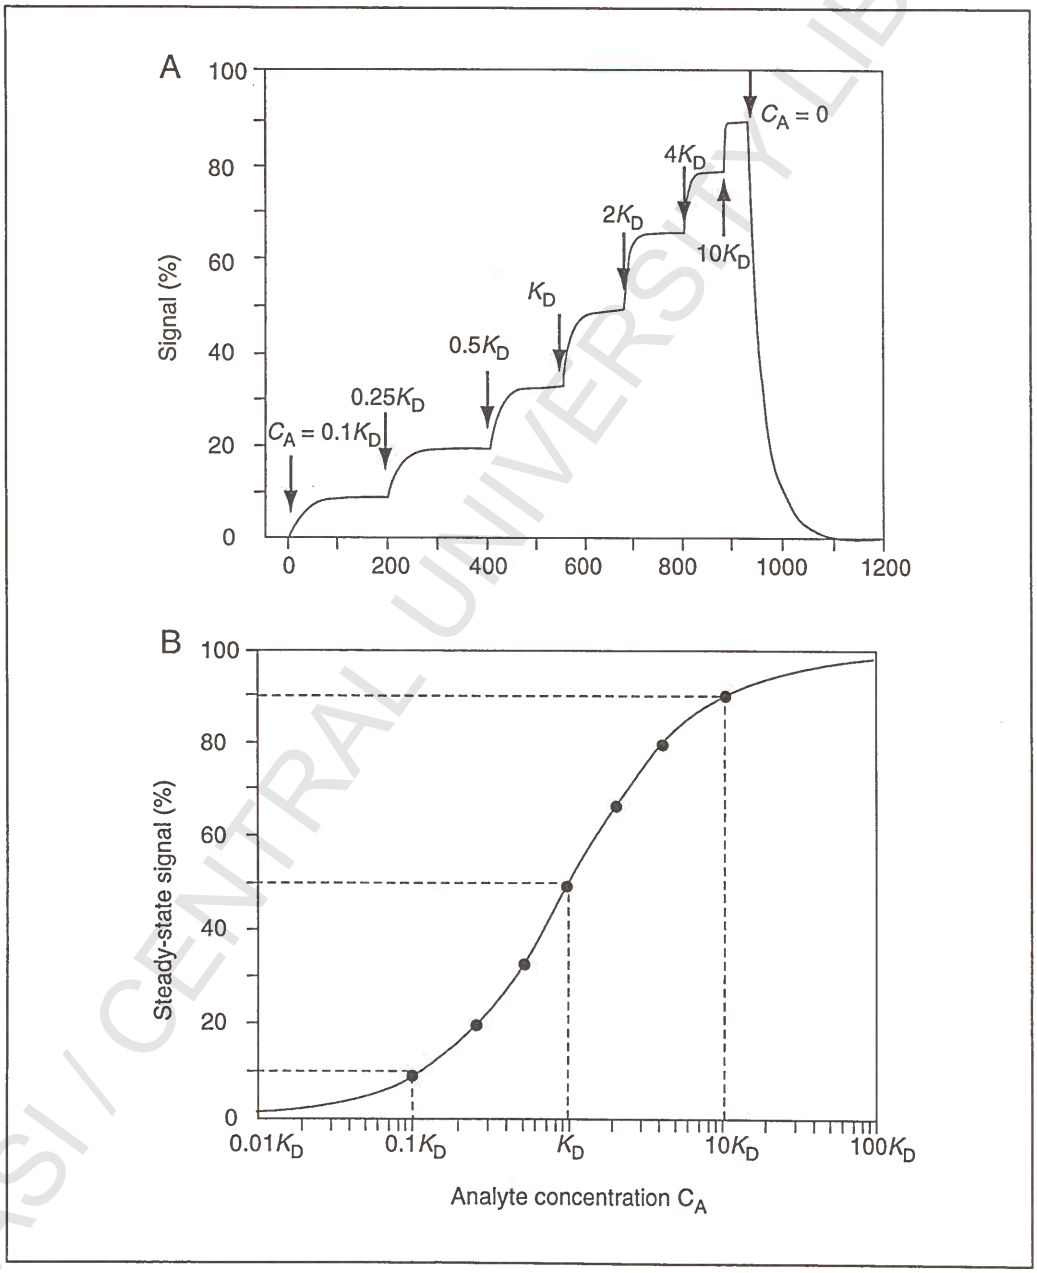

Figure 20.2.4 (**A**) Time course of an equilibrium titration experiment. Arrows indicate the time-points of the step-wise increase in the analyte concentration. (**B**) Steady-state binding analysis according to Equation 20.2.5. In a plot of the steady-state signal versus the base-10 logarithm of the analyte concentration, the binding isotherm exhibits a typical sigmoid shape. The inflection point at 50% saturation determines K_D, and the width of the curve is characterized by ~10% saturation at 1/10 K_D and ~90% saturation at 10 K_D (dotted lines). Visible inspection of the data in this representation already allows a robust parameter estimation.

BCU IASI / CENTRAL UNIVERSITY LIBRARY

by experiments with mixtures of analyte and soluble ligand in different molar ratios. The basic presumption is that the soluble ligand competes with the immobilized ligand for the free analyte, which leads to a reduction of the surface binding. This gives information on the solution affinity of ligand and analyte, while the freedom from the need to explicitly model the surface binding drastically diminishes the influence of potential surface artifacts on the results (Nieba et al., 1996; Schuck et al., 1998). This analysis can be extended to any other competitor that completely inhibits ligand binding of the analyte when bound to the analyte.

Experimental

For low-affinity systems with high chemical off-rate constants, in general, steady-state conditions can be achieved. Accordingly, the binding isotherm can be taken as a "calibration" of the sensor signal as a function of the free analyte concentration. Experiments to derive the surface binding constant can be conducted as described above (see Steady-State Experiments and Binding Isotherm Analysis). In a second variation, for high-affinity systems, mass-transport limited conditions are established by using a large immobilization density. Under these conditions, the initial binding rate constant will be directly proportional to the free analyte concentration ($dR/dt = k_t c_A$). The initial binding rate constant should be measured in equidistant concentration intervals for analyte concentrations up to a few times (two-fold) the K_D. After either one of these sets of calibration experiments, a set of experiments is performed using a constant concentration of analyte, $c_{A,tot}$ (which should be taken in the range of K_D), premixed and equilibrated with different concentrations of the soluble form of the ligand. The ligand concentrations, c_L, should be taken in two-fold steps, spanning the range from far below to far above the K_D. Choice of the fixed analyte concentration is important, since too high a value for $c_{A,tot}$ would show competition only in the range of stoichiometric binding. For systems that do not withstand regeneration, a recycling competitive titration procedure has been developed (Schuck et al., 1998).

Data analysis

For the high-affinity variant of the experiment with a linear initial rate of binding, $dR/dt = k_t c_A$, a plot of dR/dt versus c_A can be used to graphically calculate the amount of free analyte, $c_{A,free}$, during the competition experiment, or, $c_{A,free}$ is calculated according to the analytical inversion $c_{A,free}(c_L) = dR/dt(c_L)/k_t$. Similarly, in place of the linear function, an empirical calibration function for $dR/dt(c_A)$ could be used. The obtained concentration of free analyte $c_{A,free}$ in experiments at different soluble ligand concentrations c_L can be plotted as $c_{A,free}$ versus $\log(c_L)$, which gives a competition isotherm with the characteristic sigmoid shape. It can be fitted with Equation 20.2.6, the solution of the quadratic equation of the mass action law combined with mass balance:

$$c_{A,free} = c_{A,tot} - \frac{1}{2}\left(c_{A,tot} + c_L + K_D^{sol} - \sqrt{(c_{A,tot} + c_L + K_D^{sol})^2 - 4c_{A,tot}c_L}\right)$$

Equation 20.2.6

which gives the solution binding constant of analyte and ligand, K_D^{sol}. If the low-affinity variant of the experiment was used, the steady-state analysis of the sensor response in the absence of soluble ligand can be performed according to Equation 20.2.5, giving R_{max} and $K_D^{surface}$. This can be used in a direct analysis of the competition steady-state response using:

BCU IAS / CENTRAL UNIVERSITY LIBRARY

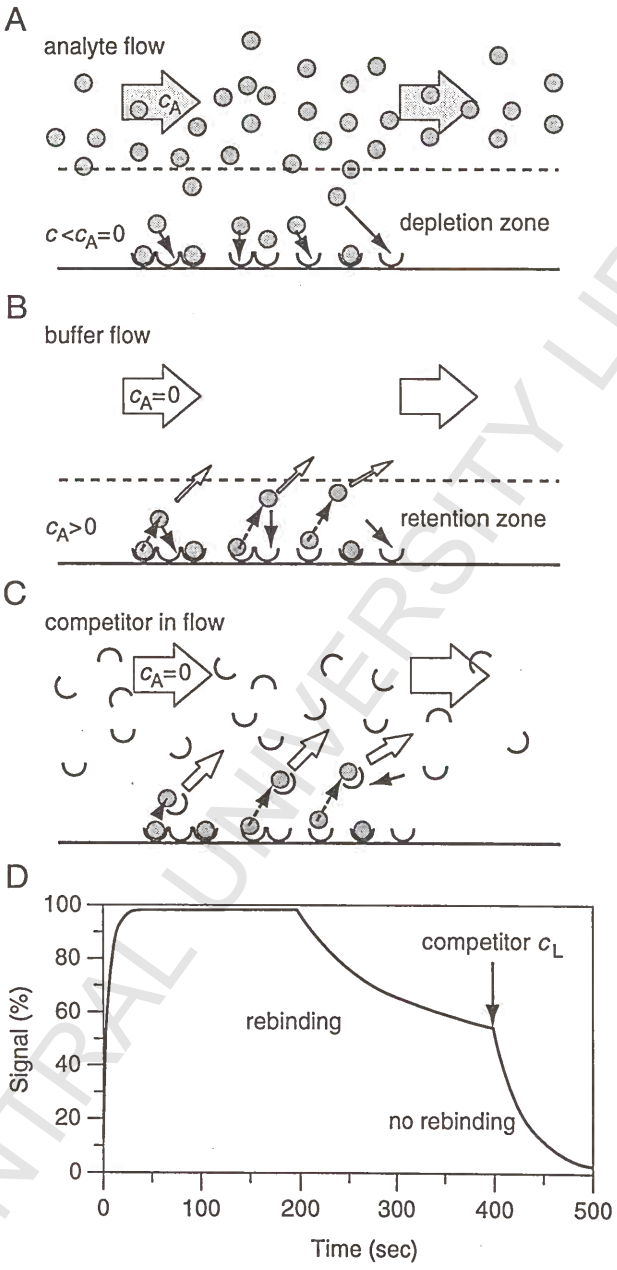

Figure 20.2.5 Mass transport effects on the surface binding process. (**A**) In the association phase, insufficient transport does not fully replenish the free analyte in a zone near the sensor surface (depletion zone). The inability to maintain the concentration c_A in the depletion zone leads to a limited surface binding rate. (**B**) The corresponding effect of mass transport limitation in the dissociation phase is that the surface is insufficiently washed and dissociated analyte is insufficiently removed. This generates a zone near the surface in which free analyte (after dissociation from the ligand) can rebind to empty ligand sites before diffusing into the bulk flow. This zone is indicated as retention zone. (**C**) Introduction of an excess of the soluble form of the ligand as a competitor into the buffer of the dissociation phase helps prevent rebinding to the surface. Soluble ligand can bind to dissociated analyte before rebinding takes place, and the soluble complex can diffuse into the buffer flow. This can allow the measurement of k_{off} free of mass transport effects. (**D**) Time course of dissociation during a mass transport induced rebinding situation (as depicted in panel B), and after introduction of a soluble competitor into the washing buffer (arrow). In the presence of the competitor, the signal reflects the chemical off-rate constant k_{off}, while in the rebinding situation, the apparent rate governing the signal is reduced.

BCU IAS CENTRAL UNIVERSITY LIBRARY

$$R(c_L) = \frac{R_{max}}{1 + K_D^{surf} / \left[c_{A,tot} - \frac{1}{2}\left(c_{A,tot} + c_L + K_D^{sol} - \sqrt{(c_{A,tot} + c_L + K_D^{sol})^2 - 4c_{A,tot}c_L} \right) \right]}$$

Equation 20.2.7

Alternatively, both titrations can be analyzed simultaneously in a global fit to both isotherms, assuming the binding constants to the surface sites and in solution to be identical.

COMMON EXPERIMENTAL OBSTACLES

Two of the most important experimental problems are mass transport limitations and the effect of aggregates on the binding kinetics. The first difficulty is found most frequently (but not exclusively) in systems of medium to high affinity with high k_{on}, whereas the second is observed predominantly in systems with lower affinity, where higher analyte concentrations are required. Other obstacles can be steric hindrance effects of binding to adjacent surface sites (O'Shannessy and Winzor, 1996), or the contribution of second-order kinetics to the binding process in cuvette systems (Edwards et al., 1998). Most of these processes scale with the immobilization level of the ligand. For this reason, a low ligand density is generally advantageous in minimizing potential problems. Special considerations for working at very low ligand densities are described in Ober and Ward (1999a,b). The use of control experiments (e.g., comparison of the K_D from solution competition experiments with the K_D obtained from surface binding kinetic measurements) is very useful in verifying the absence of artifacts. The role of mass transport and analyte aggregates will be explained in detail below.

Mass Transport Limitation

If the supply of analyte to the sensor surface is the limiting factor in the surface binding rate, the observed binding kinetics are mass transport limited. This will depend directly on both the density of the immobilized sites, and on the chemical on-rate constant of the interaction. In the association phase, this will produce a zone of depleted analyte concentration in the vicinity of the surface, while in the dissociation phase, this will lead to a zone of nonvanishing free analyte concentration, which is subject to rebinding-retention effect (Silhavy et al., 1975; Fig. 20.2.5). The quantitative influence of this process on the observed surface binding kinetics is governed by a highly complex reaction/diffusion/convection process (Yarmush et al., 1996; Schuck, 1996). Although the processes in the association and dissociation phase are conceptually closely related, it cannot be assumed that the ratio of the "apparent" rate constants still reflects a good estimate of the equilibrium constant. Also, it is strongly recommended that the nonspecialist reader refrain from modeling using mass-transport-corrected kinetic models.

Instead, the primary goal is to identify mass transport limitations, and to establish experimental conditions avoiding transport effects. The following is a list of diagnostic indicators, in the order of reliability, for mass transport limited binding.

1. *Dependence on surface capacity.* This is a very good indicator of mass transport limitation, since the transport limit always directly scales with the density of active surface sites. For this reason, variations of the immobilization density of the ligand are recommended as routine tests demonstrating the absence of transport limitation and other surface-related artifacts. This test can fail in the presence of significant non-specific analyte binding to the surface.

BOWLING GREEN STATE UNIVERSITY LIBRARY

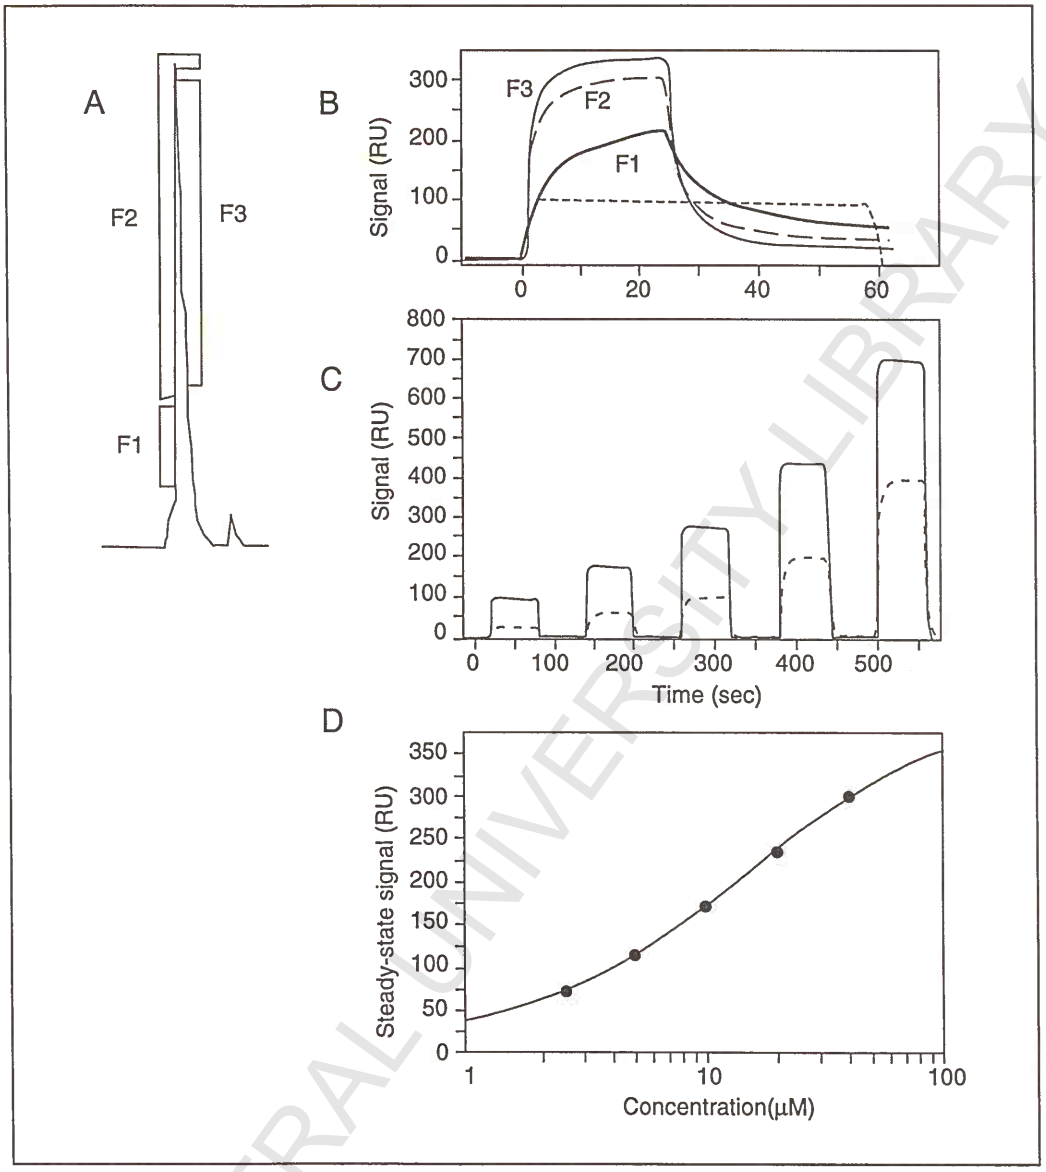

Figure 20.2.6 Exemplary data of the interaction of TCR with superantigen (for details of this interaction see Andersen et al., 1999). (**A**) Elution profile of the TCR from size-exclusion chromatography, indicating the fractions used for kinetic analysis of the interaction with immobilized superantigen, as shown in (**B**). It should be noted that fraction 1 (bold solid line), fraction 2 (dashed line), and fraction 3 (solid line) all exhibit multiphasic binding, with different relative magnitudes of the slower component. It should also be noted that despite the lower concentration of fraction 1, which results in the lowest response in the association phase, the signal in the dissociation phase is highest. This slower kinetic component in the binding progress curve reflects different amounts of aggregates bound to the sensor surface. The aggregates have a slower dissociation because of their multivalent attachment. For comparison, the same interaction is shown in the reverse orientation, with immobilized TCR and soluble superantigen (dotted line). (**C**) Sequence of association-dissociation curves at different superantigen concentrations, binding to immobilized TCR. In this orientation, the association and the dissociation is much faster, virtually monophasic, and the binding is completely reversible, which provides further evidence that the slow kinetic components introduced in the different fractions of the soluble TCR sample in Panel B are artifacts. For quantitative analysis, the signal measured at a nonfunctionalized surface (dotted line) is subtracted in order to remove the bulk refractive index contribution of the analyte. (**D**) A plot of the net steady-state binding signal versus superantigen concentration allows the measurement of the affinity of the interaction free from artifacts due to TCR aggregation that would be introduced in the configuration of Panel B.

BCU IAS CENTRAL UNIVERSITY LIBRARY

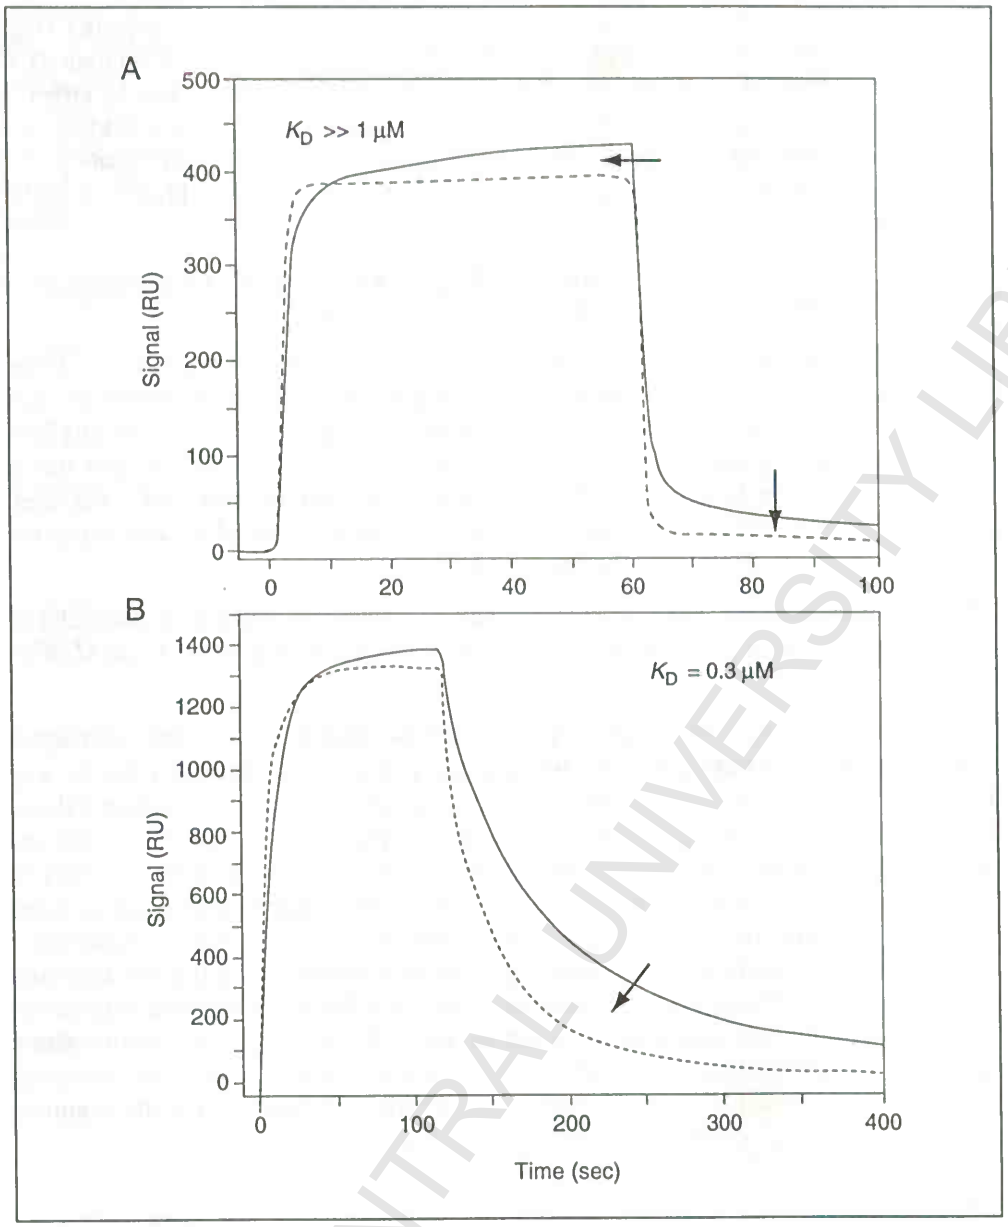

Figure 20.2.7 Effects of the ligand density on the binding kinetics for interactions with relative low affinity (**A**) and medium affinity (**B**). Each panel shows the interaction of immobilized superantigen with single-chain TCR, observed at high ligand surface density (1700 RU, solid lines) and low ligand surface density (700 RU, dashed lines). For easier comparison, the signal obtained at the lower density surface was scaled proportionally. In panel A, a slow phase of binding in the association phase and a residual binding (possible slow dissociation of multivalently bound aggregates) is introduced at high ligand density, under otherwise identical conditions. For the interaction in panel B, the chemical off-rate constant is smaller than for the low-affinity interaction shown above. Nevertheless, from comparison of the binding curves at different ligand surface densities (under otherwise identical conditions) it is obvious that an increased ligand density has significant effects on the surface binding kinetics. This observation could be due to aggregation or to mass transport limitations, both of which are more likely at higher ligand densities.

BCU IAS CENTRAL UNIVERSITY LIBRARY

2. *Increased dissociation rate when a soluble form of the ligand is injected (Fig. 20.2.5D).* This always strongly indicates rebinding (mass transport limitation) if detected. Since the ligand by itself should not interact with the surface, its effect is the binding to analyte near the sensor surface, preventing it from rebinding and allowing diffusion and washout from the surface (Fig. 20.2.5C). Unfortunately, this effect may not be present for large ligands or ligands/analytes with high nonspecific binding if they exhibit limited diffusivity.

3. *Double exponential dissociation phase.* This will be seen only after dissociation from more than 50% occupation of all available surface sites.

4. *Weak dependence on the flow rate (stirring speed in cuvette-based systems).* Since the transport parameters only change with the cube root of the flow rate, i.e., generating only a factor of 2 when changing the flow rate by a factor of 10, this flow rate dependency can be difficult to detect. This is particularly true if the flow rate is only varied by a factor of 2, and the reaction is only partially transport influenced. Then, only a ~10% change in the apparent k_{off} would be expected in cases where the true k_{off} is 100% larger than the apparent k_{off}.

5. *Linear association phase.* This effect may not always be present, in particular at substantial transport limitation (Schuck, 1996; Schuck, 1997b; Schuck and Minton, 1996b).

Generally, tests 1 and 2 are the most reliable. They also lead to experimental techniques that can be utilized to reduce or eliminate mass transport artifacts. The most effective way for reducing mass transport influence is lowering the surface density of the immobilized ligand. Higher flow rates give only comparatively very small improvements, but are connected with strongly increased sample volume requirements. If the surface density of the ligand cannot be reduced further without leading to an insufficient signal-to-noise ratio, then switching from kinetic experiments to steady-state or competition steady-state experiments is the best solution. This will give information on the equilibrium constant. The kinetic rate constants can then be estimated best from a saturation experiment (approaching complete saturation of all surface sites), followed by a dissociation phase during which soluble ligand is coinjected. The soluble ligand will minimize rebinding and allow the estimation of the chemical off-rate constant, from which the chemical on-rate constant can be determined via Equation 20.2.3.

Analyte Aggregates

Oligomeric aggregates of analyte can be troublesome in biosensor experiments in two different ways. First, if trace amounts of higher oligomers are present in the analyte sample, this will lead, in the association phase, to a slow accumulation at the sensor surface, which can be visible as a slower second phase of binding. As depicted in Figure 20.2.2, these multimeric analyte aggregates can have multiple interactions with immobilized ligand molecules, and therefore they will dissociate much more slowly than the monomeric analyte. Consequently, they will appear in the dissociation phase as a submoiety with a very low off-rate constant (Davis et al., 1998). The troublesome trace amounts of oligomers can be eliminated by careful chromatographic purification, or their influence can be minimized by exchanging the role of analyte and ligand (Davis et al., 1998; Andersen et al., 1999). This is illustrated in the example of Figure 20.2.6, which demonstrates the importance of both the sample preparation and the choice of ligand and analyte.

The second potentially problematic form of aggregation is a surface-induced multimerization of the analyte. Because the local macromolecular concentrations at the sensor surface are very high (e.g., in the order of 10mg/ml at a signal of 1000 RU in Biacore

BCU IASLIC CENTRAL UNIVERSITY LIBRARY

instruments), local crowding effects combined with non-specific interactions of the analyte can promote oligomer formation at the sensor surface (Fig. 20.2.7A; Minton, 1995, 1998). As with the influence of preformed aggregates, this process will lead to biphasic association and dissociation profiles, with the slower phase resulting from oligomer accumulation and dissociation, respectively. This process will be favored by higher surface concentrations—i.e., higher density of immobilized ligand, and by higher ligand affinity (Fig. 20.2.7). As with mass transport limitations, they can be detected by

Table 20.2.1 Troubleshooting Guide for Measuring Protein Interactions by Optical Biosensors

Problem	Solution
No electrostatic preconcentration achieved; poor immobilization	Desalt protein (e.g., using spin column or microdialysis); decrease pH of buffer used for immobilization (should be below pI of protein)
Nonspecific binding is high	Analyte may be too hydrophobic, or there may be electrostatic interaction with surface. Increase salt or detergent concentration in running buffer.[a]
High signal from buffer; refractive index changes	If this does not result from high analyte concentrations, dialyze the analyte against running buffer, or use a spin column for buffer exchange
Analyte does not come off after regeneration	Use increasingly harsher conditions for regeneration; test procedures used in affinity chromatography; check for strong nonspecific binding of the analyte; check for possible incomplete blocking of activated surface sites after immobilization
No binding of biotinylated sample to streptavidin surface	Check for presence of free biotin in sample. Biotin on the analyte may not be accessible by surface-immobilized streptavidin; in this case try biotinylated linker
Kinetics does not follow 1:1 binding	Check for mass-transport artifacts; check for possible traces of aggregates and for formation of aggregates at the surface; change immobilization method (avoid random coupling, avoid large surface densities). If this is not successful, go to steady-state analysis methods.
No steady-state binding is reached in a flow system	Use longer injections by increasing injection volume and/or decreasing flow rate. If sample volume is limiting, try an equilibrium titration
Mass transport limitation	Decrease immobilization density.[b] If immobilization density cannot be lowered further, go to steady-state analysis, combined with establishment of lower limit of k_{dis} from dissociation after saturation.
Increasing slope in the association phase	Potential signature of mass transport; lower the immobilization density
Increasing signal in the dissociation phase	Signature of mass transport limitation; lower the immobilization density

[a]Be aware of effects of nonspecific binding on the binding kinetics, which substantially decreases the diffusivity of the analyte across the sensor surface, potentially leading to mass transport artifacts that cannot be detected through change of the ligand density.

[b]Increasing the flow rate affects transport much less, but consumes much more sample.

BOWASI / CENTRAL UNIVERSITY LIBRARY

variation of the surface density of the ligand. They also can be reduced by lowering the surface density of the immobilized ligand, by size-exclusion chromatography immediately prior to the experiment, or by exchanging the role of ligand and analyte.

Troubleshooting

As with other complex biophysical techniques and all investigations involving biological samples, it is impossible to give guidelines which are even nearly complete or generally helpful for troubleshooting. Nevertheless, Table 20.2.1 presents a small list of possible solutions to potential problems, given in the hope that some readers may find them helpful.

SUMMARY

Binding studies with optical biosensors can be very powerful and versatile. Among the most important virtues are their high sensitivity and utility for a broad range of affinities, real-time detection allowing studies of binding kinetics, and relatively low requirements of sample volume. We have outlined some general strategies and described some of the most commonly used techniques. The work with protein interactions at a surface can introduce additional experimental difficulties as compared to solution methods. As a general rule in experiments with optical biosensors, it is highly recommended that analyses be performed in different ways so that the consistency of the results can be tested. Biosensors can be an excellent tool in the study of protein interactions, and become particularly powerful if combined with other methods.

ACKNOWLEDGMENT

The authors are grateful for helpful comments by D. Margulies in the preparation of the manuscript. They acknowledge D. Kranz and K. Karjalainen for providing the samples used for some of the experiments shown. Peter Andersen acknowledges grant support by the Danish Natural Sciences Research Council.

Common Conversion Factors

Table A.1D.1 lists some of the more common conversion factors for units of measure used throughout Current Protocols manuals, while Table A.1D.2 gives prefixes indicating powers of ten for SI units.

Table A.1D.3 gives conversions between temperatures on the Celsius (Centigrade) and Fahrenheit scales. Celsius temperatures are converted to Fahrenheit temperatures by multiplying the Celsius figure by 9, dividing by 5, and adding 32, or by multiplying the Celsius figure by 1.8 and adding 32. Fahrenheit is converted to Celsius by subtracting 32 from the Fahrenheit figure, multiplying by 5, and dividing by 9. In Table A.1D.3, the center figure represents the temperature one has read on one of the scales; the figure to the left is the conversion of that figure into Celsius if read in Fahrenheit, while that to the right represents the conversion to Fahrenheit if read in Celsius: e.g., the temperature 88 Fahrenheit converts to 31.1°C, while the temperature 88 Celsius converts to 190.4°F.

SUPPLEMENT INDEX

How to Use This Index

A new main index is provided once a year. Thereafter, with the next three supplements, a cumulative supplement index, which amends the main index, will be provided. Thus, readers should consult both the main index and the supplement index when seeking an entry, as page numbers may change for replacement units and new entries will added.

A

Acid digesting-ninhydrin assay, peptide synthesis, 18.5.15
Adherent cells, pulse labeling with [^{35}S]methionine, 3.7.4
Amine coupling, 20.2.7
Amino acids, labeling
  cell density, 3.7.10
  generally, 3.7.1–3.7.2, 3.7.8
  long-term labeling with [^{35}S]methionine, 3.7.5–3.7.6
  pH and, 3.7.10
  pulse-chase labeling of cells with [^{35}S]methione, 3.7.5
  pulse-labeling of adherent cells with [^{35}S]methione, 3.7.4
  pulse-labeling of cells in suspension with [^{35}S]methione, 3.7.2–3.7.4
  selection of label, 3.7.8–3.7.9
    TCA precipitation to determine label incorporation, 3.7.7
  temperature and, 3.7.10
  time factor, 3.7.9
Avidin-biotin coupling, 20.2.7–20.2.8

B

Binding, protein-protein interactions
  competition analysis, 20.2.12–20.2.15
  experiments and data analysis, 20.2.8
  isotherm analysis, 20.2.11–20.2.12
  kinetic analysis, 20.2.9–20.2.11
  multivalent, 20.2.4–20.2.5
  nonspecific, 20.2.5–20.2.6
  steady-state experiments, 20.2.11–20.2.12
Boc, *see t*-butyloxycarbonyl
t-butyloxycarbonyl
  direct synthesis, of MAP systems, 18.5.5–18.5.8
  indirect synthesis
    using carbonyl chemistry, 18.5.13–18.5.14
    using thiol chemistry, 18.5.11–18.5.13

C

Celsius temperatures, conversion to Fahrenheit, A.1D.7–A.1D.8
Chromatography
  high-performance gel-filtration, 18.5.16, 18.5.33
  to measure protein interactions, 20.1.1, 20.1.6, 20.1.8
Coimmunoprecipitation, *see* Coprecipitation
Contaminants, in assessment of protein interaction, 20.1.7
Conversion charts
  Celsius/Fahrenheit temperature, A.1D.7–A.1D.8
  units of measurement, A.1D.1–A.1D.5
Coprecipitation, to identify protein-protein interactions
  GST fusion proteins, 19.4.6
  protein A/G-Sepharose, 19.4.4.–19.4.6, 19.4.8
  specificity of interactions, control tests, 19.4.4
  whole-cell extracts, preparation of, 19.4.2–19.4.4, 19.4.7–19.4.8
Cyclic multiple antigen peptide (cMAP)
  end-to-end cyclic peptides, preparation via an
    X-Cys ligation site, 18.5.23–18.5.24
    X-thiaproline ligation site, 18.5.24–18.5.25
  end-to-end, indirect preparation using thiol chemistry, 18.5.21–18.5.23
  end-to-side chain cyclic peptides, preparation via a thiazolidine or oxime linkage, 18.5.25–18.5.26
  generation of, 18.5.4
  synthesis
    direct, of end-to-side chain, 18.5.16–18.5.18
    Fmoc, of side chain-to-side chain using carbonyl chemistry, 18.5.19–18.5.21
    preparation, 18.5.30
    reactions, 18.5.32
  See also Multiple antigenic peptide system
Cyclic peptides, applications of, 18.5.2

D

Dialysis
  equilibrium, 20.1.9
  of MAP system, 18.5.15–18.5.16

F

Fahrenheit temperatures, conversion to Celsius, A.1D.7–A.1D.8
9-Fluorenylmethylcarbonyl
  direct synthesis of MAP systems, solid phase, 18.5.8–18.5.10
  indirect synthesis
    using carbonyl chemistry, 18.5.13–18.5.14
    using thiol chemistry, 18.5.11–18.5.13, 18.5.32–18.5.33
  solid-phase peptide synthesis (SPSS), schedule for, 18.5.9 (table)
Fmoc, *see* 9-Fluorenylmethylcarbonyl
Fusion proteins, GST, coprecipitating, 19.4.6

G

Gel-filtration chromatography, in MAP system purification, 18.5.16, 18.5.33

I

Immobilization techniques, protein-protein interactions
  amine coupling, 20.2.7
  avidin-biotin coupling, 20.2.7–20.2.8
  streptavidin-biotin coupling, 20.2.7–20.2.8
  susceptibility to, 20.2.5–20.2.6
  thiol-disulfide exchange coupling, 20.2.8
Isotherm analysis, protein-protein interactions, 20.2.11–20.2.12

K

Kinetic analysis, protein-protein interactions, 20.2.9–20.2.11

L

Labeling, metabolic, of amino acids, UNIT 3.7
Light scattering, to quantitate protein interactions, 20.1.8

M

Mass transport, limitations in protein-protein interactions, 20.2.15, 20.2.18
Measurement units, conversion chart, A.1D.1–A.1D.5
Multiple antigenic peptide (MAP) system
  applications of, 18.5.1–18.5.2, 18.5.28
  ninhydrin test, 18.5.15
  overview, 18.5.28
  purification
    by dialysis, 18.5.15–18.5.16
    using gel-filtration chromatography, 18.5.16
  schematic drawing of, 18.5.2 (fig.)
  synthesis
    Boc synthesis, 18.5.5–18.5.8, 18.5.11–18.5.14
    chemistry of, 18.5.29
    Fmoc solid-phase synthesis, 18.5.8–18.5.14
    generally, 18.5.3–18.5.5
    ligation methods, 18.5.31–18.5.32
    methodology, 18.5.29–18.5.31
    preparation for, 18.5.3–18.5.5
Multivalent binding, protein-protein interactions, 20.2.4–20.2.5

N

Ninhydrin, *see* Acid digestion-ninhydrin assay
Nonspecific binding, protein-protein interactions, 20.2.5–20.2.6

O

Oligomeric proteins, analyte aggregates in protein-protein interactions, 20.2.17 (fig.), 20.2.18–20.2.19
Optical biosensors, in measurement of protein interactions
  binding
    competition analysis, 20.2.12–20.2.15
    experiments and data analysis, 20.2.8
    isotherm analysis, 20.2.11–20.2.12
    kinetic analysis, 20.2.9–20.2.11
    multivalent, 20.2.4–20.2.5
    nonspecific, 20.2.5–20.2.6
    steady-state experiments, 20.2.11–20.2.12
  concentration, 20.2.3–20.2.4

coupling
avidin-biotin, 20.2.7–20.2.8
streptavidin-biotin, 20.2:7–20.2.8
thiol-disulfide exchange, 20.2.8
development of, generally, 20.2.3
immobilization
protocols, 20.2.6–20.2.8
susceptibility to, 20.2.5–20.2.6
obstacles, common experimental
analyte aggregates, 20.2.18–20.2.19
mass transport limitations, 20.2.15, 20.2.18
oligometric structure, 20.2.4–20.2.5
purity, 20.2.4
reactive properties, 20.2.5–20.2.6
regeneration, 20.2.5–20.2.6
schematic representation, 20.2.2 (fig.)
size, 20.2.3–20.2.4
stoichiometry, 20.2.4–20.2.5
troubleshooting guide, 20.2.19 (table)
volume, 20.2.3–20.2.4

P

Peptide dendrimers, synthesis and application as protein mimetics, UNIT 18.5
Peptides, preparation and handling in synthesis and applications of peptide dendrimers as protein mimetics, UNIT 18.5
Protein A/G-Sepharose, coprecipitation, 19.4.4–19.4.6, 19.4.8
Protein interactions,
identification of
basic concepts, UNIT 19.1
by coprecipitation, UNIT 19.4
by interaction trap/two hybrid system, UNIT 19.2
phage-based expression cloning, UNIT 19.3
quantitation of, overview
characterizing, methodology summary, 20.1.2–20.1.3 (table)
contaminants and protein quality, sensitivity to, 20.1.7
data analysis methods, importance of, 20.1.6
methodology, selection of, 20.1.8–20.1.9
multiple techniques, benefits of, 20.1.8
recombinant proteins, research value, 20.1.7–20.1.8
techniques, 20.1.1–20.1.6
thermodynamic linkage relationships, 20.1.9–20.1.10
quantitation techniques
by optical biosensors, UNIT 20.2
Protein mimetics, peptide synthesis and applications as, UNIT 18.5
Protein-protein interactions, detection by coprecipitation, UNIT. 19.4
by interaction trap/two hybrid system, UNIT 19.2
phage-based expression cloning, UNIT 19.3
Proteins, radiolabeled, UNIT 3.7
Pulse-chase labeling of cells with [^{35}S]methionine, 3.7.5
Pulse-labeling, amino acids with [^{35}S]methionine
of adherent cell, 3.7.4
of suspended cells, 3.7.2–3.7.4
Purification, of MAP system, 18.5.15–18.5.16, 18.5.33

R

Radiolabeled amino acids
concentration and specific activity of, 3.7.9
long-term labeling with [^{35}S]methionine, 3.7.5–3.7.6
metabolic labeling of proteins, use in, 3.7.1 (table)
pulse-chase labeling of cells with [^{35}S]methionine, 3.7.5
pulse-labeling
of adherent cells with [^{35}S]methioninee, 3.7.4
in suspended cells in [^{35}S]methionine, 3.72.–3.7.4
Reagents and solutions
acetal resin, 18.5.26
Boc-aminooxyacetic acid, 18.5.26
Boc-succinic acid hydrazide, 18.5.26–18.5.27
chase medium, 3.7.7
cleavage solution for Fmoc protecting group, 18.5.27
co-immunoprecipitation buffer, 19.4.6
gluthione-agarose or gluthione-Sepharose slurry, 19.4.7
long-term labeling medium (90% methionine-free medium), 3.7.7
ninhydrin test reagents, 18.5.27
protease inhibitor mix, 100×, 19.4.7
protein A/G-Sepharose slurry, 19.4.7
pulse-labeling medium, 3.7.8
sulfhydryl reducing solution, 18.5.27
thiobenzhydryl resin 2 for C-terminal thioacid, 18.5.27
thioester resin (HS-CH_2CH_2CO-MBHA-resin 1) for C-terminal thioester, 18.5.27–18.5.28
trichloroacetic acid (TCA) solutin, 10% sign (w/v), 3.7.8
Recombinant proteins, interaction, quantitation of, 20.1.7–20.1.8
Regeneration, protein-protein interactions, 20.2.5–20.2.6
Resonant mirror, 20.2.1

S

[^{35}S]cysteine, 3.7.6, 3.7.8
[^{35}S]methionine
pulse-labeling, 3.7.2–3.7.6
safety precautions, 3.7.2
Sedimentation velocity, 20.1.4–20.1.5
Sedimentation equilibrium, 20.1.4–20.1.5
SI units, power of ten prefixes, A.1D.6
Size-exclusion chromatography (SEC), 20.1.1, 20.1.8
Solid-phase peptide synthesis (SPPS)
Boc, 18.5.5–18.5.8, 18.5.13
Fmoc, 18.5.8–18.5.10, 18.5.13
Steady-state experiments, protein-protein interactions, 20.2.11–20.2.12
Stoichiometry, protein-protein interactions, 20.2.4–20.2.5
Streptavidin-biotin coupling, protein-protein interactions, 20.2.7–20.2.8
Surface plasmon resonance (SPR)
applications, generally, 20.1.1, 20.1.4
to quantitate protein interactions, 20.2.1
Synthesis, peptides, preparation and handling, UNIT 18.5

T

Temperature, Celsius/Fahrenheit conversion charts, A.1D.7–A.1D.8
Thermodynamics, in protein interactions, 20.1.9–20.1.10
Thioanisole, 18.5.33
Thiol-disulfide exchange coupling, protein-protein interactions, 20.2.8
Titration microchemistry, 20.1.5–20.1.6
Trichloroacetic acid (TCA), precipitation to determine incorporation of radioactivity, 3.7.7
Trifluoroacetic acid (TFA), Fmoc peptide synthesis, 18.5.32–18.5.33

U

Ultracentrifugation, analytical, 20.1.4–20.1.5
Useful data
Celsius/Fahrenheit temperature, A.1D.7–A.1D.8
unit of measurement, A.1D.1–A.1D.5
power of ten prefixes for SI units, A

W

Waveguide biosensors, 20.2.1

BCU IASI / CENTRAL UNIVERSITY LIBRARY

Measurement of Radioactivity

The SI unit for measurement of radioactivity is the Becquerel:

1 Becquerel (Bq) = 1 disintegration per second

The more commonly encountered unit is the Curie (Ci):

1 Ci = 3.7×10^{10} Bq
= 2.22×10^{12} disintegrations per minute (dpm)
1 millicurie (mCi) = 3.7×10^{7} Bq = 2.22×10^{9} dpm
1 microcurie (μCi) = 3.7×10^{4} Bq = 2.22×10^{6} dpm

Conversion factors:

1 day = 1.44×10^{3} min = 8.64×10^{4} sec
1 year = 5.26×10^{5} min = 3.16×10^{7} sec
counts per minute (cpm) = dpm/(counting efficiency)

Physical Characteristics of Commonly Used Radionuclides

Nuclide	Half-life	Emission	Range of emission, max
^{3}H	12.43 years	β	0.42 cm (air)
^{14}C	5370 years	β	21.8 cm (air)
^{32}P	14.3 days	β	610 cm (air)
			0.8 cm (water)
			0.76 cm (plexiglass)
^{35}S	87.4 days	β	24.4 cm (air)
^{125}I	60 days	γ	0.2 mm (lead)
^{131}I	8.04 days	β	165 cm (air)
		γ	2.4 cm (lead)
